A significant relation was observed between the duration of diastolic turbulence in the right ventricular outflow tract, expressed as a fraction of diastole, and the severity of pulmonary hypertension (Fig. 4). Mean pulmonary arterial pressure was 40 mm Hg or greater in 83 percent of the patients with diastolic turbulence persisting for more than two thirds of diastole, in 3 percent of patients with turbulence lasting for one third to two thirds of diastole and in none of the patients with turbulence lasting one third or less of diastole ($p < 0.001$).

TABLE II

Tricuspid Insufficiency on Doppler Echocardiography: Relation to Right Ventricular Hypertension

	Patients With TI (n = 61)		Patients Without T (n = 59*)	
	n	%	n	%
RVP >35 mm Hg (n = 77)	55	90	22	37
RVP <35 mm Hg (n = 43)	6	10	37	63
			$p < 0.01$ (chi-square analysis)	

* Includes the 20 patients without heart disease.
RVP = right ventricular systolic pressure; TI = tricuspid insuf ciency.

TABLE III

Pulmonary Insufficiency on Doppler Echocardiography: Relation to Pulmonary Hypertension

	Patients With PI* (n = 44)		Patients Without PI (n = 64†)	
	n	%	n	%
Mean PAP >22 mm Hg (n = 62)	38	86	24	38
Mean PAP <22 mm Hg (n = 46)	6	14	40	62
		p <0.01		

* Excludes three patients with pulmonary valvotomy. † Includes 20 patients without heart disease.
PAP = pulmonary arterial pressure; PI = pulmonary insufficiency.

Pulsed Doppler versus M mode echocardiographic prediction of pulmonary hypertension: The sensitivity and predictive values of the pulsed Doppler and the M mode echocardiographic findings for pulmonary hypertension are listed in Table IV. In the absence of pulmonary stenosis, pulsed Doppler evidence of tricuspid or pulmonary insufficiency, or both, had a sensitivity of 87 percent and a predictive value of 87 percent for pulmonary hypertension. The occurrence of both Doppler abnormalities together had a sensitivity of 41 percent and a predictive value of 90 percent. In contrast, M mode echocardiographic evidence of right ventricular enlargement (greater than 2.8 cm, left lateral recumbent position) occurred in only 31 percent of patients with pulmonary hypertension; the predictive value of this finding was 93 percent. A reduced amplitude (less than 2 mm) of the pulmonary valve *a* wave had a sensitivity and predictive value comparable with those of the pulsed Doppler finding of tricuspid or pulmonary insufficiency, or both. However, analysis of the pulmonary valve echo for this abnormality was possible in only 31 of 92 patients with heart disease.

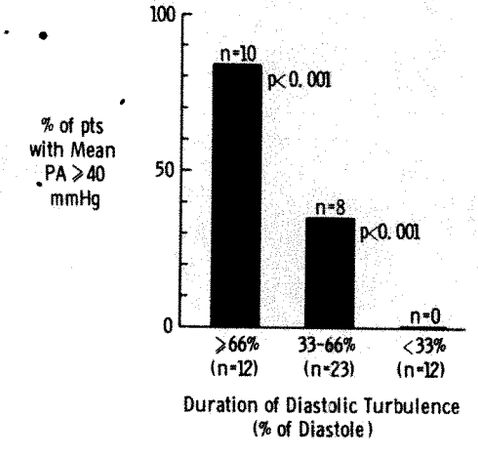

FIGURE 4. Incidence of mean pulmonary arterial pressures (PA) greater than 40 mm Hg in patients (pts) with pulmonary insufficiency on Doppler study in relation to the duration of diastolic turbulence in the time interval histogram.

TABLE IV

Sensitivity and Predictive Value of Pulsed Doppler and M Mode Echocardiography in Pulmonary Hypertension in the Absence of Pulmonary Stenosis

	Sensitivity		Predictive Value	
	n	%	n	%
Doppler				
TI, PI or both	60/69	87	60/69	87
TI and PI	28/69	41	28/31	90
M Mode				
RVE	26/69	38	26/28	93
PV *a* wave 2 mm or less*	18/21	86	18/20	90

* Analysis of pulmonary valve (PV) *a* wave could be performed in only 31 of 92 patients with heart disease without pulmonary stenosis.
PI = pulmonary insufficiency; RVE = right ventricular enlargement (2.8 cm or greater, left lateral recumbent position); TI = tricuspid insufficiency.

Discussion

Diagnostic specificity and sensitivity: The results of this investigation reveal that pulsed Doppler echocardiographic evidence of systolic turbulence in the right atrium and diastolic turbulence in the right ventricular outflow tract indicate tricuspid and pulmonary insufficiency, respectively. Each Doppler flow abnormality was associated with its corresponding valve lesion in the experimental animal studies. Furthermore, the presence of systolic turbulence on Doppler recording in the right atrium correlated with angiographic evidence of tricuspid insufficiency in 17 of 17 patients, with a sensitivity of 94 percent. All 12 patients with clinical features of tricuspid regurgitation and the 3 patients with a typical murmur of pulmonary insufficiency after valvotomy had Doppler evidence of tricuspid or pulmonary insufficiency, respectively. The absence of false positive findings in the patients with a normal angiogram and the absence of either tricuspid or pulmonary regurgitation on Doppler recording in the 20 patients without heart disease suggest a high clinical specificity of Doppler echocardiography for these lesions.

Unfortunately, there is no perfect "gold standard" for right-sided valve regurgitation. Cineangiography is probably extremely sensitive, but the presence of a catheter across a valve has been considered a potential source of artifactual regurgitation.[11,12] No evidence of tricuspid or pulmonary regurgitation was observed in our experimental studies on either pulsed Doppler or contrast echocardiography before surgical disruption of the valve despite the presence of a catheter across both valves. The chances of artifactual tricuspid regurgitation in our clinical angiographic studies were minimized by using an angiographic catheter with side holes, injecting at low flow rates and excluding ventricular ectopic beats from evaluation. Pulmonary angiography was not used to assess the presence of pulmonary insufficiency because of the potential risks associated with pulmonary hypertension.[23] Although contrast echocardiography with peripheral venous injection has been shown to detect tricuspid insufficiency, its sensitivity to mild degrees of insufficiency has not been validated.[24]

Comparison with left-sided regurgitant lesions: The Doppler flow disturbances described in this investigation in association with tricuspid or pulmonary insufficiency are very similar to their left-sided counterparts. Thus mitral regurgitation is associated with systolic turbulent flow in the left atrium behind the mitral valve whereas aortic insufficiency results in diastolic turbulent flow in the left ventricular outflow just below the aortic valve.[14] Previous studies from this laboratory[22] and others[17,18] comparing pulsed Doppler recording with contrast angiography established a high sensitivity and specificity of the pulsed Doppler findings to these left-sided regurgitant lesions. Because the principles of pulsed Doppler flow apply equally well (if not better by virtue of proximity of structures to the transducer) to the right side of the heart, the presence of systolic right atrial or diastolic right ventricular outflow turbulence has been presumed to indicate right-sided valve regurgitation[14]; the experimental and clinical results of our investigation further support this assumption. However, other unusual lesions may at times mimic the Doppler findings described in this investigation. Thus systolic turbulence in the right atrium may be observed in the presence of a shunt from the left ventricle to the right atrium, and diastolic turbulence in the right ventricular outflow tract may occur with a communication from the aorta to the right ventricle.

Correlation with auscultatory findings: In a simplified way, pulsed Doppler echocardiography may be considered analogous to intracardiac phonocardiography because it allows sampling within discrete intracardiac regions and thus localization of the sources of murmurs. However, although murmurs are vibrations in an audible frequency range induced by turbulent flow, the Doppler shifts represent minute changes in the frequency of reflected sound waves in an ultrahigh frequency range (megahertz) also induced by flow dynamics. Therefore, it is possible for the turbulence produced by small amounts of regurgitant flow across a relatively low pressure system (such as right ventricle to right atrium or pulmonary artery to right ventricle) to be insufficient in magnitude to induce audible vibrations but adequate to cause a frequency dispersion of the reflected sound waves. This appears to be the case in our patients in whom the incidence of tricuspid or pulmonary insufficiency on Doppler recording was considerably greater than on auscultation.

The clinical subtleties of right-sided regurgitant lesions have previously been well recognized.[2,3] Ahn and Segal[2] reported that the murmur of tricuspid insufficiency may disappear as right-sided dilatation occurs or with development of a "patent foramen ovale." The murmur of pulmonary insufficiency associated with pulmonary hypertension may mimic the murmur of aortic insufficiency.[3] There was a large incidence of aortic regurgitation in our patients, and this may have obscured the auscultatory recognition of pulmonary insufficiency.

Correlation with intracardiac pressures: Increased pressure in the right ventricle or pulmonary artery was present in 90 and 86 percent of patients with Doppler evidence of tricuspid or pulmonary insufficiency, respectively, and this finding suggests a causal relation between high pressure states and mild degrees of right-sided valve regurgitation as detected by pulsed Doppler recording. Functional tricuspid and pulmonary insufficiency have been well recognized in pressure overload states.[5,25,26] Our findings suggest that mild degrees of valve regurgitation occur more often than previously appreciated. The absence of diagnostic physical findings in many of these patients corroborates the hemodynamic insignificance of this abnormality. However, because of the frequency of its occurrence (8 percent) and the high association with pressure overload state (87 percent), pulsed Doppler detection of tricuspid or pulmonary insufficiency, or both, in the absence of

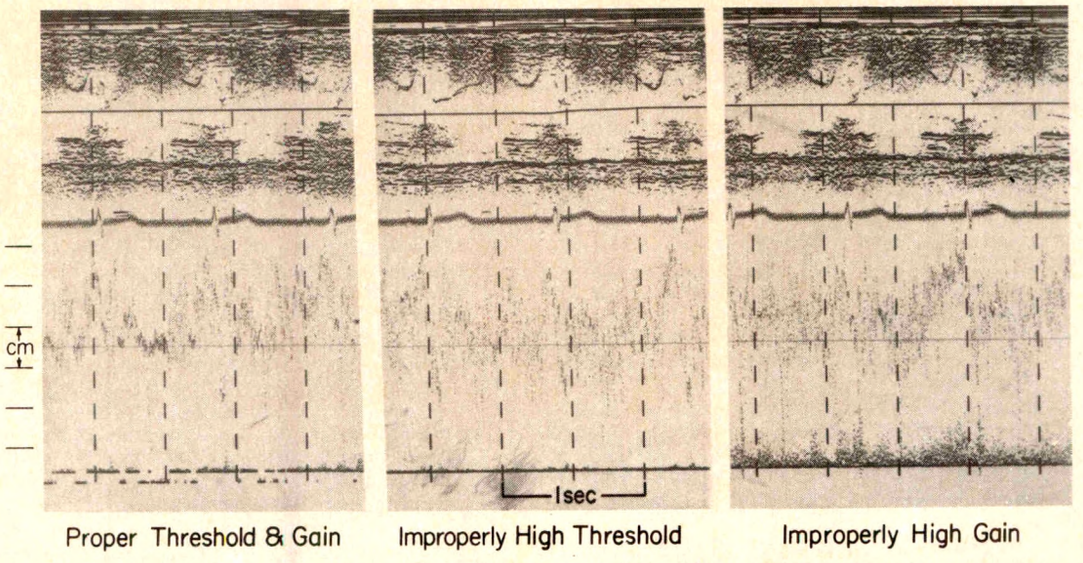

FIGURE 5. Effects of threshold and gain settings on the time interval histographic output. In the **middle and right panels,** the threshold and gain settings are inappropriately high, with excessive signals suggesting turbulence. The **left panel** shows the proper recording and appropriate threshold and gain settings in a patient without tricuspid insufficiency.

pulmonary stenosis was superior to M mode echocardiographic assessment of right ventricular size or pulmonary valve motion in the prediction of pulmonary hypertension. In addition, measurements of the duration of pulmonary insufficiency (as a fraction of diastole) allowed a gross estimation of the severity of pulmonary hypertension (mean pulmonary arterial pressure above or below 40 mm Hg).

Limitations of the technique: In its present form, pulsed Doppler echocardiography is limited in the quantification of valve regurgitation. Hemodynamically insignificant degrees of regurgitation involving any of the cardiac valves may produce frequency dispersions on the time interval histogram comparable with those seen with hemodynamically significant valve lesions. When valve regurgitation is recognized by pulsed Doppler study, other indirect echocardiographic variables (chamber size, wall motion) may be more useful to assess severity. In the case of right-sided valve regurgitation, the main clinical contribution of the pulsed Doppler technique is related to the detection of pulmonary hypertension because these lesions are often hemodynamically insignificant. Interestingly, in aortic stenosis (a high flow velocity state), pulsed Doppler assessment of the duration and amplitude of turbulence in the ascending aorta has been used successfully in differentiating aortic valve areas above from those below 1.0 cm^2[2,16].

Our use of objective analysis of the time interval histogram in this study should not imply that the technique is free of all subjectivity. A proper pulsed Doppler echocardiographic examination requires interpretation by the operator of the various audio signals emitted by cardiac valves and heart walls as well as differentiation of turbulent from nonturbulent blood flow. Moreover, proper settings of threshold and gain levels are important in obtaining the most optimal graphic display of the Doppler shifts (Fig. 5). Thus technical expertise remains an important factor in the proper use of this new noninvasive technique.

Implications: Pulsed Doppler echocardiography appears to be sensitive and specific in detecting right-sided valve regurgitation. The importance of these findings is related to the observation that in the absence of primary valve disease, evidence of tricuspid or pulmonary insufficiency, or both, on Doppler study was a frequent marker of pulmonary hypertension. This makes pulsed Doppler echocardiography superior to clinical auscultation and M mode echocardiography in the evaluation of patients in whom pulmonary hypertension is suspected.

Radionuclide gated cardiac blood pool imaging was used to quantify th severity of valve regurgitation in 20 patients, by calculating the ratio left ventricular to right ventricular stroke counts (end-diastolic minu end-systolic counts in right and left ventricular regions of interest). Th ratio (the stroke index ratio) was substantially higher in patients with aort and mitral regurgitation (3.91 ± 1.45) than in a control group of 10 patien without regurgitation (1.32 ± 0.15), p <0.001. The stroke index rat correlated closely (r = 0.947) with measurements of regurgitant fracti derived from simultaneous determinations of total and forward strok volumes during cardiac catheterization.

After aortic and mitral valve replacement in 18 patients, the stroke inde ratio decreased from 4.03 ± 1.46 to 1.38 ± 0.23 (p <0.001), a value n significantly different from that observed in patients without regurgitatio All three patients with residual postoperative regurgitation had a strok index ratio greater than 2 standard deviations above the mean values f the control group (>1.62), whereas the remaining 15 patients, who ha no evidence of regurgitation, had values within the normal rang Therefore, radionuclide gated blood pool scanning provides a noninvasiv method of quantifying valve regurgitation and assessing the results medical or surgical interventions.

Evaluation of the severity of aortic and mitral regurgitation is an im portant clinical problem. Although auscultation remains the standa noninvasive method of diagnosing both the presence and the site regurgitation, quantification of the magnitude of regurgitation requir the simultaneous invasive determination of the total and forward stro volumes of the left ventricle.[1] Because of the difficulties of this metho valve regurgitation is most frequently assessed qualitatively by a su jective evaluation of the magnitude of the regurgitant jet after contra cineangiography. A less invasive and more accurate method of quan fying valve regurgitation is clearly needed.

Rigo et al.[2] recently introduced a noninvasive method of quantifyi left-sided regurgitant lesions with radionuclide angiocardiography. Wi this technique, the change in counts between diastole and systole ov the left and right ventricles is calculated and expressed as a ratio (t stroke index ratio). Because in normal persons the right ventricul stroke volume is equal to the left ventricular stroke volume, the stro index ratio should be unity in patients without regurgitant lesions a should be substantially greater than 1 in patients with significant aort or mitral regurgitation. In the study of Rigo et al., the left ventricula right ventricular stroke index ratio in normal subjects (1.15 ± 0.1 differed significantly from that in patients with mild (2.15 ± 0.48) severe regurgitation (4.00 ± 1.15). A similar relation between the r dionuclide stroke index ratio and the angiographic estimation of t magnitude of valve regurgitation was recently confirmed by Lam al.[3]

Clinical use of this noninvasive technique requires further validation of the stroke index ratio. Previous investigations in patients correlated this ratio only qualitatively, that is, derived indexes were compared with subjective assessment of the magnitude of the angiographically visualized regurgitant jet. Validation of this ratio with electromagnetic flowmeter studies has recently been reported in dogs,[4] but a comparison with the calculated regurgitant volume derived from simultaneous measurement of total and forward stroke volumes has not been performed in human beings. Furthermore, whether the stroke index ratio improves after surgical correction of the regurgitant lesion remains to be determined. To explore these questions, we determined the stroke index ratio in a large series of patients with aortic and mitral regurgitation before and after valve replacement surgery.

Methods

Study patients: We evaluated 30 patients, whose clinical characteristics are shown in Table I. Twenty patients (10 men and 10 women, aged 23 to 72 years) had symptomatic aortic or mitral regurgitation; 18 patients in this group subsequently underwent valve replacement surgery within 1 week of angiographic evaluation. Ten patients (5 men and 5 women, aged 32 to 72 years) had cardiac catheterization for evaluation of coronary artery disease and did not have valve regurgitation, and thus served as control subjects. No patient had clinical or angiographic evidence of tricuspid regurgitation.

Calculation of the angiographic regurgitant volume and fraction: All 30 patients underwent cardiac catheterization utilizing the Sones technique. Left ventricular angiograms were performed in the right anterior oblique projection after retrograde catheterization of the left ventricle with a Sones or National Institutes of Health catheter introduced through the brachial artery. Regurgitant fraction was determined in 15 of the 20 patients with angiographically visualized aortic or mitral regurgitation. In these patients, left ventricular end-systolic and end-diastolic volumes were derived using the formula of Sandler and Dodge.[5] The total stroke volume was calculated as the difference between end-diastolic and end-systolic volumes and forward stroke volume was calculated by dividing the forward cardiac output (measured with the thermodilution technique) by the simultaneous determined heart rate. The regurgitant volume was calculated as the difference between total stroke and forward stroke volumes, and the regurgitant fraction was calculated by dividing the regurgitant volume by total stroke volume.

Calculation of the radionuclide stroke index ratio: Gated blood pool scans using technetium-99m labeled albumin (15 to 20 mCi) were performed in all 30 patients within 48 hours of cardiac catheterization. These were repeated in

* Regurgitant fraction not determined in these five patients.
† Valve replacement surgery not performed in these two patients.
AR = aortic regurgitation; BAV = bicuspid aortic valve; CAD = coronary artery disease; MR = mitral regurgitation; MVP = mitral valve prolapse; PMD = papillary muscle dysfunction; RCT = ruptured chordae tendineae; RHD = rheumatic heart disease. Numbers in parentheses refer to angiographic grade of regurgitation.

the 18 patients with valve regurgitation who had valve replacement surgery 7 to 10 days postoperatively. Acquisition was performed in the 40 to 45° left anterior oblique projection using an Ohio Nuclear sigma microprocessor 550 camera with an 18 parallel hole 1 inch (2.54 cm) thick collimator, acquiring a density of 256 counts/pixel in the left ventricle. For each patient, the angle of the projection was optimized for best separation of the left and right ventricles, but no caudal tilt was used. Data were recorded using a continuous electrocardiographically synchronized mode with 16 frames scanning the cardiac cycle. The total acquisition time was 7 to 8 minutes.

Regions of interest were drawn over the right and left ventricles and right and left atria. The regions of interest were defined by visual inspection and were fixed throughout the time course of systole and diastole. Background subtraction was not performed. The entire time-activity curve was displayed from each chamber to minimize atrioventricular overlap; diastolic and systolic periods were selected separately for each ventricle at the peak and nadir of each ventricular curve.

Derived variables were calculated as follows: (1) Ventricular stroke counts index = change in counts between systole and diastole in the ventricular region of interest. (2) Stroke index ratio = left ventricular stroke counts index/right ventricular stroke counts index.

Statistical analysis: The stroke index ratio before surgery in the 20 patients with valve regurgitation was compared with that of the 10 patients without regurgitation by means of the *t* test for independent variables. The regurgitant fraction determined during cardiac catheterization in 15 patients was tested for possible relation to the stroke index ratio determined from radionuclide angiocardiography by least squares linear regression analysis. Pre- and postoperative values for the stroke index ratio were compared in the 18 patients who had valve replacement surgery by means of the *t* test for paired data. Group data are expressed as mean values standard deviation.

Results

The stroke index ratio in the 20 patients with angi graphically demonstrated aortic or mitral regurgitatio or both (mean 3.91 ± 1.45, range 1.84 to 6.73) was si nificantly higher than that in the control group of patients without regurgitation (mean 1.32 ± 0.15, ran 0.99 to 1.49 ($p < 0.001$). In the 15 patients whose regu gitant fraction was calculated by simultaneous dete minations of total and forward stroke volumes duri cardiac catheterization, the stroke index ratio varie linearly and directly with the regurgitant fraction (r 0.947, $p < 0.001$) (Fig. 1).

Effect of valve replacement: After aortic and mitr valve replacement, the stroke index ratio decrease from 4.03 ± 1.46 to 1.38 ± 0.23 ($p < 0.001$, $n = 18$), value not significantly different from that observed our control patients without regurgitation (Fig. 2 Fifteen patients had no clinical evidence for residu valve regurgitation postoperatively and had strol index ratios of 1.03 to 1.49. Three patients had clinic evidence of regurgitation postoperatively; (in two p tients with aortic valve replacement a perivalve le

developed, and in one patient with severe aortic and mild mitral regurgitation preoperatively only the aortic valve was replaced). All three patients had a postoperative stroke index ratio (1.7 to 1.9) that was greater than 2 standard deviations above the mean values for our control group (>1.62).

The intraobserver agreement for determination of the stroke index ratio calculated from independent measurements made without knowledge of the catheterization data or the pre- or postoperative status of the images was excellent (r = 0.98).

Discussion

Our study validates the use of the stroke index ratio determined with radionuclide angiocardiography as an estimate of the magnitude of valve regurgitation in patients with aortic or mitral valve disease, or both. Preliminary studies[2,3] have previously shown a good relation between the stroke ratio index and qualitative estimates of angiographic regurgitation.[2,3] Our present data extend these findings and establish a linear relation between the index and quantitative calculations of the regurgitant fraction in man. Furthermore, our data indicate that the stroke index ratio is significantly reduced toward the normal range by surgical correction of the valve lesion. A stroke ratio index greater than 1.62 indicates significant valve regurgitation preoperatively and suggests residual regurgitation postoperatively.

Limitations of the method: Despite these encouraging results, the technique has major limitations in detecting and quantifying mild degrees of regurgitation. We and others[2,3] have found that the stroke index ratio in normal subjects was higher than the expected value of 1.0, so that the ratio in patients with mild degrees of regurgitation might occasionally fall into the normal range. Previous investigations[3] have established that this is most likely due to incomplete separation of the right and left ventricles from the surrounding structures, because in the left anterior oblique projection the atria are superimposed on a portion of the ventricular regions of interest, the degree of overlap being variable during different parts of the cardiac cycle. For this reason, in this study, only ratios greater than 1.62 exceeded 2 standard deviations above the mean value of our control group. This value (which corresponds to a regurgitant fraction of 22 percent (Fig. 1) represents the mildest degree of regurgitation that can be detected with certainty. It is similar to the 30 percent value suggested by Rigo et al.,[2] who used similar methods. However, use of a slant hole collimator with a 30° caudal tilt can reduce the degree of overlap and narrow the range for normal subjects for the stroke index ratio toward unity[3]; this would facilitate detection of smaller degrees of regurgitation. Further validation of this technique in patients with marked dilatation of atrial or ventricular chambers needs to be done.

Applications of the method: advantages over ejection fraction: The ability to estimate the magnitude of regurgitation substantially increases the value of radionuclide angiography in the evaluation of cardiac performance in a variety of cardiac disorders. Although the reliability of radionuclide studies in the measurement of ejection fraction is well established,[7] the ejection fraction frequently poorly reflects the hemodynamic and clinical characteristics of patients with significant regurgitant lesions. Whereas the ejection fraction correlates well with the hemodynamic and clinical results in patients who undergo coronary bypass surgery,[8,9] it often decreases after mitral valve replacement for valve regurgitation despite an improvement in forward output, reduction in pulmonary congestion and marked amelioration of dyspnea and fatigue.[10,11] Conversely, the ejection fraction may rise after the onset of acute mitral regurgitation secondary to a perivalve leak due to the creation of a low impedance leak,[12] despite severe hemodynamic and symptomatic deterioration. Furthermore, significant decreases in regurgitant volume may accompany the administration of peripheral vasodilators to patients with valve regurgitation, although changes in ejection fraction are frequently insignificant.[13–15] These reductions may explain in part why vasodilator therapy is often unaccompanied by changes in radionuclide ejection fraction despite hemodynamic and clinical improvement[13,16]; in such cases, estimation of the magnitude of regurgitation by the methods described in this study may reveal significant benefit not reflected by a consideration of ejection fraction alone.

In conclusion, radionuclide angiography provides a noninvasive method of detecting and quantifying the magnitude of left-sided valve regurgitation by the use of a method that compares left ventricular and right ventricular systolic and diastolic counts. This method has great potential clinical utility in the long-term follow-up of asymptomatic patients with mitral or aortic insufficiency, or both, and in the evaluation of the results of medical and surgical interventions.

The radionuclide regurgitant index, defined as left ventricular/right ventricular stroke counts obtained from gated equilibrium studies, has been reported to predict the presence and severity of left-sided valve regurgitation. This study evaluated the radionuclide regurgitant index in 100 patients in whom left-sided valve regurgitation was angiographically graded (0 to 4+) with regard to most severe mitral or aortic regurgitation. Regurgitation was graded 0 in 44 of the 100 patients, 1+ in 22, 2+ in 8, 3+ in 6 and 4+ in 20.

The radionuclide regurgitant index was 0.9 to 1.5 in 51 patients, 1.6 to 2.4 in 23 and 2.5 to 12.0 in 26. The mean radionuclide regurgitant index was 1.34 in the group with no regurgitation and 1.60 in those with 1+, 2.01 in those with 2+, 2.80 in those with 3+ and 3.85 in those with 4+ regurgitation. There was a significant difference ($p < 0.05$) in the radionuclide regurgitant index between patients with no regurgitation and each group with regurgitation and between groups with regurgitation separated by two or more grades of angiographic regurgitation.

Twelve patients had a discordant radionuclide regurgitant index; their index either predicted clinically significant or severe regurgitation when they had no or trivial regurgitation, or predicted no or trivial regurgitation when they had clinically significant regurgitation. Eight of 10 patients with a left ventricular ejection fraction of less than 0.30 had a discordant index ($p < 0.0005$). All three patients with mitral valve prolapse associated with frequent ventricular extrasystoles had a discordant index ($p < 0.0005$).

Recently, gated radionuclide equilibrium studies have been utilized as a noninvasive technique for measuring the severity of valve regurgitation. Rigo et al.[1] reported a radionuclide index of left-sided valve regurgitation derived from gated cardiac blood pool studies. This index was defined as the ratio of left to right ventricular stroke counts, calculated from the difference in counts in each ventricle between end-diastole and end-systole. On the basis of studies in 40 patients (31 with cardiac catheterization), they suggested that this index was useful in assessing the presence and severity of aortic or mitral regurgitation, or both.

In this study, we measured the radionuclide regurgitant index in 100 patients undergoing both cardiac catheterization and electrocardiographically synchronized radionuclide cardiac studies in an attempt to assess further the utility of this new noninvasive measure of left-sided valve regurgitation. In addition, we attempted to define subgroups of patients whose radionuclide regurgitant index appeared to predict spuriously the presence or absence of significant regurgitation.

Methods

Patient selection: The study group consisted of 100 consecutive patients undergoing clinically indicated diagnostic cardiac catheterization and radionuclide cardiac equilibrium studies. The catheterization and radionuclide studies were performed within a period of 2 weeks in all patients and within 3 days in 66 patients. There was no change in the clinical or hemodynamic status of any patient between the two studies. Patients were excluded from consideration and

were not included in this analysis if they had an intracardiac shunt or clinically evident tricuspid regurgitation.

Angiographic studies: The angiographic methods included biplane left cineventriculography (30° right anterior oblique and 60° left anterior oblique projections) in all patients, and ascending aortography (45° left anterior oblique projection) for aortic regurgitation when clinically indicated. The severity of mitral and aortic regurgitation was angiographically graded (only during conducted beats) by consensus of two of us on a 0 to 4+ scale modified from Sellers et al.[2] The grading scale was as follows: 0 = no regurgitation visualized; 1+ = slight opacification of the proximal chamber clearing completely in one cycle; 2+ = moderate opacification of the proximal chamber not completely clearing in one cycle but without progressive opacification; 3+ = progressive opacification of the proximal chamber over three or more cycles; 4+ = total opacification of the proximal chamber within one or two cycles.

For purposes of this study, patients with combined aortic and mitral regurgitation were categorized according to the most severe lesion. This categorization, rather than algebraic addition of graded aortic and mitral regurgitation, was utilized because the angiographic grading is not necessarily a linear function for which addition would be appropriate. For example, the severity of regurgitation in a patient with 2+ aortic and 2+ mitral regurgitation is not necessarily the same as that in a patient with a 4+ mitral regurgitation, and is of less clinical importance.

Radionuclide studies: The radionuclide cardiac studies were performed with 15 to 25 mCi of technetium-99m in vivo labeled red blood cells.[3] A large field of view Anger camera with a low energy all-purpose collimator was positioned in the left anterior oblique projection, chosen for best visualization of the ventricular septum, with a 10° to 15° caudal tilt. The electrocardiographically synchronized cardiac equilibrium study was acquired onto a dedicated mini-computer SIMIS-III (Informatek State, Inc., Norcross, Georgia), in 16 frames of 64 by 64 matrix resolution. Acquisition was continued until there were 500,000 counts/frame. Frame duration ranged from 30 to 60 ms depending on the patient's heart rate. The left ventricular ejection fraction was calculated in a standard manner previously described.[4]

For calculation of the regurgitant index, the end-diastolic frame was considered the first frame after the R wave. The end-systolic frame was taken from the nadir of the left ventricular time-activity curve derived during the calculation of ejection fraction. A region of interest for each ventricle in end-diastole (drawn by consensus of three of us) was utilized to calculate the regurgitant index. These regions of interest were drawn on simultaneously displayed end-diastolic and end-systolic frames, and on subtraction images (obtained from subtracting the end-systolic from the end-diastolic frame and vice versa) using a double cursor technique.[5] For the right ventricle, the subtraction images were particularly useful for delineating the right ventricular region of interest. In this way, the best delineation of the boundary between the right atrium and right ventricle was possible (Fig. 1). The left ventricular region of interest was actually obtained during the ejection fraction processing so that the determination of the regurgitant index added only a small amount to the overall processing time. *The regurgitant index was calculated by the following formula:*

$$\text{Regurgitant index} = \frac{\text{LV stroke counts}}{\text{RV stroke counts}},$$

where LV stroke counts = (counts in end-diastolic frame from left ventricular end-diastolic region of interest) minus (counts in end-systolic frame from left ventricular end-diastolic region of interest), and right ventricular stroke counts = (counts in end-diastolic frame from right ventricular end-diastolic region of interest) minus (counts in end-systolic frame from right ventricular end-diastolic region of interest).

FIGURE 1. Delineation of right and left ventricular regions of interest for calculation of the radionuclide regurgitant index is performed on simultaneously displayed end-diastolic (**a**), end-systolic (**b**) and subtraction images [end-diastole minus end-systole (**c**) and end-systole minus end-diastole (**d**)].

Thus, no background was subtracted in this calculation and the same end-diastolic and end-systolic frames were used for both ventricles. Also, only the end-diastolic regions of interest were utilized for counts from the ventricles in end-systole as well as end-diastole.

Statistical analysis: The calculation of the radionuclide regurgitant index and angiographic grading were performed independently. The radionuclide regurgitant index was compared with angiographically graded regurgitation using a logarithmic transformation and one way analysis of variance. The chi-square test with the Yates correction was utilized to compare patient subgroups.

Results

Patient characteristics: Of the 100 patients studied, 57 were male and 43 female; their ages ranged from 14 to 73 years (mean ± standard deviation 44.6 ± 16.3 years). Table I lists the cardiac diagnosis in these 100 patients. Ninety-four patients had sinus rhythm, including 16 patients who had frequent (6 or more/min) ventricular extrasystoles. Six patients had chronic atrial fibrillation.

TABLE I

Cardiac Diagnoses of Study Group

Diagnosis	Patients (n)
No structural heart disease	14
Coronary artery disease	25
Rheumatic heart disease	21
Primary myocardial disease	16
Mitral valve prolapse	11
Bacterial endocarditis	5
Other valvular heart disease	6
Other nonvalvular heart disease	2
Total	100

The left ventricular ejection fraction obtained from the radionuclide study ranged from 0.15 to 0.82 (mean 0.55 ± 0.16). Left ventricular ejection fraction was greater than 0.50 in 68 patients, between 0.30 and 0.50 in 22 patients and less than 0.30 in 10 patients.

Angiographic regurgitation: Angiography demonstrated no left-sided regurgitation in 44 patients, mitral regurgitation in 29, aortic regurgitation in 14 and both mitral and aortic regurgitation in 13 patients.

Among the 56 patients with regurgitation, the regurgitation was graded 1+ in 22, 2+ in 8, 3+ in 6 and 4+ in 20. The 56 patients included 4 patients with frequent ventricular extrasystoles (3 with 1+, 1 with 2+ regurgitation) and 3 patients with atrial fibrillation (1 with 1+, 1 with 2+ and 1 with 4+ regurgitation).

Radionuclide regurgitant index: For the entire study group, the radionuclide regurgitant index ranged from 0.9 to 12.0 (mean of 1.86; range encompassing mean ±1 SD 1.31 to 2.64). The regurgitant index ranged from 0.9 to 1.5 in 51 patients and from 1.6 to 2.4 in 23; it was 2.5 or greater in 26 patients.

Figure 2 presents the regurgitant index for all patients as a function of angiographically graded regurgitation. Table II lists the mean regurgitant index for each group of angiographically graded regurgitation.

There was a statistically significant difference ($p < 0.05$) between the regurgitant index of the group with no regurgitation and that of each group with regurgitation. In groups with regurgitation, the regurgitant index did not differ significantly between adjacent grades; however, there was a significant difference between groups separated by more than one grade (that is, 1+ versus 3+ or 4+, and 2+ versus 4+).

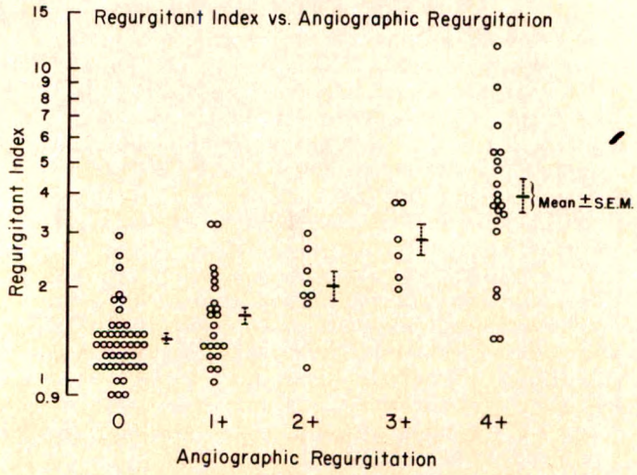

FIGURE 2. The radionuclide regurgitant index (on a logarithmic scale) is compared with the grade of angiographic regurgitation. Each patient is represented by an **open circle. Bar markers** indicate the mean and standard error of the mean (S.E.M.) for each angiographic grade. See text for discussion.

Predictive accuracy of the regurgitant index: Table III demonstrates the ability of a regurgitant index of 1.5 or less to predict no or trivial regurgitation (0 or 1+), and a regurgitant index of greater than 1.5 to predict the presence of clinically significant regurgitation (2+, 3+ or 4+).

Ninety-four percent (48 of 51) of patients with a regurgitant index of 1.5 or less had no or trivial regurgitation; 37 percent (18 of 49) of patients with a regurgitant index greater than 1.5 had no or trivial regurgitation, and 63 percent (31 of 49) had significant regurgitation. Conversely, 73 percent (48 of 66) of patients with no or trivial regurgitation had a regurgitant index of 1.5 or less (chi-square = 34, $p < 0.0005$). Thus, a regurgitant index of 1.5 or less is a very specific (94 percent) but less sensitive (73 percent) indicator for detecting the absence of significant regurgitation.

TABLE II

Radionuclide Regurgitant Indexes in Each Grade of Angiographic Regurgitation

Angiographic Grade	Radionuclide Regurgitant Indexes			
	Range	Mean	Mean ±1 SD	Mean ±1 SEM
0	0.9–2.9	1.34	1.04–1.71	1.29–1.39
1+	1.0–3.2	1.60	1.16–2.21	1.50–1.72
2+	1.1–3.0	2.01	1.49–2.72	1.81–2.24
3+	2.0–3.8	2.80	2.13–3.67	2.51–3.13
4+	1.4–12.0	3.85	2.22–6.65	3.41–4.35

SD = standard deviation; SEM = standard error of the mean.

TABLE III

Predictive Value of the Radionuclide Regurgitant Index for Clinically Significant and Severe Regurgitation

Radionuclide Regurgitant Index	Patients With No or Trivial (0, 1+) Regurgitation (n)	Patients With Significant (2+, 3+, 4+) Regurgitation (n)	Total
≤1.5	48	3	51
>1.5	18	31	49
Total	66	34	100
	Patients With Nonsevere (0, 1+, 2+) Regurgitation (n)	Patients With Severe (3+, 4+) Regurgitation (n)	
<2.5	68	6	74
≥2.5	6	20	26
Total	74	26	100

Table III demonstrates the ability of a regurgitant index of 2.5 or greater to predict the presence of clinically severe regurgitation (3+ or 4+) and a regurgitant index of less than 2.5 to predict the absence of severe regurgitation (0, 1+ or 2+).

Seventy-seven percent (20 of 26) of patients with a regurgitant index of 2.5 or greater had severe regurgitation; 92 percent (68 of 74) of patients with a regurgitant index of less than 2.5 did not have severe regurgitation. Conversely, 77 percent (20 of 26) of patients with severe regurgitation had a regurgitant index of 2.5 or greater (chi-square = 45, $p < 0.0005$). Thus, a regurgitant index of 2.5 or greater was a relatively sensitive (77 percent) and specific (77 percent) indicator of severe regurgitation.

Clinical characteristics of patients with a discordant regurgitant index: The regurgitant index was arbitrarily defined as discordant if it was greater than 1.5 in patients with no regurgitation or greater than 2.5 in patients with 1+ regurgitation (Fig. 3). In patients with 2+, 3+ and 4+ regurgitation, the regurgitant index was also arbitrarily defined as discordant if it was 1.5 or less.

Twelve patients had a discordant regurgitant index. Nine of these had false positive discordance (that is, a regurgitant index predicting significant or severe regurgitation in patients with no or trivial regurgitation). Three of these nine patients had both mitral valve prolapse and frequent ventricular extrasystoles, five had a left ventricular ejection fraction of less than 0.30, and one had coronary artery disease with an ejection fraction of 0.47.

Three patients had false negative discordance (that is, a regurgitant index predicting no or trivial regurgitation in patients with significant regurgitation). All three had a left ventricular ejection fraction of less than 0.30.

Table IV presents the incidence of discordance in specific patient groups. There was a significant association of discordance with a left ventricular ejection fraction of less than 0.30 and with mitral valve prolapse associated with frequent ventricular extrasystoles. Patients with frequent ventricular extrasystoles alone (without an ejection fraction of less than 0.30 or mitral valve prolapse), atrial fibrillation or mitral valve prolapse without frequent ventricular extrasystoles did not have a discordant regurgitant index.

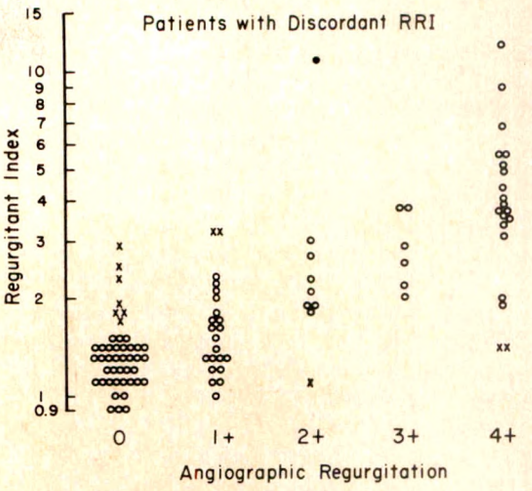

FIGURE 3. The radionuclide regurgitant index (RRI) is compared with the grade of angiographic regurgitation as in Figure 2. Patients with a regurgitant index considered discordant (see text for discussion) are represented by **crosses.** The remaining patients, whose regurgitant index was not discordant, are represented by **open circles.**

Discussion

Gated cardiac blood pool studies have previously been validated for the noninvasive evaluation of right and left ventricular function.[6–10] These studies have been demonstrated to be useful for measuring ventricular ejection fraction and assessing regional wall motion abnormalities. Recently, Rigo et al.[1] proposed the ratio of left to right ventricular stroke counts (defined as the difference between end-diastolic and end-systolic counts for each ventricle) as a measurement of the presence and severity of left-sided valve regurgitation. In their patients with significant mitral or aortic regurgitation, or both, the ratio of left to right ventricular stroke counts was significantly greater than unity. In their patients without regurgitation, this ratio ranged from 0.9 to 1.4 (mean 1.15). Baxter et al.[11] provided quantitative verification of this hypothesis utilizing a dog model with experimentally induced acute aortic regurgitation. Bough et al.[12] recently reported reasonable correlation of this stroke count ratio with quantitative catheterization methods.

Rigo et al.[1] demonstrated that this ratio of left to right ventricular stroke counts, or regurgitant index, was

TABLE IV

Incidence of Discordant Radionuclide Regurgitant Indexes

	Patients in Total Series (n)	Patients With Index Discordant		p Value*
		n	%	
Entire study group	100	12	12	
Ejection fraction <0.30	10	8	80	<0.0005
Mitral prolapse without PVCs	8	0	0	NS
PVCs without mitral prolapse	13	2†	15	NS
Mitral prolapse with PVCs	3	3	100	<0.0005
Atrial fibrillation	6	0	0	NS

* Probability (p) value of chi-square test comparing presence of discordance and presence or absence of clinical characteristic listed.
† Two patients with PVCs without mitral prolapse with a discordant regurgitant index had an ejection fraction of less than 0.30.
NS = not significant; PVCs = frequent ventricular contractions.

reproducible when calculated by different observers. Because we also have found little interobserver variability in calculation of the radionuclide regurgitant index, we did not formally repeat this study. Rigo et al. showed a significant correlation between the regurgitant index and the severity of left-sided valve regurgitation in 40 patients (of whom 31 underwent catheterization and 20 manifested regurgitation of varying degrees of severity). There was no overlap in the regurgitant indexes calculated in patients with no regurgitation and in those with moderate or severe regurgitation. The patients studied had good overall left ventricular function, only four having a reduced left ventricular ejection fraction (less than 0.50).

Methodologic considerations: In this study, we attempted to assess the usefulness of the radionuclide regurgitant index in a variety of cardiac disorders, rhythms and ranges of cardiac function. Our radionuclide method was based on the principle outlined by Rigo et al.[1] utilizing a single end-diastolic region of interest for each ventricle without background subtraction. Our technique differed from that of Rigo et al. because we used (1) in vivo labeled red blood cells rather than labeled albumin[3]; (2) a caudal tilt in the left anterior oblique position; (3) subtraction images (including end-diastole minus end-systole and end-systole minus end-diastole)[5,8,9]; and (4) the continuous electrocardiographically synchronized equilibrium mode of acquisition for all studies.[4] The use of the caudal tilt allowed improved separation of the atria from the ventricles, especially in the right side of the heart. Subtraction images, especially the "stroke volume image" (obtained from the subtraction of end-systole from end-diastole), aided in the delineation of the right and left ventricular regions of interest. The radionuclide methods we utilized are virtually identical to the methods used in the recent report of Bough et al.[12] However, Bough et al. utilized a 30° caudal slant hole collimator of intermediate sensitivity as opposed to a caudal tilt.

We applied the continuous electrocardiographically synchronized mode of acquisition and display to all patients studied. Rigo et al.[1] applied this mode of display in only 19 of 40 patients. For simplicity, we utilized only the nadir of the left ventricular time-activity curve in identifying the end-systolic frame for both ventricles. Although there is a potential for error because right and left ventricular end-systole may not coincide, Rigo et al. found no systematic difference between using the same end-systolic frame for both ventricles as opposed to using separate time-activity curves to identify each ventricular end-systole.

In our method, the cardiac cycle was divided into 16 frames. Theoretically, increasing the number of frames would appear to increase the accuracy of the regurgitant index because the peak and nadir of time-activity curves would be sharper. However, to obtain the same number of overall counts/frame, a longer acquisition time would be necessary because the time interval of each frame would be shorter. Otherwise, for the same acquisition time, increasing the number of frames would result in a lower number of counts/frame and more statistical variation.

Correlation of radionuclide and angiographic regurgitation: In our series, the radionuclide regurgitant index generally correlated with the presence and severity of angiographic left-sided valve regurgitation. There was a significant difference between the regurgitant index of patients without angiographic regurgitation and that of patients with 1+ or greater regurgitation. There was no significant difference between the indexes of patients with adjacent angiographic grades of regurgitation, a finding that may reflect the small number of patients with angiographically graded 2+ and 3+ regurgitation. Comparison of the regurgitant indexes of patients separated by more than one grade of regurgitation (that is, 1+ versus 3+, 2+ versus 4+) showed a significant difference.

A regurgitant index of 1.5 or less generally indicated no or trivial regurgitation. This separation was more specific (94 percent) than it was sensitive (73 percent). A regurgitant index of 2.5 or greater was a relatively sensitive (77 percent) and specific (77 percent) predictor of severe regurgitation. Patients with a regurgitant index between 1.5 and 2.4 had a wide range of angiographic regurgitation. Generally, they had 0, 1+ or 2+ regurgitation rather than 3+ or 4+ regurgitation, but this trend did not appear to be of statistical significance.

Causes of discrepancies between angiographic grading and regurgitant index: Unlike the patients studied by Rigo et al.,[1] our patients demonstrated some overlap in the range of regurgitant indexes in all angiographic grades of regurgitation. The study by Bough et al.[12] illustrated some discrepancies between the angiographic grading and the radionuclide assessment of the severity of valve regurgitation; however, there was no explanation of these discrepancies. In attempting to identify the characteristics of patients whose regurgitant index appeared to be obviously discordant, we examined a group of arbitrarily classified patients on the basis of regurgitant indexes shown to separate no and trivial from significant regurgitation, and severe from nonsevere regurgitation. Patients with a greatly reduced left ventricular ejection fraction (less than 0.30) had a significantly greater incidence of discordance than did patients with an ejection fraction of 0.30 or greater. We can only postulate why the regurgitant index appears to predict inaccurately the presence or severity of regurgitation in patients with a greatly decreased left ventricular ejection fraction. Such patients generally have elevated pulmonary arterial pressures or right ventricular failure and may have clinically silent tricuspid regurgitation. These conditions would tend to reduce the radionuclide regurgitant index in patients with significant left-sided regurgitation. Conversely, the severity of regurgitation may be overestimated angiographically in these patients because of a relatively slow washout of contrast medium with a greatly reduced forward output. These explanations would not account for the discrepancies noted in patients with a low ejection fraction, no angiographic regurgitation and a high

regurgitant index. The precision with which the stroke counts can be measured may be reduced in patients with low right and left ventricular ejection fractions and markedly dilated ventricular chambers. This factor may account for these discrepancies.

Limitations of method and sources of error: The inability of the radionuclide regurgitant index to detect the presence of severity of regurgitation in patients with a very low ejection fraction limits its usefulness in assessing the significance of a mitral regurgitant murmur in these patients. Thus, the regurgitant index would not be able to discriminate adequately between a patient with a cardiomyopathy with mild mitral regurgitation (secondary to distortion of the supporting structures of the mitral valve) and a patient with severe long-standing mitral regurgitation with resultant depressed left ventricular dysfunction (secondary to the volume overload) if the ejection fraction was less than 0.30.

All three patients with mitral valve prolapse associated with frequent ventricular extrasystoles had a high regurgitant index in the absence of angiographic mitral regurgitation during conducted beats. There were eight patients with mitral valve prolapse alone and 11 patients with frequent ventricular extrasystoles alone (without either prolapse or a greatly reduced ventricular ejection fraction). None of these patients had a discordant regurgitant index. Possibly, the patients with both mitral valve prolapse and frequent ventricular extrasystoles had mitral regurgitation with extrasystoles during the radionuclide study that was not noted during angiography (when only conducted beats were analyzed). The presence of atrial fibrillation did not invalidate the regurgitant index.

This radionuclide method is also theoretically limited in clinical conditions with volume overload of the right ventricle such as tricuspid regurgitation or atrial septal defect. Also, the method does not allow discrimination of aortic from mitral regurgitation.

Previous angiographic studies have demonstrated nearly equal right and left ventricular stroke volumes in the absence of shunts and valve regurgitation.[13] It was not immediately clear why the regurgitant index was greater than 1.0 in some patients with no regurgitation. It is more difficult to separate the right atrium from the right ventricle than it is to separate the left atrium from the left ventricle in the radionuclide study. Because the right atrial time-activity curve peaks during right ventricular systole, inclusion of a portion of the right atrium in the right ventricular region of interest would result in a dampening of the right ventricular time-activity curve. This reduction in the right ventricular stroke counts would systematically increase the ratio of left to right ventricular stroke counts.

There may be other geometric factors that may resul in different absorption characteristics of each ventric ular blood pool. Reported data[12,14] suggest that bette separation of the atria from the ventricles with a 30 slant hole collimator results in regurgitant indexes close to unity and with less variability (1.00 ± 0.08) in pa tients with no regurgitation. We were able to obtain onl a 10° to 15° caudal angulation, a factor that might ex plain our higher values. Our mean value for regurgitan index (1.34) was also higher than that (1.15) reporte by Rigo et al. for patients with no regurgitation. Ou method utilized a 10° to 15° caudal tilt, whereas Rig et al. did not utilize any caudal tilt. Thus, the caudal til would not appear to explain the difference in this in stance. Our inclusion of patients with a wider range c cardiac function (including patients with a discordan index and a low ejection fraction) than that of patient in the study by Rigo and co-workers may explain th difference.

Limitations of angiographically graded re gurgitation: Unfortunately there is no ideal "gol standard" for the quantitation of valve regurgitation Angiographically graded regurgitation is the metho most widely utilized clinically. This visual grading c angiographic regurgitation is affected by the size of th ventricular and atrial chambers. Regurgitant fraction can be calculated by comparing the angiographic le ventricular stroke volume with the forward stroke vo ume calculated from the cardiac output and heart rat The presence of any arrhythmia during angiograph invalidates this calculation because only a few beats ar available for analysis. The angiographically calculate regurgitant fraction also is subject to the limitations c calculating the stroke volumes with angiography an with cardiac output determinations. This limitation a particular problem in patients with a very low cardia output and stroke volume and large ventricular vo umes. Limiting analysis to patients in whom a mea surement of an angiographic regurgitant fraction wa possible or whose regurgitant index corresponded to th angiographic grading would preselect patients and thu might lead to false conclusions of the accuracy of th radionuclide regurgitant index.

Implications: The radionuclide regurgitant index useful for assessing the presence and severity of lef sided valve regurgitation. The presence of a marked reduced left ventricular ejection fraction may result both false positive and false negative discordan regurgitant indexes. Mitral valve prolapse associate with frequent ventricular extrasystoles may result in false positive discordant regurgitant index. Recognizin these potential sources of error should make the r dionuclide regurgitant index more useful.

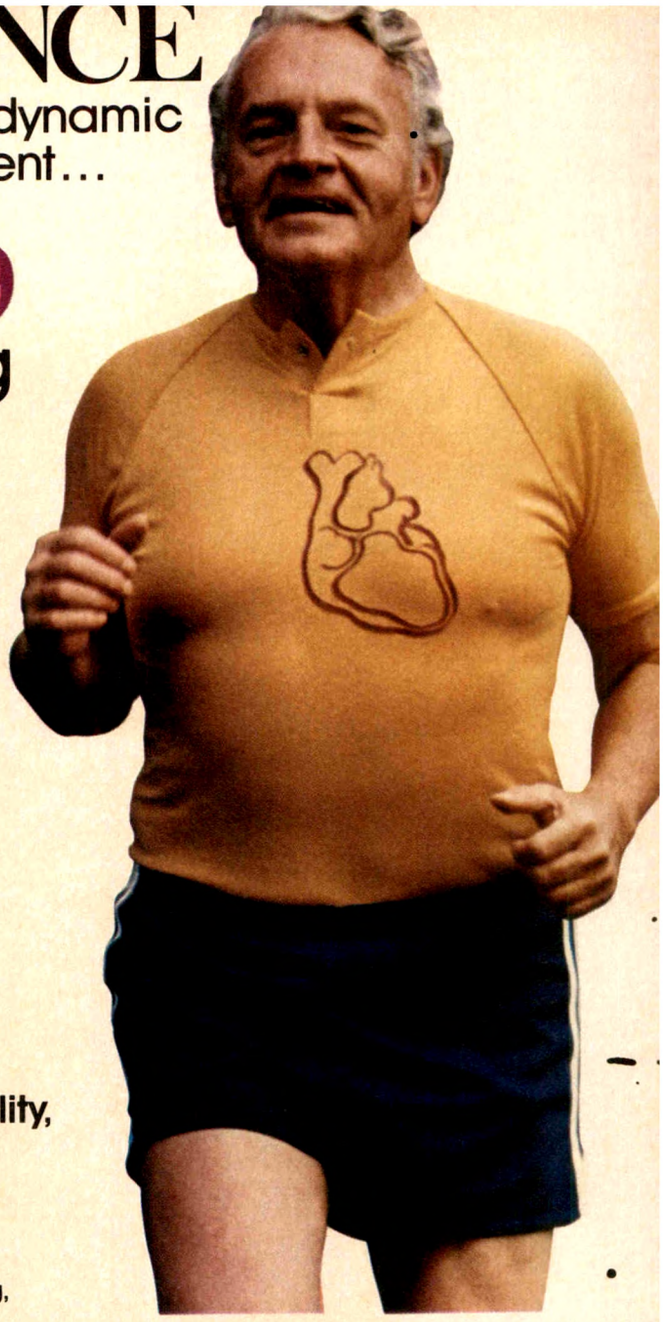
PERFORMANCE

for assured prolonged hemodynamic response in the angina* patient...

NITRO-BID® 9
(nitroglycerin) 9 mg
Capsules



Higher nitrate doses are often needed to achieve the desired clinical response in angina pectoris. Consider the benefits of NITRO-BID® 9 therapy:

- High-potency nitroglycerin
- Prolonged physiologic activity
- Convenient dosage regimens
- Aids patient compliance (b.i.d. or t.i.d. dosage)

For titration and dosage flexibility, also available as 6.5-mg and 2.5-mg strengths

NITRO-BID® (nitroglycerin) Plateau CAPS® 9 mg, 6.5 mg, and 2.5 mg

DESCRIPTION: Each NITRO-BID® Controlled-Release Capsule contains:

2.5 mg nitroglycerin: Light purple and clear capsule with white beads; identification imprint MARION/1550.

6.5 mg nitroglycerin: Dark blue and yellow capsule with white beads; identification imprint MARION/1551.

9 mg nitroglycerin: Green and yellow capsule with white beads; identification imprint MARION/1553.

ACTION: The mechanism of action of nitroglycerin in the relief of angina pectoris is not as yet known. However, its main pharmacologic action is to relax smooth muscle, principally in the smaller blood vessels, thus dilating arterioles and capillaries, especially in the coronary circulation. In therapeutic doses, nitroglycerin is thought to increase the blood supply to the myocardium which may, in turn, relieve myocardial ischemia, the possible functional basis for the pain of angina pectoris. The sublingual administration of nitroglycerin is normally rapid and transient, but nitroglycerin in controlled-release NITRO-BID® 2.5, NITRO-BID® 6.5, and NITRO-BID® 9 produces a prolonged action.

* **INDICATIONS:** Based on a review of this drug and a related drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

"Possibly" effective: For the management, prophylaxis or treatment of anginal attacks. Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS: Acute or recent myocardial infarction, severe anemia, closed-angle glaucoma, postural hypotension, increased intracranial pressure, and idiosyncrasy to the drug.

WARNINGS: Capsules must be swallowed. FOR ORAL, NOT SUBLINGUAL, USE. NITRO-BID 2.5, NITRO-BID® 6.5, and NITRO-BID® 9 Controlled-Release Capsules are not intended f immediate relief of anginal attacks.

PRECAUTIONS: Intraocular pressure may be increased; therefore, caution is required administering to patients with glaucoma. Tolerance to this drug and cross-tolerance other organic nitrites and nitrates may occur. If blurring of vision, dryness of mouth, lack of benefit occurs, the drug should be discontinued.

ADVERSE REACTIONS: Severe and persistent headaches, cutaneous flushing, dizzine and weakness. Occasionally, drug rash or exfoliative dermatitis and nausea and vomitin may occur; these responses may disappear with a decrease in dosage. Adverse effec are enhanced by ingestion of alcohol, which appears to increase absorption from th gastrointestinal tract.

DOSAGE AND ADMINISTRATION: Administer the smallest effective dose two or thre times daily at 8- to 12-hour intervals, unless clinical response suggests a differe regimen. Patient should be titrated to anginal relief or hemodynamic response. Hemo dynamic response can be measured by drop in systolic blood pressure. Discontinue not effective.

HOW SUPPLIED: NITRO-BID® 2.5 Controlled-Release Capsules and NITRO-BID® 6.5 Cor trolled-Release Capsules are each available in 60- and 100-count UNI-Rx® Paks and bottles of 60 and 100. NITRO-BID® 9 Controlled-Release Capsules are available 60-count bottles.

CAUTION: Federal law prohibits dispensing without prescriptio

THE NEW MICROTHIN™-P2... GUARANTEED SENSING

MICROTHIN-P2's sensing is so exceptional that, whenever you implant a MICROTHIN-P2 with a CPI® Porous Tip Lead, it is guaranteed. If any sensing difficulties develop, you'll receive immediate full credit for the MICROTHIN-P2.

CPI has recognized that efficient sensing is of paramount importance, and we've responded to that need with the MICROTHIN-P2. In fact, MICROTHIN-P2 addresses *all* the issues that are of prime importance in cardiac pacing:

- Proven reliability*
- The most useful programmable features - rate and energy output
- Superior sensing
- Lifetime warranty**
- Small size for patient comfort
- Easy, safe follow-up

Eight years of CPI experience prove that pacing can evolve... advance...become simpler yet superior. That's MICROTHIN-P2. It is the simple, effective solution for the majority of your pacemaker patients.

For single-rate demand pacing, ask your sales representative about MICROTHIN-D2.

*For a copy of CPI's "Seven Years of Reliability" report, contact your sales representative.

**The lifetime warranty option is not available in all countries. Contact your sales representative for full warranty information for your area.

SLOW-K®
potassium chloride slow-release tablets

DESCRIPTION
Slow-K is a sugar-coated (not enteric-coated) tablet containing 600 mg potassium chloride (equivalent to 8 mEq) in a wax matrix. This formulation is intended to provide a controlled release of potassium from the matrix to minimize the likelihood of producing high localized concentrations of potassium within the gastrointestinal tract.

INDICATIONS
BECAUSE OF REPORTS OF INTESTINAL AND GASTRIC ULCERATION AND BLEEDING WITH SLOW-RELEASE POTASSIUM CHLORIDE PREPARATIONS, THESE DRUGS SHOULD BE RESERVED FOR THOSE PATIENTS WHO CANNOT TOLERATE OR REFUSE TO TAKE LIQUID OR EFFERVESCENT POTASSIUM PREPARATIONS OR FOR PATIENTS IN WHOM THERE IS A PROBLEM OF COMPLIANCE WITH THESE PREPARATIONS.

1. For therapeutic use in patients with hypokalemia with or without metabolic alkalosis; in digitalis intoxication and in patients with hypokalemic familial periodic paralysis.

2. For prevention of potassium depletion when the dietary intake of potassium is inadequate in the following conditions: Patients receiving digitalis and diuretics for congestive heart failure; hepatic cirrhosis with ascites; states of aldosterone excess with normal renal function; potassium-losing nephropathy, and certain diarrheal states.

3. The use of potassium salts in patients receiving diuretics for uncomplicated essential hypertension is often unnecessary when such patients have a normal dietary pattern. Serum potassium should be checked periodically, however, and, if hypokalemia occurs, dietary supplementation with potassium-containing foods may be adequate to control milder cases. In more severe cases supplementation with potassium salts may be indicated.

CONTRAINDICATIONS
In patients with hyperkalemia, since a further increase in serum potassium concentration in such patients can produce cardiac arrest. Hyperkalemia may complicate any of the following conditions: chronic renal failure, systemic acidosis such as diabetic acidosis, acute dehydration, extensive tissue breakdown as in severe burns, adrenal insufficiency, or the administration of a potassium-sparing diuretic (*eg*, spironolactone, triamterene).

Wax-matrix potassium chloride preparations have produced esophageal ulceration in certain cardiac patients with esophageal compression due to enlarged left atrium.

All solid dosage forms of potassium supplements are contraindicated in any patient in whom there is cause for arrest or delay in tablet passage through the G.I. tract. In these instances, potassium supplementation should be with a liquid preparation.

WARNINGS
Hyperkalemia: In patients with impaired mechanisms for excreting potassium, administration of potassium salts can produce hyperkalemia and cardiac arrest. This occurs most commonly in patients given potassium intravenously but may also occur when given orally. Potentially fatal hyperkalemia can develop rapidly and be asymptomatic. Use of potassium salts in patients with chronic renal disease, or any other condition which impairs potassium excretion, requires particularly careful monitoring of the serum potassium concentration and appropriate dosage adjustment.

Interaction with Potassium-Sparing Diuretics: Hypokalemia should not be treated by the concomitant administration of potassium salts and a potassium-sparing diuretic (*eg*, spironolactone or triamterene), since the simultaneous administration of these agents can produce severe hyperkalemia.

Gastrointestinal lesions: Potassium chloride tablets have produced stenotic and/or ulcerative lesions of the small bowel and deaths. These lesions are caused by a high localized concentration of potassium ion in the region of a rapidly dissolving tablet, which injures the bowel wall and thereby produces obstruction, hemorrhage, or perforation. Slow-K is a wax-matrix tablet formulated to provide a controlled rate of release of potassium chloride and thus to minimize the possibility of a high local concentration of potassium ion near the bowel wall. While the reported frequency of small-bowel lesions is much less with wax-matrix tablets (less than one per 100,000 patient-years) than with enteric-coated potassium chloride tablets (40-50 per 100,000 patient-years) cases associated with wax-matrix tablets have been reported both in foreign countries and in the United States. In addition, perhaps because the wax-matrix preparations are not enteric-coated and release potassium in the stomach, there have been reports of upper gastrointestinal bleeding associated with these products. The total number of gastrointestinal lesions remains less than one per 100,000 patient-years. Slow-K should be discontinued immediately and the possibility of bowel obstruction or perforation considered if severe vomiting, abdominal pain, distention, or gastrointestinal bleeding occurs.

Metabolic acidosis: Hypokalemia in patients with metabolic *acidosis* should be treated with an alkalinizing potassium salt such as potassium bicarbonate, potassium citrate, or potassium acetate.

PRECAUTIONS
Potassium depletion is ordinarily diagnosed by demonstrating hypokalemia in a patient with a clinical history suggesting some cause for potassium depletion. In interpreting the serum potassium level, the physician should bear in mind that acute alkalosis *per se* can produce hypokalemia in the absence of a deficit in total body potassium, while acute acidosis *per se* can increase the serum potassium concentration into the normal range even in the presence of a reduced total body potassium. Treatment of potassium depletion, particularly in presence of cardiac disease, renal disease, or acidosis, requires careful attention to acid-base balance and appropriate monitoring of serum electrolytes, electrocardiogram, and clinical status of patient.

ADVERSE REACTIONS
Most common to oral potassium salts: nausea, vomiting, abdominal discomfort, and diarrhea. These symptoms are due to irritation of the gastrointestinal tract and are best managed by diluting the preparation further, taking the dose with meals, or reducing the dose.

One of the most severe adverse effects is hyperkalemia (see Contraindications and Warnings). There also have been reports of upper and lower gastrointestinal conditions including obstruction, bleeding, ulceration and perforation (see Contraindications and Warnings); other factors known to be associated with such conditions were present in many of these patients. Skin rash has been reported rarely.

DOSAGE AND ADMINISTRATION
Usual dietary intake of potassium by the average adult is 40 to 80 mEq per day. Potassium depletion sufficient to cause hypokalemia usually requires loss of 200 or more mEq of potassium from the total body store.

Dosage must be adjusted to the individual needs of each patient but is typically in the range of 20 mEq per day for prevention of hypokalemia to 40-100 mEq per day or more for treatment of potassium depletion.

Note: Slow-K slow-release tablets must be swallowed whole and never crushed or chewed.

Intermedics Pulse Generators

INDICATIONS AND CONTRAINDICATIONS

The indications for cardiac pacemaking are increasing as pacemakers become more sophisticated and as advanced methods for patient management become more widespread. Generally accepted indications for long-term cardiac pacing include but are not limited to: (1) sick sinus syndrome; (2) chronic, symptomatic drug-resistant sinus arrhythmias, including sinus bradycardia, sinus arrest, and sinoatrial (S-A) block as seen in sick sinus syndrome; (3) chronic, symptomatic second-degree or third-degree A-V block; (4) recurrent Adams-Stokes syndrome; (5) bradycardia-tachycardia syndrome; (6) symptomatic bilateral bundle branch block; and (7) hypersensitive carotid sinus syndrome (carotid sinus syncope). In addition, certain patients presenting with intractable, recurrent, congestive heart failure; cerebral or renal insufficiency; or recurrent, drug-resistant tachyarrhythmias who have been shown to benefit from temporary cardiac pacing are considered candidates for permanent cardiac pacemaking.

The indications for permanent pacing in the presence of acute myocardial infarction have not yet been rigorously defined. Factors to be considered include the location of the myocardial infarct, the presence or absence of symptoms, ventricular rate, mechanism of the arrhythmias, and response to therapy. In general, symptomatic drug-resistant bradyarrhythmias which impair cardiac output are considered indications for pacing in patients with acute myocardial infarction, regardless of infarct location.

There are no known contraindications to the use of pacemakers as a medical method for control of heart rate. However, body rejection phenomena such as local tissue reaction or skin necrosis, muscle and nerve stimulation, embolism, and cardiac tamponade have been reported.

CAUTION: Federal (U.S.A.) law restricts this device to sale by or on the order of a physician.

NOTE: The CyberLith and the CyberLith Programmer are currently undergoing clinical evaluation.

Intermedics Inc.
Our business is life.™

The CyberLith programming system.

Reliable, safe, convenient. And available.

CyberLith... the most sophisticated programming system ever.

Reliable

The CyberLith all electronic programming system assures reliability by eliminating phantom or cross-programming. The use of accurate crystal oscillators ensures precision transmission of programming information.

Safe

The CyberLith programming safety features help avoid unnecessary cardiac rhythm disturbances. Further, it is not necessary to place the pulse generator in the asynchronous mode during the programming session. The safety features also allow automatic error identification, preventing transmission of incompatible programming commands.

Convenient

The CyberLith programming system is fast — all five parameters are programmed within 40 milliseconds.

Available

CyberLith pacing systems are available now! Pulse generators, programmers, leads, telemetry equipment, and patient transmitters and receivers.

As the pioneers of multi-parameter programmable pacing technology, Intermedics has maintained its role as the manufacturer of the most advanced systems. Our commitment is to keep in pace with your desire for excellenc pacing therapy.

The CyberLith system is today's state-of-the-art. Get to know it. Fo more detailed information call or v the Intermedics marketing departr or contact your local Intermedics representative.

Now in book form...the latest **Update Your Medicine** lectures

CORNELL MEDICAL UPDATE/2

Edited by LILA A. WALLIS, MD, FACP

Helps you keep up with the new advances in your specialty in the comfort of your home or office.

All new material—specialties expanded.

The workbook format of CORNELL MEDICAL UPDATE/2 breaks medical publishing traditions by giving practicing physicians a quick overview of the latest advances in their specialty. It transcribes the Update Your Medicine lectures sponsored by New York Hospital-Cornell Medical Center. These lectures are well-known for helping physicians prepare for Recertification despite the demands of a heavy practice.

The new approach of the first volume was so well-received that it went through three printings in less than two years. Now the just published CORNELL MEDICAL UPDATE/2 takes up where the first volume left off. It has been specially designed for the practicing physician who has difficulty keeping up with the growing literature of the field. Each chapter transcribes one of the lectures and covers a specific speciality in-depth from basic physiologic and chemical principles to its clinical applications.

Lila A. Wallis, MD, FACP, the series editor, has eliminated all the filler material a *continuing* education does not need. You won't find historical reviews or a rehash of material you've known since medical school. You will find the practical, life-saving knowledge a dynamic practice depends on. Because the lectures have been edited for easy reading and laid out for quick comprehension, you'll be able to incorporate all the material into your own professional technique.

Earn 25 Credits Towards AMA Physician's Recognition Award. CORNELL MEDICAL UPDATE/2 has been approved for Category 1 credit towards the AMA's Physician's Recognition Award for Continuing Medical Education. Full details on how to apply for credit are included with every copy.

Yorke Medical Books, 666 5th Ave., N.Y., N.Y. 10103 AJC 2/81

Please send me a copy of CORNELL MEDICAL UPDATE/2 at $38.00. I may use the book for 30 days and if not completely satisfied, return it for full refund or credit.

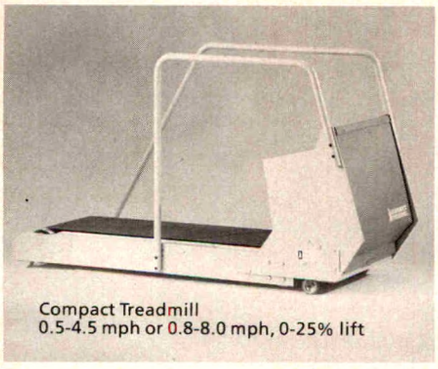
He might be running for his life

Whether he's in a cardiac conditioning, diagnostic or rehabilitation program, your patient deserves the best i exercise equipment. At Collins, we've been making the best for sixty years. From our first treadmill to our newes Pedalmate ergometer, each product has been developed to meet the Collins standard of excellence — innovativ design, durable construction and easy operation.

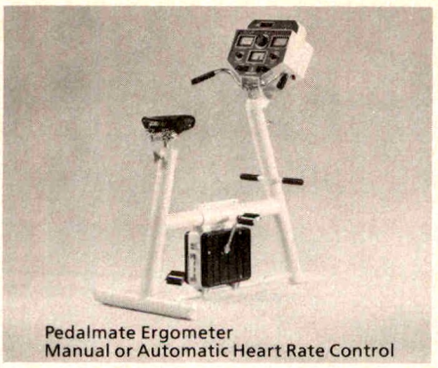
The result has been a continuing tradition of superior instruments that reflect not only the latest technology, but concern for patient comfort and safety as well. Each treadmill features handrails, a large usable walking area and new fiberglass fabric-coated surface under the belt to minimize friction and wear. Our four treadmills offer spee ranges up to 16 mph and electric lift from 0-40%. For precise manual or automatic heart rate control capabilities the Pedalmate combines the convenience of an exercise bicycle with the choice of either a 25-200 or 50-400 wat brake unit.

High quality plus performance — it all adds up to product integrity that has made Collins the first choice for over half a century. So when you need exercise equipment, choose Collins. You'll be sure of the best for your patient — and yourself. Write today for our latest catalog.

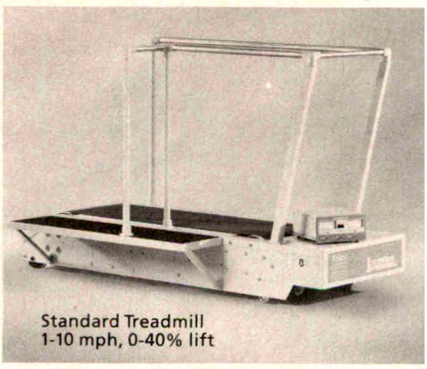
Collins



Compact Treadmill
0.5-4.5 mph or 0.8-8.0 mph, 0-25% lift

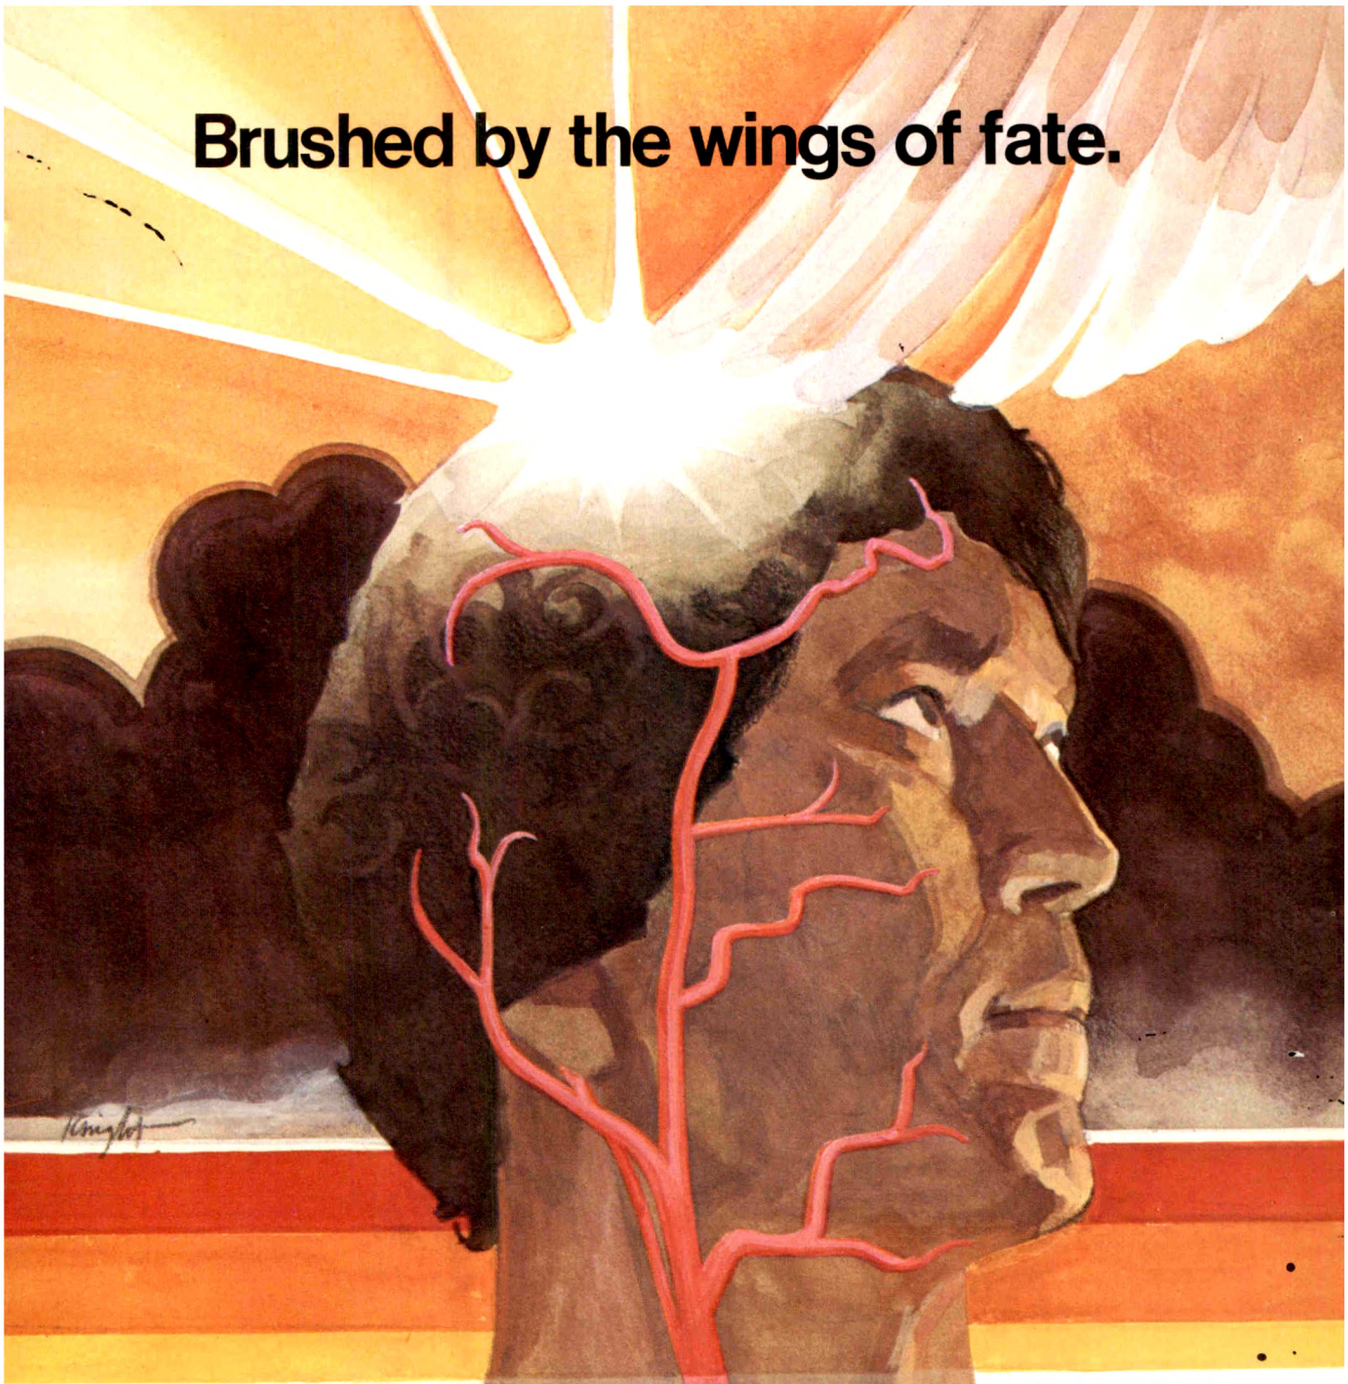


Pedalmate Ergometer
Manual or Automatic Heart Rate Control



Standard Treadmill
1-10 mph, 0-40% lift

Brushed by the wings of fate.



For men who have already felt the effects of cerebral ischemia, daily doses of aspirin provide significant protection against recurrence of stroke or TIA.

Ascriptin®—Maalox®-protected—is designed to give the full benefit of continuous, daily aspirin dosage without the high incidence of untoward gastrointestinal effects associated with ordinary aspirin preparations. By reducing GI unpleasantness, Ascriptin® may contribute significantly to better long-term adherence...and therefore better protective results.

The best of aspirin is

Ascriptin®

Aspirin 325 mg buffered with Maalox® 150 mg

1 tablet q.i.d. or 2 tablets b.i.d. to help prevent recurrent TIA in men

Reduced Risk Aspirin Therapy in the Conventional Dosage Range

- to help prevent TIA
- to relieve pain
- to reduce fever
- to aid in vascular headache
- to suppress platelet aggregation

The only antiprostaglandin therapy that has passed the test of time and experience, aspirin is probably the most widely used drug in the world. With the inclusion of Maalox® in the tablet, aspirin becomes Ascriptin®—keeping all its therapeutic effectiveness and reducing risk of GI intolerance—for even greater acceptability to occasional users as well as to patients on long-term or frequent dosage.

For the best of aspirin...

Ascriptin®

Aspirin, 325 mg ■ buffered with Maalox®, 150 mg

RECOMMENDED ASCRIPTIN® DOSE IN TIA's: 1300 mg/day
(two tablets b.i.d. or one tablet q.i.d.)

There is evidence that aspirin is safe and effective for reducing the risk of recurrent transient ischemic attacks or stroke in men who have had transient ischemia of the brain due to fibrin platelet emboli.
There is no evidence that aspirin is effective in reducing TIA's in women or is of benefit in the treatment of completed strokes in men or women. Patients presenting signs and symptoms to TIA's should have a complete medical and neurologic evaluation.
Consideration should be given to other disorders which resemble TIA's.
It is important to evaluate and treat, if appropriate, other disease associated with TIA's and strokes such as hypertension and diabetes.

Treatment of d-Transposition of the Great Arteries: Management of Hypoxemia After Balloon Atrial Septostomy

CATHERINE G. HENRY, MD
DAVID GOLDRING, MD, FACC
ALEXIS F. HARTMANN, MD, FACC
CLARENCE S. WELDON, MD, FACC
ARNOLD W. STRAUSS, MD

St. Louis, Missouri

Between 1975 and 1979, a group of 43 patients with d-transposition of the great arteries were diagnosed and underwent Rashkind balloon atrial septostomy at the time of initial catheterization. Thirty-six (88 percent) survived to the time of intraatrial baffle repair, and 31 (72 percent) are long-term survivors, 2 of them now awaiting repair. Palliative operations were performed in nine patients before definitive surgery; four of these patients are long-term survivors. Prostaglandin E_1 infusion improved oxygenation and relieved acidosis in four patients. It is concluded that most patients with d-transposition of the great arteries will survive to elective intraatrial baffle repair between 6 and 12 months without surgical palliation in spite of significant hypoxemia. Prostaglandin E_1 infusion may be life-saving and provide sufficient palliation in patients with persistent hypoxemia and acidosis after balloon atrial septostomy.

Since the introduction of the Rashkind balloon atrial septostomy in 1966[1] for management of infants with d-transposition of the great arteries in the neonatal period, early mortality has been reduced from about 50 percent in the 1st month of life before 1966,[2,3] to 10 to 15 percent since then.[4,5] Early deaths after balloon atrial septostomy have been due to congestive heart failure, sepsis, complications of balloon atrial septostomy, neurologic and renal problems and persistent hypoxemia.[3] Although balloon septostomy results in a marked increase in oxygen saturation immediately after the procedure in most cases,[7–9] significant hypoxemia often recurs even after creation of a sizable atrial septal defect.[10]

Opinion has varied about management of these persistently hypoxemic infants in the early period after atrial septostomy. Blalock-Hanlon septectomy is performed at some centers,[11–13] but the mortality rate of surgical septectomy is 20 to 25 percent[14,15] and the operation is often ineffective in relieving arterial desaturation.[3,16]

Recently, prostaglandin E_1, a potent dilator of the ductus arteriosus in the early neonatal period, has been noted to cause a significant rise in oxygenation in patients with transposition of the great arteries having persistent hypoxemia after balloon septostomy.[12,16–19] However, the effect has been transient in most cases, and subsequent management of these recurrently hypoxemic patients has varied. Some centers prefer to postpone definitive repair until the infant is at least 1 year old, performing intermediate palliation if indicated,[20,21] but most have recommended elective intraatrial baffle repair at age 1 year or earlier.[10,22–] More recently, primary repair in infants as young as 4 days of age with persistent hypoxemia after balloon septostomy has been performed with a high survival rate and small incidence of morbidity.[13,27,28]

In this paper we review our experience from 1975 to 1979 with patients with transposition of the great arteries and suggest guidelines for early management of patients with hypoxemia who have no significant obligatory shunt (ventricular septal defect or patent ductus arteriosus). We have found that the majority of patients without any obligato

shunt will have an arterial oxygen pressure level of less than 30 torr (oxygen saturation less than 60 percent) after creation of an adequately sized atrial septal defect by balloon septostomy, yet will survive to undergo elective intraatrial baffle repair between 6 and 12 months of age without a surgical palliative procedure. A subgroup of these patients will have hypoxemia and acidosis after balloon septostomy. We have used prostaglandin E_1 to treat four of these patients,[29] and all had subsequent improvement in oxygen and resolution of acidosis.

Methods

Patients: Between January 1, 1975 and December 31, 1979, 43 infants (36 male, 7 female) admitted to St. Louis Children's Hospital were found to have d-transposition of the great arteries on cardiac catheterization. The age at initial catheterization ranged from several hours to 5 months; 33 infants (77 percent) were studied in the 1st week of life (Fig. 1). Patients with valve atresia, univentricular heart or significant coarctation of the aorta were not included. A moderate to large shunt was demonstrated angiographically in 22 patients whose predominant lesion was a ventricular septal defect (12 patients) or a patent ductus arteriosus (10 patients). An additional seven patients had angiographic evidence of a small (less than 2 mm diameter) patent ductus arteriosus, and three patients had a small (less than 2 mm diameter), hemodynamically insignificant ventricular septal defect. Significant subpulmonary stenosis was demonstrated angiographically in one patient with intact ventricular septum on initial catheterization.

All patients underwent Rashkind balloon septostomy at the time of initial catheterization; a 3 to 4 ml (5 French Edwards) balloon was used in all cases except one, in whom a 1.5 ml (4 French) balloon was used because of the patient's small size (1,800 g).

Prostaglandin E_1 infusion: Four patients with marked hypoxemia and acidosis after Rashkind balloon septostomy received prostaglandin E_1 (Upjohn) infusion through an umbilical artery catheter with the tip at the level of fifth or sixth thoracic vertebra. Criteria for beginning prostaglandin E_1 infusions were (1) reduction in PaO_2 to 20 to 25 torr after balloon septostomy, and (2) concomitant acidosis (pH less than 7.35).

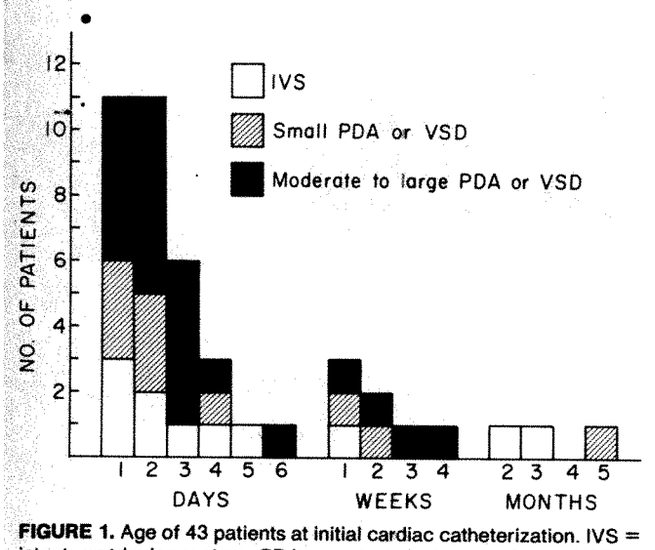

FIGURE 1. Age of 43 patients at initial cardiac catheterization. IVS = intact ventricular system; PDA = patent ductus arteriosus; VSD = ventricular septal defect.

Surgical therapy: Patients with a large ventricular septal defect at the time of initial catheterization underwent recatheterization at age 6 months, and those with an intact ventricular septum were recatheterized at age 6 to 12 months. Symptomatic patients underwent recatheterization before surgical palliation or early repair. The time of repair ranged from 3 months to 2 5/12 years, most elective repairs (25 of 36 patients with repair to date) being performed between 10 and 14 months of age. Early repair (3 to 10 1/2 months) was performed because of hypoxemia (four patients), marked growth failure (three patients) or cerebrovascular accident (one patient). The Mustard intraatrial baffle repair was performed in the initial 23 patients, of whom 13 had simple transposition with an intact ventricular septum and 10 had a previous palliative procedure requiring dismantling or additional anomalies, or both. Modified Senning procedures[31] were performed in the subsequent 13 patients, of whom 10 had simple transposition with an intact ventricular septum and 3 had additional associated lesions.

Results

Results of balloon atrial septostomy (Table I): Patients with a moderate to large patent ductus arteriosus or ventricular septal defect presented with a higher PaO_2 than did those with an intact ventricular septum or a small shunt. Rashkind septostomy resulted in substantial initial improvement in systemic oxygen saturation (10 to 62 percent) in all but five patients. Patients with a small ventricular septal defect responded to septostomy with a rise in PaO_2 similar to that of infants with an intact ventricular septum. Patients with a moderate to large ventricular septal defect or a patent ductus of any size had significantly greater increase in initial PaO_2 levels than did patients with an intact ventricular septum or a hemodynamically insignificant ventricular septal defect. Oxygen saturation after septostomy decreased to fairly stable levels within a few hours of the procedure and were not notably different from values before septostomy except in patients with a persistently patent ductus arteriosus, who had a sustained rise in oxygenation after septostomy. As compared with patients who had shunts, patients with an intact ventricular septum had substantially lower PaO_2 values after septostomy—less than 30 torr in all and less than 20 torr in five (50 percent of patients with an intact ventricular septum). An additional four of seven patients with a small patent ductus at initial catheterization had a PaO_2 less than 20 torr within 48 hours of balloon atrial septostomy, presumably secondary to ductal closure. Thus, patients with a patent ductus arteriosus in the early period after Rashkind septostomy had a significantly higher oxygen saturation than that of patients having only an intact ventricular septum. Indeed, the presence of a sizeable ventricular septal defect or patent ductus arteriosus was essential to maintain oxygen saturation above 60 percent in the early period after septostomy.

All but one patient with intact ventricular septum or small ventricular septal defect had PaO_2 less than 30 torr at the time of hospital discharge 2 to 14 days after

balloon septostomy (data not shown). The one exception was the patient with significant subpulmonary stenosis on initial catheterization who underwent Blalock-Taussig shunt at age 5 days with a resultant increase in PaO_2 to a mean of 36 torr. All other patients with intact ventricular septum were doing well at the time of discharge in spite of low oxygen saturation. Furthermore, all had oxygen saturation greater than 60 percent at the time of elective catheterization before definitive surgery (Table I). Two patients with an intact ventricular septum and a small patent ductus arteriosus at initial catheterization had satisfactory oxygenation at time of initial hospital discharge but required early operative intervention (at age 1 and 9 months, respectively) because of increasing cyanosis. The other patients in this group had satisfactory oxygenation at later elective catheterization. Thus, initial hypoxemia occurring after balloon septostomy in patients with intact ventricular septum was well tolerated and oxygenation increased to satisfactory levels without need for additional surgical intervention. There were no early deaths that could be attributed directly to the procedure and no early or late deaths because of an inadequate atrial septostomy.

As a further measure of the adequacy of balloon septostomy, the size of the atrial septal defect was assessed at the time of operation or postmortem examination. The atrial septal defect was large (1.5 to 2.5 cm) in 27, moderate (1 to 1.5 cm) in 4 and small (less than 1 cm) in 4. Of the four patients with a small atrial septal defect noted at operation, two had undergone repeat catheterization 24 hours and 2 weeks after the initial balloon septostomy procedure because of marked hypoxemia (PaO_2 less than 20 torr). A widely patent atrial septal defect was demonstrated angiographically and by pressure data in both patients. The other two patients had satisfactory oxygenation (PaO_2 30 to 50 torr) during the 1st week after septostomy. Furthermore, persistent hypoxemia after septostomy occurred frequently in patients who had an anatomically documented large atrial septal defect. Thus, there was no correlation between the size of an atrial septal defect a later surgical repair or autopsy and level of oxygenatio in the period immediately after septostomy.

Results of surgical palliation (Table II): Nin patients (21 percent) underwent a palliative surgica procedure. In 1975 three patients with severe hypox emia had a Blalock-Hanlon septectomy performec Because of poor results with this procedure (two deaths and our realization that hypoxemia was usually not du

to a small atrial septal defect (see preceding), this procedure has not been used since 1975.

Instead, we provided palliation for hypoxemia in five patients with a Blalock-Taussig shunt. In three of these, decreased pulmonary blood flow secondary to subpulmonary stenosis was the cause of the hypoxemia.[32] In the other two, a Blalock-Taussig shunt was performed in the absence of subpulmonary stenosis. One of these patients, who previously had demonstrated increased oxygenation during prostaglandin E_1 infusion, was also improved following the shunt procedure (Fig. 2). Although no operative mortality occurred, two patients had significant morbidity from paralysis of the right hemidiaphragm and one shunt was nonfunctional.

Results of palliation with prostaglandin E_1 infusion: Four patients were treated with prostaglandin E_1 because of hypoxemia (PaO_2 16 to 21 torr) and acidosis (pH less than 7.35) after adequate balloon septostomy (Fig. 2). Dilatation of the ductus arteriosus occurred in all, including one patient who had a closed ductus at the time of initial angiography (Fig. 3). Prostaglandin E_1 infusions resulted in a nearly maximal rise in PaO_2 within 15 minutes in two patients but took 2 hours for notable rises and 7 hours for maximal rises

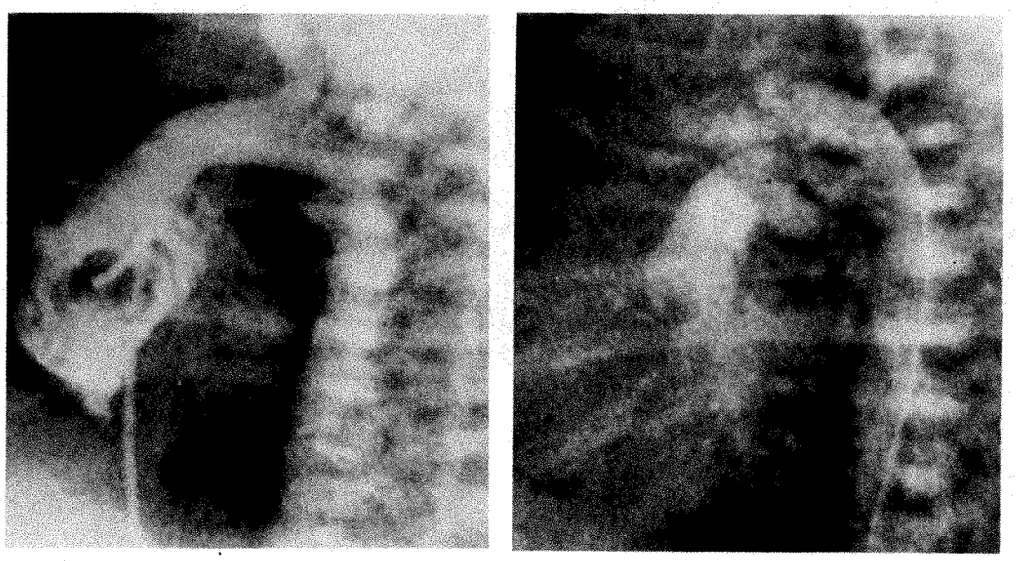

FIGURE 3. Ductal dilatation by prostaglandin E_1 demonstrated on angiography. **Left,** right ventricular injection (left anterior oblique projection) at the time of initial catheterization demonstrates ductus infundibulum with closed ductus arteriosus. **Right,** aortogram (left anterior oblique projection) during prostaglandin E_1 infusion demonstrates widely patent ductus arteriosus 15 hours later.

in the other two. During infusion, PaO_2 rose to 30 to 40 torr and acidosis was relieved in all patients. Total duration of prostaglandin E_1 infusions ranged from 50 to 108 hours. Discontinuation of the drug resulted in a reduction in PaO_2 to preinfusion levels in all patients with gradual improvement to mid-high 20 torr level by the time of discharge. In an effort to simulate the beneficial effect of prostaglandin E_1 infusion, one patient underwent a successful Blalock-Taussig shunt. The other three patients tolerated hypoxemia without further development of significant acidosis, and they subsequently underwent successful definitive repair electively at age 10 to 12 months.

Mortality and results of corrective surgery (Table III): Five patients died before definitive repair. One patient died a few hours after initial catheterization with E. coli meningoencephalitis and another patient with a large ventricular septal defect had fatal congestive heart failure and renal failure at age 6 months. Three deaths followed palliative surgery.

In addition, there were seven deaths at the time of or subsequent to definitive repair (Tables III and IV). Three patients were unable to regain adequate cardiac function without cardiopulmonary bypass. A fourth patient, who had undergone pulmonary arterial banding in the 1st week of life, died of low output secondary to tricuspid insufficiency after repair. Another patient with a patent ductus arteriosus and congestive heart failure survived repair at 7 months of age but died one month later of respiratory failure. Two patients survived initial repair but died during a subsequent surgical attempt to relieve baffle obstruction of systemic or pulmonary venous return. No late deaths due to arrhythmias or sudden deaths have occurred.

Thus, of our 43 patients, 31 (72 percent) are living, including 29 patients who have had intraatrial baffle repair and have been followed up for 2 months to 4 1/2 years, and 2 patients who are awaiting surgical repair. Thirty-six (88 percent) of 41 patients survived to definitive repair at age 7 months to 2 5/12 years; only two deaths (5 percent) occurred in those patients who underwent balloon septostomy without further palliation. Mortality was substantially greater in those patients who underwent surgical palliation before definitive repair. Of the nine patients who had surgical palliation, only four are long-term survivors.

Discussion

Factors contributing to improved survival: Survival of infants with transposition of the great arteries has been improved dramatically since the introduction of the Blalock-Hanlon septectomy, balloon atrial septostomy and the venous transposition operations described by Mustard and Senning. With current management, deaths in the 1st month of life (10 to 15 percent)[6] have contributed significantly to overall mortality. In contrast, only three of our patients (7 percent) died in the first 5 months of life. We believe that early referral of our patients (Fig. 1) was one important factor in their survival since few were severely acidotic at time of admission (16 percent with pH less than 7.25). Improved survival of infants with transposition concomitant with earlier referral to centers equipped to perform emergency balloon septostomy was also noted in a recent survey.[15]

Second, performance of a technically adequate balloon septostomy contributed to the high rate of early survival in our patients. Although others have reported mortality due to complications of balloon septostomy,[33–35] at our institution this procedure has not been associated with any deaths in the last 5 years.

A third factor that contributed to excellent early survival was conservative medical management without further surgical palliation in patients whose early

*Includes two patients with ligation of a patent ductus arteriosus (one operative and one late death), two with ligation of a Blalock-Taussig shunt (one late death), two with closure of ventricular septal defect and resection of left ventricular outflow tract obstruction, one with closure of a ventricular septal defect, one with resection of left ventricular outflow tract obstruction, one with closure of a ventricular septal defect and pulmonary valvotomy, and one with ligation of a Blalock-Taussig shunt and resection of left ventricular outflow tract obstruction. †Included one patient with closure of a ventricular septal defect and resection of left ventricular outflow tract obstruction, one with ligation of a patent ductus arteriosus and one with repair of tricuspid valve, debanding of pulmonary artery, angioplastic reconstruction of pulmonary artery and closure of a ventricular septal defect (operative death).

post-septostomy oxygen saturations were "unsatisfactory" as defined in the past. Satisfactory early improvement after balloon septostomy has been previously defined as either an increase in oxygen saturation of greater than 10 percent with reduction in interatrial mean pressure gradient to less than 2 mm[20,35] or arterial saturation of greater than 50–75 percent.[11–14,20] Satisfactory late improvement has been defined as survival to six months with oxygen saturation at 60 percent or higher.[20,22,36] At other institutions, Blalock-Hanlon septectomy has been the most frequent form of palliation in infants who have not improved significantly after balloon atrial septostomy. However, this operation carries a 20 to 25 percent mortality rate.[14,15] In our series, the only deaths in patients with an oxygen saturation of less than 60 percent (PaO_2 less than 30 torr) after balloon septostomy occurred in those who underwent palliative procedures (Table III). Indeed, although most patients with an intact ventricular septum or small ventricular septal defect or patent ductus arteriosus were transiently hypoxemic early after balloon septostomy, none of our 21 patients in these groups who were managed medically died in the neonatal period, except one with E. coli meningoencephalitis. Early hypoxemia resolved over time and remained at satisfactory levels in all but five patients (three with left ventricular outflow obstruction). Thus, we believe that hypoxemia alone is not a sufficient indication for surgical septectomy early after technically adequate balloon septostomy.

Surgical septectomy is often ineffective in relieving arterial desaturation[3,16] and does not guarantee permanent presence of an atrial septal defect because subsequent spontaneous closures have been noted on occasion.[14] Thus, the only cases in which Blalock-Hanlon septectomy might be indicated in the immediate period after balloon septostomy would be those in whom atrial septal defect size is determined to be inadequate by two-dimensional echocardiography[16] or a repeated catheterization. Indeed, subjection of a markedly hypoxemic infant to Blalock-Hanlon septectomy may be an unnecessary stress, and might account for some avoidable mortality.

Prostaglandin E_1 infusion: A fourth factor that contributed to the high rate of early survival in our patients was use of prostaglandin E_1 infusion in four hypoxemic newborns with associated acidosis (pH less than 7.35) after balloon septostomy. Acidosis and hypoxemia were relieved in all four. Previous authors have described use of prostaglandin E_1 in patients with transposition with variable success. Of the 18 patients with transposition and intact ventricular septum treated with prostaglandin E_1 and reported on to date,[12,16–19] all but four showed an increase in oxygen saturation. Successful ductal dilatation by prostaglandin E_1 has been accomplished as late as 28 days of age,[37] but it is less likely to occur after the first week of life.

In our patients, as well as those reported on previously,[12,17–19] discontinuation of prostaglandin E_1 infusion resulted in return of oxygen saturation to preinfusion levels, implying ductal closure. However, acidosis did not recur despite low oxygen saturation. Rather, a brief period (2 to 4 days) of prostaglandin E_1 infusion served to relieve acidosis secondary to hypoxemia present on admission or subsequent to the stress of cardiac catheterization, angiocardiography and balloon septostomy. The patients were then able to tolerate hypoxemia without the development of further metabolic acidosis.

Blalock-Taussig shunt: Relief of persistent or recurrent hypoxemia and acidosis after balloon septostomy with prostaglandin E_1 infusion may be the only palliation necessary in patients without significant left ventricular outflow tract obstruction. However, if acidosis recurs with discontinuation of prostaglandin E_1, a Blalock-Taussig shunt will improve oxygenation by simulating the hemodynamics of a patent ductus arteriosus (Fig. 2). Although palliation of transposition by aortopulmonary anastomosis has been suggested before,[18,38] it is currently not accepted as standard treatment except in patients with pulmonary stenosis.[3,11,21,39] Indeed, most reported attempts to create aortopulmonary anastomoses in neonatal transposition have resulted in congestive heart failure[40] and a high mortality rate (approximately 75 percent).[15] Our experience with the Blalock-Taussig shunt in transposition (Table II) is limited; however, no operative deaths occurred and the shunt generally improved oxygenation. Furthermore, because of the small size of the shunt, there was no instance of congestive heart failure and four of the five patients who had a Blalock-Taussig shunt survived to successful intraatrial baffle repair. We believe that a Blalock-Taussig shunt may be an acceptable palliative procedure in infants with transposition and subpulmonary stenosis[32] or in neonates with transposition and persistent acidosis who have demonstrated a positive response to prostaglandin E_1.

Indications for early definitive surgical repair: Some controversy has recently arisen concerning the optimal age for repair in patients with transposition of the great arteries. Early definitive repair has been advocated by several workers,[23,26,27,40,41] but the mortality rate in infants less than 2 months old is high in some series.[15,22] However, in the most recent series[13,27,31,42] operative mortality rates have been low (0 to 7 percent) in patients treated with definitive repair, even in the neonatal period, without intervening palliative procedures. Persistent hypoxemia after technically adequate balloon septostomy was the reason given most often for early reparative intervention. However, hypoxemia alone may be well tolerated without need for early operative intervention. We found that 88 percent of our patients survived to definitive repair (average age 11.6 months) with an operative mortality of 11 percent. These results compare favorably with those of other recent series which report a 19 to 27 percent mortality rate before repair[3,6,20,35,39] and an 11 to 26 percent mortality rate at definitive operation.[3,6,10,15,20,22,23,41] Thus, we feel justified in waiting to perform elective repairs at ages 6 to 10 months with the hope that ventricular septal defects will close in some patients and

that venous obstructive complications of intra-atrial baffle repairs may be avoided in older patients.

Guidelines for early management: As a consequence of our findings, we suggest the following guidelines for early management of patients with transposition of the great arteries: (1) balloon atrial septostomy and conservative medical management for all patients without acidosis regardless of oxygen saturation following Rashkind septostomy, (2) prostaglandin E_1 infusion for 2 to 5 days in those patients with persistent acidosis after balloon septostomy with more prolonged infusion if significant acidosis recurs after discontinuation of the drugs,[19] and (3) early Senning or Mustard intraatrial baffle repair in any patient over one month of age with growth failure, uncontrolled congestive heart failure or increasing cyanosis caused by catheterization-proven subpulmonic stenosis, increasing pulmonary vascular resistance or inadequate atrial septal defect. Blalock-Taussig shunt may be considered as an alternative in patients with subpulmonic stenosis or persistent hypoxemia in the first 1 to 2 months of life. Use of these guidelines may further improve the overall prognosis above the 72 percent late postoperative survival which we have already achieved.

Acknowledgment

We thank Jim Arnold (Upjohn) for providing prostaglandin E_1, Charles Crawford for technical assistance, Marge Norris and Aileen Derhake for preparation of the manuscript, and the housestaff and nurses of St. Louis Children's Hospital for their help in the care of the patients.

Addendum

Since the preparation of this report, the two remaining patients awaiting definitive repair have undergone a successful Senning operation.

Thirty patients with ventricular septal defect and d-transposition of the great arteries or double outlet right ventricle underwent placement of an intraventricular baffle to achieve physiologic correction. Eighteen of these patients also required an external conduit to establish continuity between the right ventricle and the pulmonary artery. There was an overall 22 percent early mortality rate, although the rate was 63 percent in patients who weighed less than 10 kg. There was an additional 20 percent late mortality rate, primarily related to conduction disturbances and pulmonary vascular obstructive disease, problems that have not occurred in patients operated on since 1974. Of the survivors, all are asymptomatic and as a group have achieved a significant weight gain. Many have residual hemodynamic abnormalities that required cardiac catheterization for precise assessment. Four patients have been reoperated on, with no additional mortality.

With advances in surgical technique, a wide variety of complicated forms of congenital cardiac defects have been treated by cardiovascular surgeons. Previous reports have described an intraventricular baffle procedure performed in patients with d-transposition of the great arteries and ventricular septal defect[1–6] and patients with double outlet right ventricle and ventricular septal defect[5–10] to achieve physiologic correction of the circulation. When this procedure is employed, all patients with d-transposition of the great arteries and ventricular septal defect[1–6] require interposition of an external conduit between the body of the right ventricle and the pulmonary artery. Patients with double outlet right ventricle and ventricular septal defect who have anomalies of the pulmonary or coronary arteries also require an external conduit.[5,6] Previous reports have described the surgical technique and operative mortality[1–10] or selected hemodynamic findings[4–6,11,12]; in this report, we describe comprehensive long-term follow-up findings in 30 patients who underwent an intraventricular baffle procedure.

Methods

Patient groups: Between March 1970 and March 1978, a total of 14 patients with d-transposition of the great arteries and ventricular septal defect (Group I) and 16 patients with double outlet right ventricle and ventricular septal defect (Group II) underwent intracardiac repair at this institution. Complete diagnosis and previous surgical procedures for each patient are listed in Table I. In all patients, two ventricles communicated through a ventricular septal defect, and the aorta arose from the right ventricle. In Group I the pulmonary artery arose from the left ventricle. In Group II, both the aorta and the pulmonary artery arose from the right ventricle: in 11 patients the ventricular septal defect was subaortic, and in 5 the defect was subpulmonary.

Surgical procedure: With use of cardiopulmonary bypass, a knitted Teflon patch was fashioned inside the right ventricle so that left ventricular blood was ejected through the ventricular septal defect, remained on the left side of the baffle and was directed out the aortic root. Right ventricular outflow was managed as follows: (1) In 18 patients—all 14 patients in Group I and 4 patients in

ASD = atrial septal defect; A-V = atrioventricular; BT = previous subclavian-pulmonary arterial anastomosis; CHB = complete heart block, pacemaker implanted; CHF = congestive heart failure; Cond obstr = obstruction to right ventricular outflow inside external conduit, proximal to heterograft valve; Dex = dextrocardia; Hct = hematocrit; Glenn = previous superior vena cava–right pulmonary arterial anastomosis; Inf PS = infundibular pulmonary stenosis; LSVC = persistent left superior vena cava; LV-RA = residual shunt from the left ventricle to the right atrium; PAB = previous pulmonary arterial band; PDA = patent ductus arteriosus; postop = postoperative; Potts = previous descending aorta–pulmonary arterial anastomosis; Pulm At = pulmonary atresia; PS = pulmonary valve stenosis; PVCs = occasional premature ventricular complexes; PVOD = pulmonary vascular obstructive disease; Reop = reoperation; Res VSD = residual ventricular septal defect (intraventricular communication); SBE = subacute bacterial endocarditis; Sub As = subaortic stenosis; sup PS = supravalvular stenosis of pulmonary arteries; Sys O_2 Sat = systemic oxygen saturation; TB = Taussig-Bing anomaly (subpulmonary ventricular septal defect); (u) = unvalved external conduit.; Wat = previous ascending aorta–right pulmonary arterial anastomosis.; Wt = body weight.

Group II—the pulmonary artery was divided and the proximal stump oversewn; a woven Dacron® conduit was interposed between the right ventriculotomy and the distal stump of the pulmonary artery. This conduit was unvalved in 4 patients treated early; in the other 14 patients a porcine aortic valve prosthesis[3] was incorporated into the Dacron conduit. (2) In the remaining 12 patients, all in Group II, an external conduit was not utilized, but 11 of these patients required infundibular resection or supravalvular pericardial patch, or both.

Surgical outcome: There are three categories of outcome: (1) early death (less than 1 month after operation), (2) late death (more than 1 month after operation), and (3) survival. To evaluate the variables that may have influenced the surgical result, surgical outcome was correlated with preoperative hematocrit, systemic arterial oxygen saturation, age, weight and performance of previous palliative procedures. Also, to investigate the effects of accumulated experience with the surgical procedures at Stanford Medical Center, the outcome in the first 15 patients were compared with the outcome in the last 15 patients. Comparisons within these groups were made using the chi-square test for statistical significance.[13]

Postoperative follow-up: Follow-up information was obtained directly from 20 patients and from the referring physician of 10 others. Of the surgical survivors, 16 patients underwent cardiac catheterization 6 months to 5 years postoperatively. To assess the effect of surgery upon growth of the survivors, body weight at the time of cardiac catheterization was expressed as the number of standard deviations from the mean value in age- and sex-matched control subjects;[14] comparison was made between the values obtained at preoperative catheterization and postoperative catheterization using the two-tailed t test.[13]

Results

Clinical profiles: Fifteen of the 30 patients were male and 15 female (Table I). Of the 14 patients in Group I, 11 had pulmonary stenosis or atresia, and 7 of these had undergone previous surgical creation of a systemic to pulmonary arterial shunt; the 3 patients without pulmonary stenosis had not had previous surgery. Among the 16 patients in Group II, pulmonary stenosis was present in 10, including 4 in whom a systemic to pulmonary arterial shunt had been performed; of the 6 patients without pulmonary stenosis, 4 had had pulmonary arterial banding and in 1 of of these, subpulmonary stenosis had developed at the time of intracardiac repair.

Early mortality (Table I): Seven patients—two in Group I and five in Group II—died in the early postoperative period: five with low output, one of respiratory insufficiency, and one with postoperative cerebral damage. There was a significant relation ($p < 0.05$) between mortality and age less than 3 years. However, there was a better correlation between early mortality and weight ($p < 0.01$): Children who weighed less than 10 kg had a 62 percent operative mortality rate compared with 9 percent in patients who weighed more than 10 kg (Fig. 1). Because size significantly influenced early mortality, when the infants who weighed less than 10 kg were excluded from consideration, neither previous operative procedures nor operative experience at Stanford with these defects influenced operative mortality. Finally, the most complex combination of defects was found in our five patients with double outlet right

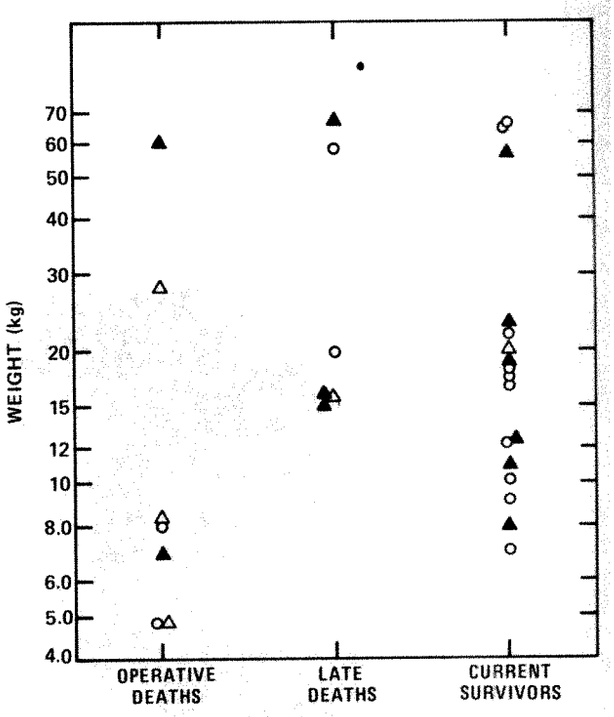

FIGURE 1. Surgical outcome in 30 patients plotted against body weight. **Open circles** = d-transposition of the great arteries and ventricular septal defect; **open triangles** = double outlet right ventricle and subpulmonary ventricular septal defect; **closed triangles** = double outlet right ventricle and subaortic ventricular septal defect.

ventricle and subpulmonary ventricular septal defect three of these five patients died early, including two who weighed less than 10 kg. Neither preoperative systemic arterial oxygen saturation nor hematocrit correlated with surgical survival.

Postoperative Evaluation

By history, all 17 current survivors are acyanotic and have improved exercise tolerance compared with that before operation. Patient 19 had findings of congestive heart failure after his first intracardiac procedure, but is now asymptomatic after reoperation. Patient 2 had Moraxellei Kingsei endocarditis, and recovered uneventfully after intravenous ampicillin therapy. Patient 12 had recurrent Candida septicemia, the cause of death 3 months after surgery.

Electrocardiographic findings, except for arrhythmias, are nonspecific, as each patient has a right bundle branch block. Patients 21, 23 and 25 had a pacemaker implanted for surgical complete heart block. Two of these patients subsequently died and, after pacemaker failure, the third has second degree heart block with 2:1 atrioventricular conduction and a ventricular rate of 75/min. Patients 10 and 13 have unifocal premature ventricular complexes at rest and Patient 10 in addition has a variety of supraventricular arrhythmias.

Chest radiographic findings are nonspecific, showing normal heart size or slight cardiac enlargement. Pulmonary vascularity appears normal in all. In patients with a valved conduit, the metallic ring associated with the heterograft valve is also seen.

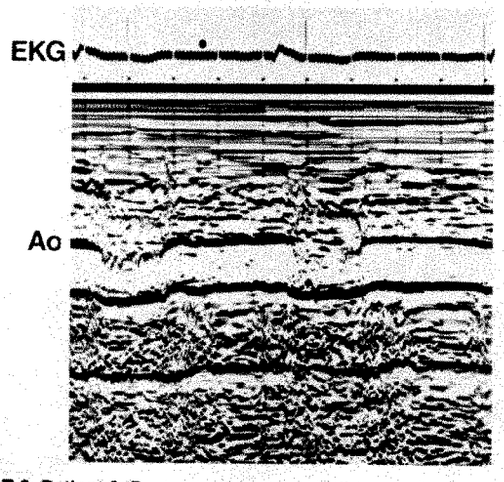

FIGURE 2. Patient 3. Postoperative echocardiogram showing systolic notching and shuddering of aortic valve. Ao = aortic root; EKG = surface electrocardiogram.

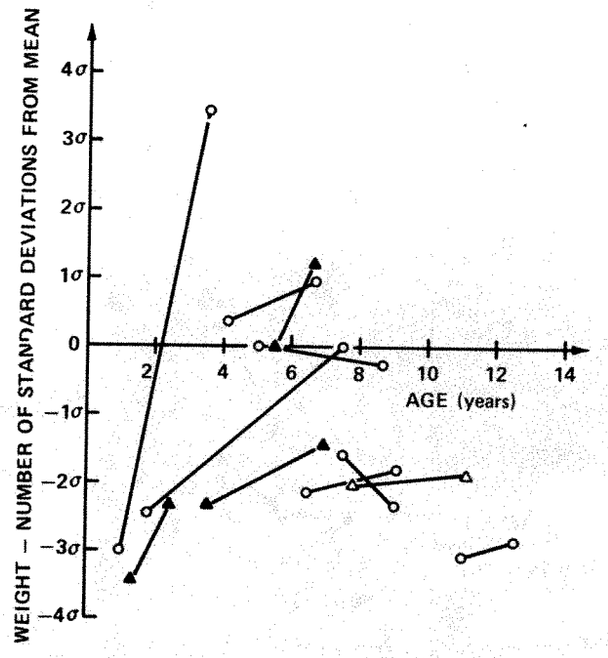

FIGURE 3. Pre- and postoperative body weights (expressed as the number of standard deviations from the mean value of age- and sex-matched control subjects) are plotted on the **vertical axis**. For each pair, the symbol at left was obtained at preoperative cardiac catheterization and the symbol at right at postoperative catheterization. Symbols as in Figure 1.

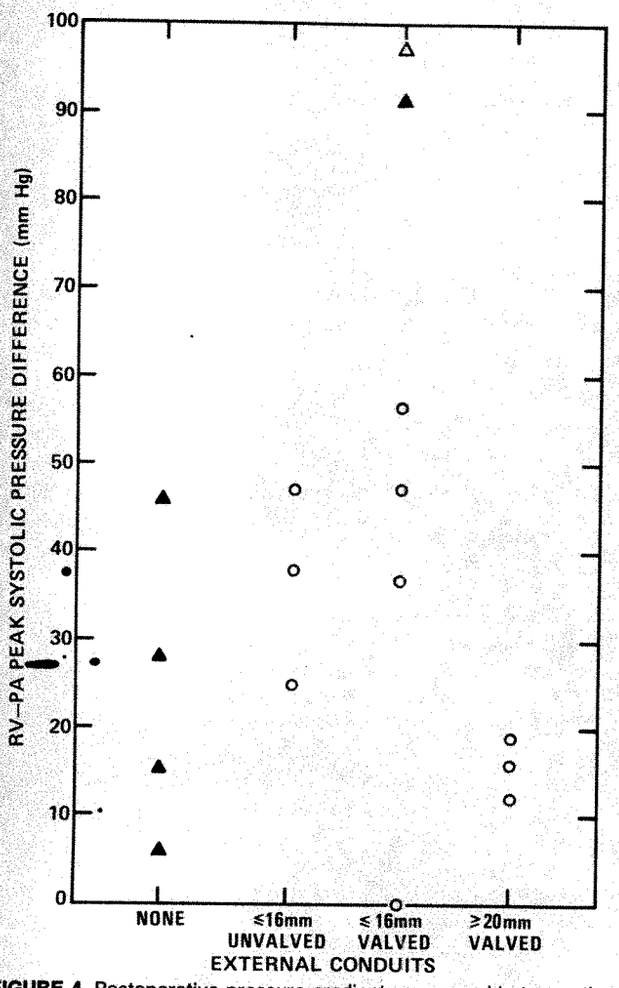

FIGURE 4. Postoperative pressure gradients measured between the body of the right ventricle (RV) and distal pulmonary artery (PA), related to type of reconstruction. Symbols as in Figure 1. None = no external conduit; ≤16 mm = 14 or 16 mm external conduit; ≥20 mm = 20 or 25 mm external conduit; VALVED = porcine heterograft valve incorporated into external conduit; UNVALVED = straight Dacron tube used as external conduit.

Echocardiography was often technically difficult in these patients, and we have been unable to image motion of the porcine heterograft valve with consistency. Notching and shudder of the aortic valve motion was often seen (Fig. 2), although this finding does not correlate with the presence of subaortic obstruction.[15]

Postoperative weight percentiles (Fig. 3), adjusted for age and sex, obtained at postoperative cardiac catheterization were significantly greater than preoperative catheterization values ($p < 0.05$); the largest gains were seen in those patients who were less than 6 years old at the time of operation.

On physical examination, all surviving patients have at least a grade 3/6 systolic murmur, and two patients with an unvalved external conduit have a diastolic murmur. The murmurs were generated by residual intracardiac defects, which can only be defined by cardiac catheterization.

Cardiac catheterization (Table II): The results can be summarized as follows:

Right ventricular outflow tract obstruction: Eight patients had a peak systolic gradient greater than 30 torr across the right ventricular outflow tract (Fig. 4). The largest gradients were found in patients in whom a 14 or 16 mm external conduit was used, and of these the conduits that contained heterograft valves were most stenotic. Obstruction was found at the junction of the right ventricle and external conduit (four patients), in the external conduit below the heterograft valve (three

Ao = aortic; Baf = obstruction to left ventricular outflow at a region inside the intraventricular baffle; Band = obstruction to right ventricular outflow at site of previously placed pulmonary band; Cond-RV = obstruction to right ventricular outflow at junction of external conduit and right ventricle; PA = pulmonary arterial; Qp/QS = pulmonary/systemic flow ratio; RV = right ventricular; VSD* = obstruction to left ventricular outflow at the site of the natural ventricular septal defect. Other abbreviations as in Table I.

patients) (Figure 5) and at the point of a previous pulmonary arterial band (one patient).

Left ventricular outflow tract obstruction: Seven patients had a peak systolic gradient of 30 mm or more across the left ventricular outflow tract (Fig. 6). Although the trend was not statistically significant, small patients tended to have a larger gradient. At cardiac catheterization, the obstruction was in the intraventricular baffle in three patients (Fig. 7), at the site of the patient's natural ventricular septal defect in two and was not well localized in two.

Residual shunts: Six patients had a residual left to right shunt related to the intraventricular baffle. In four patients, the shunt was from the left to the right ventricle, and the communication was behind the septal leaflet of the tricuspid valve. In two others, the shunt was from the left ventricle to the right atrium. In all cases, pulmonary flow was less than twice systemic flow, and in two patients, the residual shunt was detected only on angiography (Fig. 7).

Pulmonary vascular obstructive disease: The highest pulmonary arterial pressures were found in two patients (Cases 10 and 24) who had previously had a surgically created aortic to pulmonary arterial shunt; the next highest pressures were found in two patients (Cases 13 and 14) who were operated on as adults. Mean pulmonary arterial pressure was at the upper limits of normal in four other patients, one of whom had a residual intracardiac shunt at postoperative cardiac catheterization.

Reoperation

Only Patient 17 was symptomatic after operation; this patient and three others (Patients 9, 20 and 29) were reoperated on and all did well after reoperation. Reoperation included closure of a residual left to right shunt (Patient 29), closure of a residual shunt and enlargement of the left ventricular outflow tract by removing a portion of the rim of the native ventricular septal defect (Patients 9 and 17) or replacement of the valved external conduit (Patient 20). In the latter patient, the conduit was replaced with a 20 mm valved conduit 3.7 years after the original implantation. The leaflets of the replaced valve were in excellent condition and the valve appeared to be competent; however, below the valve, a very exuberant fibrous reaction severely compromised flow into the conduit (Fig. 5). The porcine valve in Patient 9 was also visualized from above at the time of reoperation, and appeared to be in excellent condition. Reoperation was suggested to the family of Patient 25, but was refused because the boy is asymptomatic.

Late Mortality

There were six late postoperative deaths (Fig. 8): two 2 and 7 years, respectively, after operation, from progressive pulmonary vascular obstructive disease; two 6 months and 2 years, respectively after operation in patients who had complete heart block intraoperatively and had had a pacemaker implanted; one, 3 months after operation from Candida endocarditis; and one sudden and unexplained, 2 years after operation. Five of the six late deaths occurred in the first 15 patients in our series. In the later group, no patient had surgical complete heart block, and surgery was performed before the development of irreversible pulmonary vascular changes.

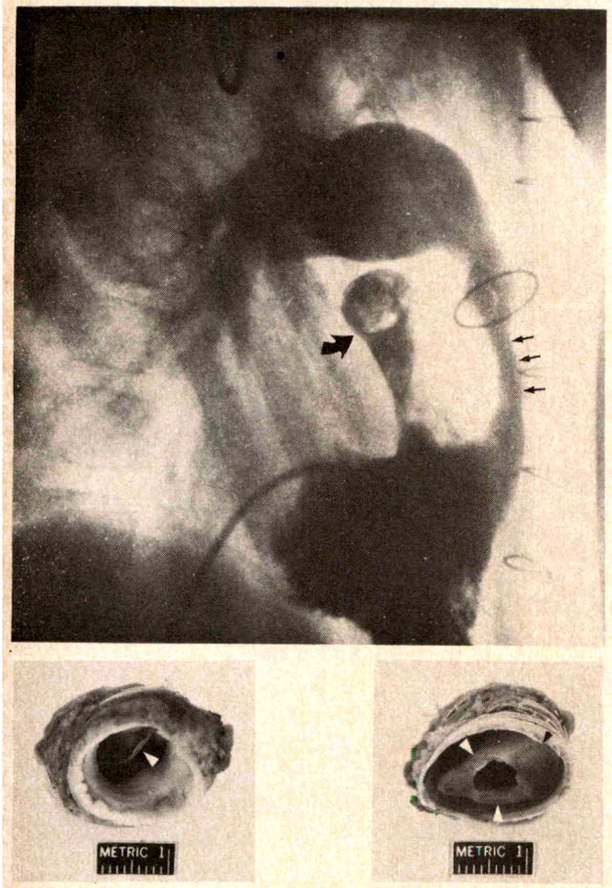

FIGURE 5. Patient 20. **Top,** lateral view of right ventriculogram 3.4 years after operation; note native pulmonary artery and pulmonary valve (**large arrows**). Because of a large gradient across a region of the valved conduit (**small arrows**), the conduit was replaced. **Bottom left,** view into the replaced conduit, distal to the porcine heterograft valve. The leaflets (**arrowhead**) are thin. **Bottom right,** view into the conduit proximal to the heterograft valve; note the fibrocalcific reaction (**arrowheads**), which shrank away from the conduit during fixation. The diameter of the effective orifice is about one third of that of the conduit.

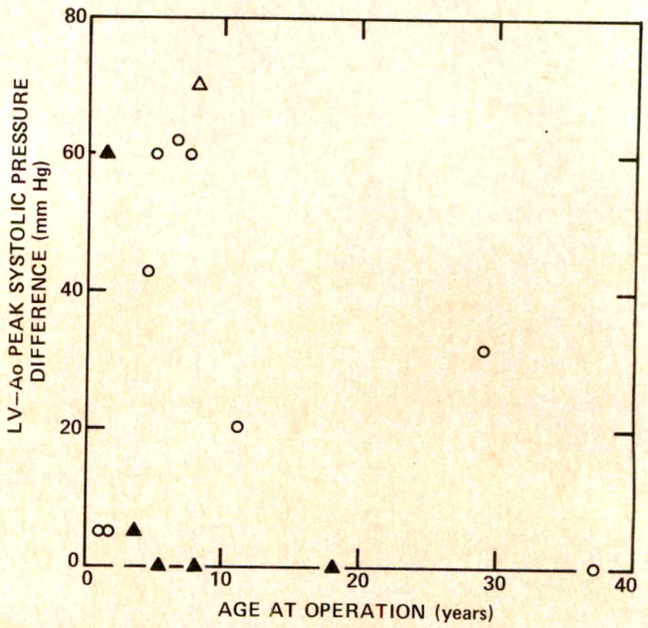

FIGURE 6. Peak systolic pressure gradient between the body of the left ventricle (LV) and the aorta (Ao), measured at postoperative cardiac catheterization, plotted against age at operation. Symbols as in Figure 1.

Discussion

Factors related to surgical mortality: Earlier reports[2–5,9,10] emphasized several factors related to surgical mortality, including size and complexity of the lesion, pulmonary vascular resistance, previous palliative procedures and experience with the surgical procedure. In our series, the major factor related to early mortality was small patient size: The risk of surgical death was 7 times higher in patients who weighed less than 10 kg than in patients who weighed more than 10 kg. Mortality was also greater in patients with the most complex combination of lesions: Only one of the five patients with double outlet right ventricle and subpulmonary ventricular septal defect is still alive. Neither pulmonary vascular resistance nor previous palliative procedures affected early surgical mortality. However, the two patients with the highest pulmonary vascular resistance, both of whom had had a prior systemic to pulmonary arterial shunt procedure, subsequently died.

Experience with the surgical procedures influenced outcome in two conflicting ways. There was a reduction in late mortality in our last 15 patients compared with that in our first 15: The electrophysiologic abnormalities in the early group did not occur in the later group, and the latter patients were operated on before irreversible pulmonary vascular resistance change developed. Conversely, because of the current emphasis on early repair of intracardiac defects, the later group of patients contained a larger proportion of children who weighed less than 10 kg, a group that continues to have an excessive early mortality.

Postoperative morbidity: Although mortality is a necessary consideration in assessing the risks of surgery, postoperative morbidity is also important. All of our 17 current survivors are asymptomatic, and many have achieved a significant augmentation in weight gain. Previous reports[4–6,11,12] of the intraventricular baffle procedure have described electrophysiologic and hemodynamic abnormalities, and both have occurred in our patients. Hemodynamic abnormalities include obstruction to outflow from both ventricles, residual intracardiac shunts and pulmonary hypertension. Significant electrophysiologic abnormalities were present in only five of our patients, although two with surgically induced complete heart block died, and a third requires digoxin to control supraventricular tachyarrhythmias.

Only two patients had virtually no hemodynamic abnormalities. Only five have had hemodynamic find-

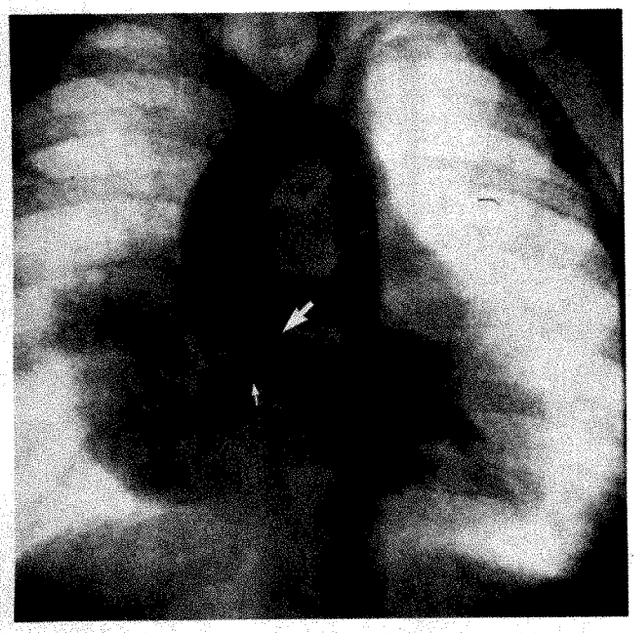

FIGURE 7. Patient 17. Frontal view of postoperative left ventriculogram. Obstruction to outflow (**large arrow**) is seen in the intraventricular baffle below the aortic valve. In addition, there is a trivial shunt (**small arrow**) from the left ventricle to right atrium.

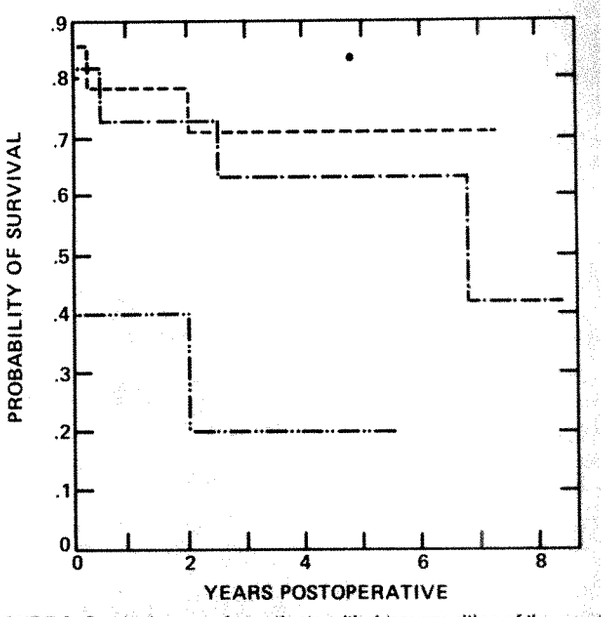

FIGURE 8. Survival curves for patients with d-transposition of the great arteries and ventricular septal defect (– –), double outlet right ventricle and subaortic ventricular septal defect (–·–) and double outlet right ventricle and subpulmonary ventricular septal defect (—··—).

ings severe enough to warrant reoperation, although we anticipate that more patients will be reoperated on as they grow. There has been no additional mortality in the four patients who were reoperated on to date.

Recommended guidelines for surgical treatment: On the basis of this series, we have adopted the following approach to treatment of patients with d-transposition of the great arteries and ventricular septal defect or double outlet right ventricle and ventricular septal defect. Because of the high mortality rate of intracardiac surgery in patients who weigh less than 10 kg, a palliative procedure is performed in infants refractory to medical management. Palliative procedures include (1) a systemic to pulmonary arterial shunt, preferably from the subclavian to the pulmonary artery,[16] for inadequate pulmonary blood flow, and (2) a pulmonary arterial band[17] for patients with excessive pulmonary blood flow. In patients weighing more than 10 kg, intracardiac surgery may be deferred if the pulmonary pressure is not elevated. We agree with others[2,9] that mid childhood is the optimal time for surgical repair with intraventricular baffle. Patients with double outlet right ventricle and subpulmonary ventricular septal defect present an especially difficult problem and we recommend an intraatrial baffle and closure of the ventricular septal defect,[18] rather than an intraventricular baffle alone to achieve a physiologic repair. The intraatrial baffle procedure has also been used in patients with d-transposition of the great arteries and ventricular septal defect,[19] but the mortality has been higher than that in our patients, and our patients have the additional advantage that the left ventricle provides systemic output. After the intraventricular baffle procedure electrophysiologic irregularities are occasionally seen, although not as frequently as after the intraatrial baffle procedure.[20] Because noninvasive evaluation does not predict the degree of residual disease, we suggest cardiac catheterization for all patients and advise reoperation when it is hemodynamically indicated.

In spite of the problems associated with the intraventricular baffle procedure, we believe that the overall improvement outweighs the risks of the procedure. Symptoms have been alleviated and hemodynamic status improved in all of our patients, and the younger patients have achieved a significant augmentation of growth.

Addendum

Since this report was submitted, Patients 3 and underwent recatheterization 5.8 and 5.9 years, respectively, after operation. In both patients, right ventricular pressures were at systemic levels or higher, as a result of obstruction in the external conduits. Both successfully underwent conduit replacement, but Patient 3 had a sudden unexplained death 4 months after reoperation.

Idiopathic Recurrent Sustained Ventricular Tachycardia in Children and Adolescents

VICTORIA L. VETTER, MD
MARK E. JOSEPHSON, MD, FACC*
LEONARD N. HOROWITZ, MD, FACC†

Philadelphia, Pennsylvania

The electrophysiologic characteristics of recurrent sustained ventricular tachycardia were studied in seven pediatric patients. The mechanisms of the ventricular tachycardia were evaluated using programmed electrical stimulation. Ventricular tachycardia could be reproducibly initiated in two patients and terminated in one patient in the basal state. It could be initiated in one additional patient and terminated in two additional patients after administration of a type IB drug. In four patients, ventricular tachycardia could not be initiated or terminated by programmed electrical stimulation. The site of origin of the ventricular tachycardia determined by catheter endocardial mapping was the right ventricular outflow tract in four patients, the interventricular septum in two patients and the inferior left ventricle in one patient. The ventricular tachycardia more frequently had an automatic than a reentrant mechanism, and originated more often in the right than in the left ventricle; it was not frequently associated with structural heart disease in this group of patients.

Ventricular tachycardia is an uncommon arrhythmia in children and adolescents and little information is available regarding its electrophysiologic characteristics or mechanisms. In adult patients, the mechanisms of recurrent sustained ventricular tachycardia have recently been studied with programmed electrical stimulation and activation mapping.[1–7] This study describes the electrophysiologic characteristics of recurrent sustained ventricular tachycardia in a group of pediatric patients.

Methods

Study Patients

Seven patients with recurrent sustained ventricular tachycardia were evaluated utilizing programmed electrical stimulation and catheter endocardial mapping (Table I). Of this group, six were male and one female. The age at documentation of the arrhythmia ranged from 5 to 18 years (mean ± standard deviation 12.3 ± 6) and the age at electrophysiologic study ranged from 7 to 21 years (mean 14.9 ± 6).

The diagnosis of ventricular tachycardia was made using standard electrocardiographic criteria[8] and confirmed in all cases by intracardiac recording during the arrhythmia demonstrating (1) the absence of His bundle deflection consistently preceding ventricular depolarization (seven patients), and (2) atrial capture normalizing the QRS configuration (five patients).

All seven patients had recurrent spontaneous episodes of ventricular tachycardia that were sustained for minutes to days with each patient having at least four spontaneous episodes of tachycardia before the electrophysiologic study. Only patients who fulfilled these criteria were included in this study. The patients with only short (less than five ventricular premature depolarizations) nonsustained runs of ventricular tachycardia were not included. In the 4 year interval during which the patients were studied, only three pediatric patients with congenital heart disease and recurrent sustained ventricular tachycardia were seen and studied. Findings in two of these patients who had correction of tetralogy of Fallot are reported elsewhere. The third patient had idiopathic hypertrophic subaortic stenosis.

TABLE 1

Clinical Data in Seven Cases

Case	Sex	Age of Patient (yr)		Cardiac Diagnosis	ECG	Spontaneous Ventricular Tachycardia		
		At Onset	At Study			Configuration	Axis (°)	CL (ms)
1	M	7	7	None	WNL	LBBB	+75	330
2	F	7	8	None	WNL	LBBB	+90	480
3	M	5	10	None	WNL	LBBB	−60	440
4	M	16	18	None	WNL	RBBB	−100	360
5	M	18	22	None	IRBBB, LAH, 1° AVB	LBBB	+90	400
6	M	17	22	CAA	SB, IACD, IRBBB	RBBB	−60	460
7	M	16	17	None	WNL	RBBB	−30	400

AVB = atrioventricular block; CAA = coronary artery anomaly; CL = cycle length; ECG = electrocardiographic findings; IACD = intraatrial conduction delay; IHSS = idiopathic hypertrophic subaortic stenosis; IRBBB = incomplete right bundle branch block; LAH = left anterior hemiblock; LBBB = left bundle branch block; RBBB = right bundle branch block; SB = sinus bradycardia; WNL = within normal limits.

The resting electrocardiogram was normal in five patients and revealed incomplete right bundle branch block in two patients, with first degree atrioventricular (A-V) block in one. No patient had a prolonged Q-T interval or preexcitation.

Hemodynamic and angiographic catheterization studies were performed in all patients. Six patients had completely normal studies and one patient had anomalous origin of the right coronary artery from the left aortic cusp with no hemodynamic abnormality.

Electrophysiologic Studies

Studies were performed in the postabsorptive state after written informed consent had been obtained. Three patients were sedated with Nembutal® (4 mg/kg) and morphine sulfate (0.15 mg/kg). The remaining patients received no sedation. Three to six electrode catheters were inserted percutaneously or by cutdown and positioned using biplane fluoroscopy. The number of recording sites varied but usually included the high right atrium; the left atrium or coronary sinus; the A-V junction at the His bundle site; the right ventricle at the apex, septum, inflow, free wall and outflow tract; and the left ventricle at the apex, septum, lateral wall and base. Standard quadripolar electrode catheters with 1 cm interelectrode distance (USCI, Billerica, Massachusetts) were used to record and stimulate from a specific site. A tripolar catheter was used to obtain the His bundle electrogram.

Stimulation was performed using a specially designed programmable stimulator and an optically isolated constant current source. The stimuli were rectangular pulses 1 ms in duration at twice diastolic threshhold (0.75 to 2 mA). Intracardiac recordings from several sites were simultaneously recorded with three surface electrocardiographic leads and time lines. Intracardiac electrograms were filtered at 40 to 500 hertz. The data were stored on magnetic tape and later retrieved on photographic paper at speeds of 150 to 400 mm/s.

Protocol for programmed stimulation: Ventricular tachycardia, either induced or spontaneous, was present during the electrophysiologic study in all patients.

The following protocol of programmed stimulation was used in each patient:

1. Atrial pacing at incremental rates (cycle length 600 to 250 ms).
2. Premature atrial stimuli during sinus rhythm or atrial pacing, or both.
3. Ventricular pacing at incremental rates (cycle length 750 to 250 ms).
4. Premature ventricular stimuli during sinus rhythm or ventricular pacing, or both. If one premature ventricular stimulus (S_2) scanning from late diastole to ventricular refractoriness did not initiate ventricular tachycardia, scanning with a second premature stimulus (S_3) was then employed. Double premature stimuli (S_2, S_3) were introduced starting at an S_1-S_2 interval 50 to 100 ms longer than the ventricular effective refractory period with the S_2-S_3 interval equal to the S_1-S_2 interval. The S_2-S_3 interval was shortened, and when S_3 failed to evoke a V_3, the S_1-S_2 interval was decreased until S_3 could evoke a response or ventricular tachycardia. This method was used until both S_2 and S_3 reached refractoriness. Stimulation was performed at the right ventricular apex in all patients. In addition, stimulation was performed in the right ventricular outflow tract (six cases) and the left ventricle (seven cases).
5. During ventricular tachycardia, programmed single or double ventricular extrastimuli and rapid ventricular pacing were used in an attempt to terminate the arrhythmia. The extrastimuli were introduced from several different sites including the left ventricle.

Endocardial mapping: Endocardial catheter mapping was performed using one or more 6 French ventricular catheters as exploring electrodes. The mapping sites included fixed sites usually consisting of the A-V junction, the left atrium or the coronary sinus and the high right atrium. The catheter in the right ventricular apex was left in a stable position whenever possible as a reference electrode. The additional mapping sites included the mid septum, anterior wall, outflow tract, lateral inflow tract of the right ventricle and the septum, apex, anterior and lateral walls and inferobasal area of the left ventricle. Two reference points were utilized: one, the earliest onset of the QRS complex in any of the recorded electrocardiographic leads, and the other, a ventricular electrogram recorded from a fixed ventricular site (A-V junction or right ventricular apex). The interval measurement was taken at the point at which the most rapid deflection crossed the baseline,[9,10] using the mean value of six consecutive beats. The earliest site of activation during tachycardia was considered the site of origin of the tachycardia.

Response to antiarrhythmic drugs: This was determined in all patients. The study included the intravenous administration of one or more of the following drugs: (1) lidocaine, 1

TABLE II

Electrophysiologic Data in Seven Cases

Case	A-H	H-V	$ERP_{600}RV$	$ERP_{600}LV$	Induced Ventricular Tachycardia	
					Configuration	CL (ms)
1	125	30	250	260	LBBB	350
2	65	40	180	180	...	...
3	50	90	220	235	...	...
4	85	42	240	240	RBBB	350
5	78	45	190	185	...	...
6	...	...	235	240	RBBB	460
7	...	...	...	...	...	...

CL = cycle length; $ERP_{600}LV$ = effective refractory period of the left ventricle at a cycle length of 600 ms; $ERP_{600}RV$ = effective refractory period of the right ventricle at a cycle length of 600 ms; LBBB = left bundle branch block; RBBB = right bundle branch block.

to 2 mg/kg at 25 mg/min; (2) phenytoin, 5 to 10 mg/kg at 20 mg/min; and (3) procainamide, 10 to 15 mg/kg at 50 mg/min. Levels of phenytoin or procainamide were obtained at the time of demonstrated electrophysiologic effect. Programmed stimulation was repeated immediately on completion of the drug infusion.

Criteria for reentrant versus automatic tachycardia: The criteria used in the present study to define reentrant tachycardia have been discussed by Wellens et al[2,3] and include (1) initiation of tachycardia during cardiac pacing by one or two premature beats within a well defined and reproducible zone of coupling intervals (echo zone); (2) termination of tachycardia by one or two premature stimuli within a well defined and reproducible zone of coupling intervals; and (3) prolongation of the interval from stimulus to first complex of the tachycardia with increasing prematurity of the initiating stimulus.

The criteria used to define automatic tachycardia have been described by Goldreyer et al.[11] *and include:* (1) initiation of tachycardia in the absence of any relation to timing of the premature stimulus; (2) initiation of tachycardia by an impulse falling late in diastole outside the relative refractory period of the ventricle; and (3) absence of reproducible termination of tachycardia by programmed electrical stimulation.

Results

Basal electrophysiologic data: A-H and H-V intervals could be obtained in five patients (Table II). In one patient with azygous continuation of the inferior vena cava, a His bundle deflection could not be obtained because of difficulty with catheter manipulation. In a second patient, A-H and H-V intervals could not be obtained because of incessant ventricular tachycardia throughout the study. The A-H intervals were normal in the five patients. The H-V intervals were normal for age in four patients and prolonged in one patient who had intermittent infra-His block (Case 3).

Sinus nodal function was normal as determined by sinus nodal recovery time[12] and sinoatrial conduction time in six patients. One patient had severe sinus nodal dysfunction. Atrial function as determined by the atrial refractory period[13] was normal in all patients.

A-V nodal function was normal in six patients. Wenckebach cycle lengths were less than 400 ms in each of these patients. One patient exhibited infra-His block at a cycle length of 350 ms.

Electrocardiographic characteristics of ventricular tachycardia: The cycle length of the spontaneous ventricular tachycardia was 330 to 480 ms (mean 410 ± 54). In five of the patients who had spontaneous ventricular tachycardia during the study, the first ventricular tachycardia complex, which was similar in configuration to the subsequent tachycardia complexes, followed the last sinus complex with a relatively long R-R interval (greater than 75 percent of the R-R interval). Two patients had fusion complexes and all patients had A-V dissociation during ventricular tachycardia.

Initiation of ventricular tachycardia: Ventricular tachycardia could be initiated reproducibly in two patients in the basal state (Table III), by rapid ventricular pacing in one (Case 6) and by single ventricular stimuli and rapid ventricular pacing in the other patient (Case 4). In an additional patient (Case 1), the tachycardia could not be initiated in the basal state but could be initiated by single ventricular premature stimuli after administration of lidocaine (Fig. 1).

Ventricular tachycardia could not be initiated in the remaining four patients by any method utilized including rapid atrial and ventricular pacing, and single

TABLE III

Initiation and Termination of Ventricular Tachycardia in Seven Cases

Case	Mode of Initiation			Mode of Termination		
	1VPD	2VPD	VP	1VPD	2VPD	VP
1	+	...	...	+	...	+
2	−	−	−	−	−	−
3	−	−	−	−	−	−
4	+	...	+	+	...	+
5	−	−	−	−	−	−
6	−	−	+	+	...	+
7	−	−	−	−	−	−

+ = successful; − = unsuccessful; VP = ventricular pacing; VPD = ventricular premature depolarization.

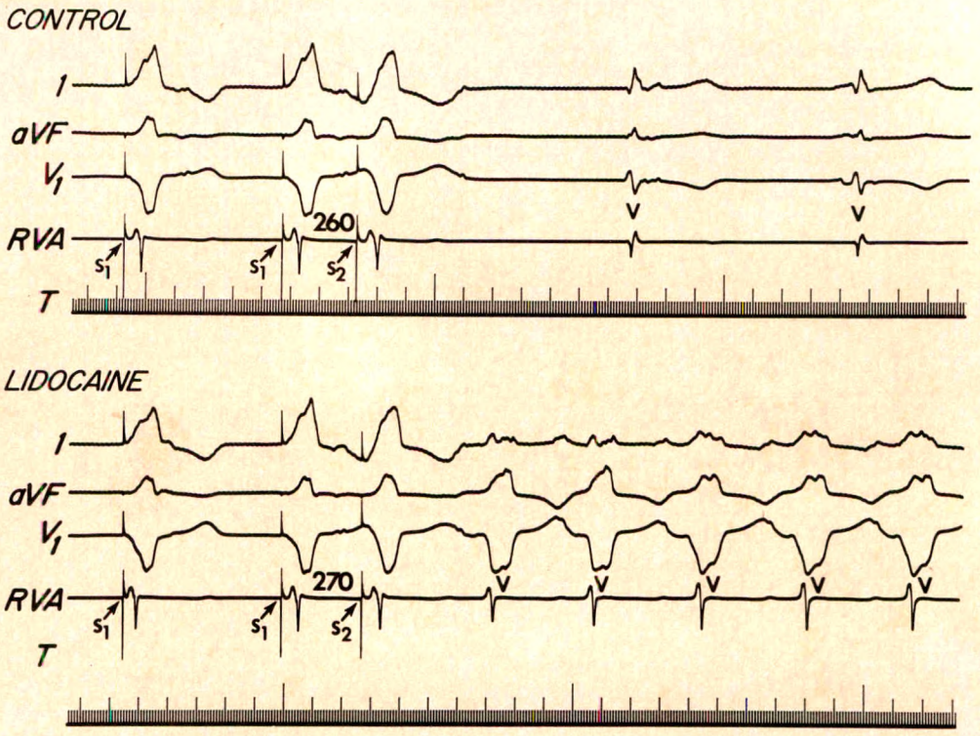

FIGURE 1. Patient 1. Initiation of ventricular tachycardia only after lidocaine infusion. In both panels, electrocardiographic leads I, aVF and V_1 are shown with a right ventricular apical (RVA) electrogram and 10 ms time (T) lines. Stimuli are indicated by **arrows.** In the **upper panel** during control conditions, a single premature stimulus (S_2) delivered during ventricular pacing at a cycle length of 550 ms (S_1-S_1) failed to initiate ventricular tachycardia. No other stimulation protocol initiated ventricular tachycardia during control conditions. After an infusion of lidocaine (30 mg) **(lower panel),** a single premature stimulus initiated ventricular tachycardia reproducibly. After elimination of lidocaine, ventricular tachycardia was no longer inducible by programmed stimulation.

and double ventricular premature stimulation both in sinus rhythm and during ventricular pacing from multiple sites including the right ventricular outflow tract, right ventricular apex and left ventricular apex.

Response to programmed stimulation during ventricular tachycardia: Ventricular tachycardia could be terminated reproducibly in one patient (Case 6) by single ventricular premature stimuli or rapid ventricular pacing. In one patient (Case 1), the tachycardia could not be terminated in the basal state but could be terminated by single ventricular premature depolarizations after administration of lidocaine (Fig. 2). In one additional patient (Case 4), the tachycardia could be terminated intermittently in the basal state but at other times required the administration of phenytoin for reproducible termination.

In the remaining four patients, ventricular tachycardia could not be terminated by electrical stimulation either before or after drug administration. In these four patients, ventricular stimulation did not terminate tachycardia but reset it, resulting in a pause followed by a gradual warm-up of tachycardia (Fig. 3).

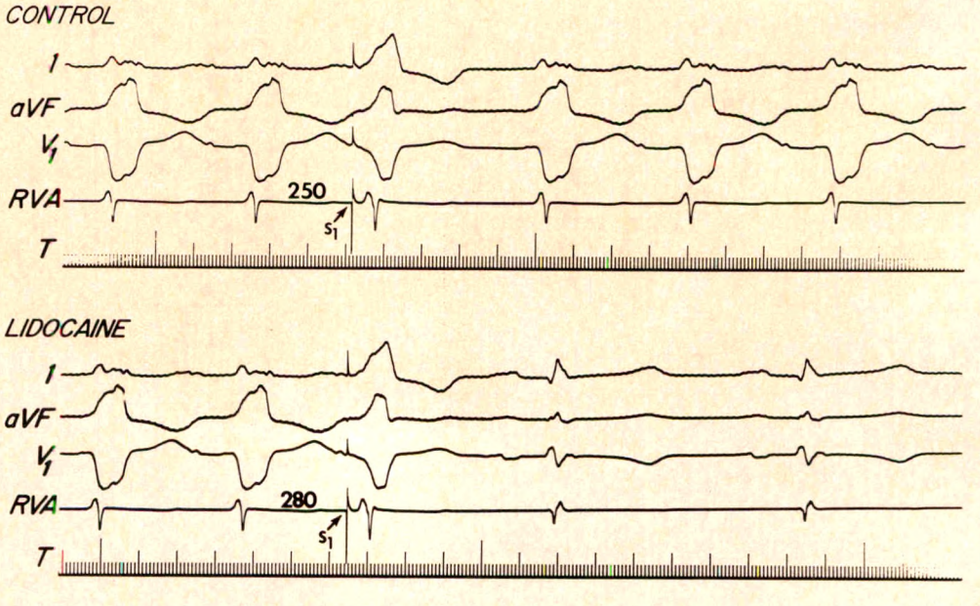

FIGURE 2. Patient 1. Termination of ventricular tachycardia by programmed stimulation after administration of lidocaine. The format in each panel is the same as in Figure 1. In the **upper panel,** a single programmed extrastimulus (S_1) delivered at a coupling interval of 250 ms failed to terminate ventricular tachycardia. This was the shortest interval at which a single extrastimulus captured the ventricles. No other stimulation technique was capable of terminating ventricular tachycardia. After lidocaine infusion **(lower panel)** a single extrastimulus (S_1) at a coupling interval of 280 ms terminated ventricular tachycardia. After metabolism of lidocaine, programmed stimulation failed to terminate ventricular tachycardia.

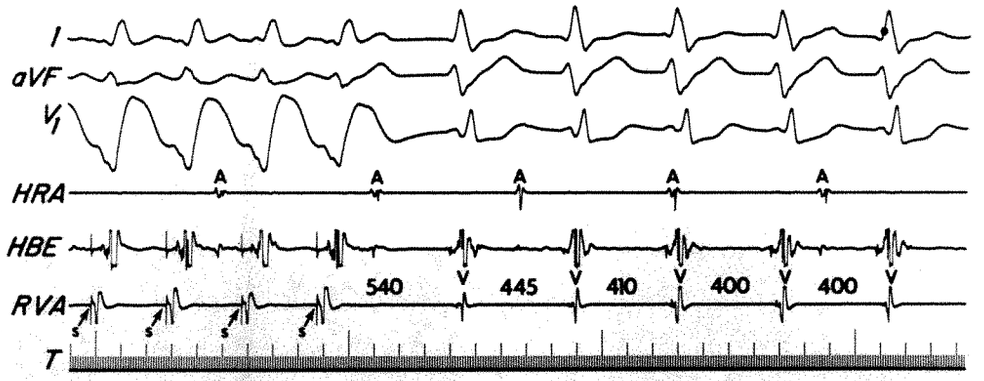

FIGURE 3. Patient 7. Demonstration of "warm-up" of ventricular tachycardia after overdrive pacing. Electrocardiographic leads I, aVF and V_1 are displayed with bipolar electrograms recorded in the high right atrium (HRA), His bundle area (HBE) and right ventricular apex (RVA) and 10 ms time (T) lines. Pacing stimuli (s) are indicated by **arrows** and the interelectrogram intervals are indicated in milliseconds. Right ventricular pacing at a cycle length of 300 ms was begun during ventricular tachycardia (not shown) and discontinued after 30 seconds at the fourth stimulus. Ventricular tachycardia persisted. Note that the tachycardia cycle length progressively discussed over four cycles until it returned to the control cycle length of 400 ms present before pacing.

Atrial pacing in five patients resulted in ventricular capture converting the QRS complex to a supraventricular configuration without termination of ventricular tachycardia. Another patient had spontaneous sinus captures without termination of arrhythmia. Ventricular pacing could capture the ventricles in all patients without interrupting ventricular tachycardia.

Endocardial mapping and sites of origin: The QRS configuration of the ventricular tachycardia was right bundle branch block in three patients and left bundle branch block in four (Fig. 4). The site of origin of ventricular tachycardia was the right ventricular outflow tract in the four patients with left bundle branch block configuration (Table IV). The configuration of these ventricular tachycardias originating in the right ventricular outflow tract was similar in these four patients. The site of origin in the three patients with right bundle branch block configuration was the inferobasal wall of the left ventricle, the mid right ventricular septum and the mid left ventricular septum respectively (Fig. 5). Confirmation of mapping data was obtained by pacing from the site of origin, which produced a QRS configuration similar to that of the spontaneous ventricular tachycardia.

Discussion

Ventricular tachycardia is an uncommon arrhythmia in childhood, although our recent experience suggests that it is more common than is generally appreciated

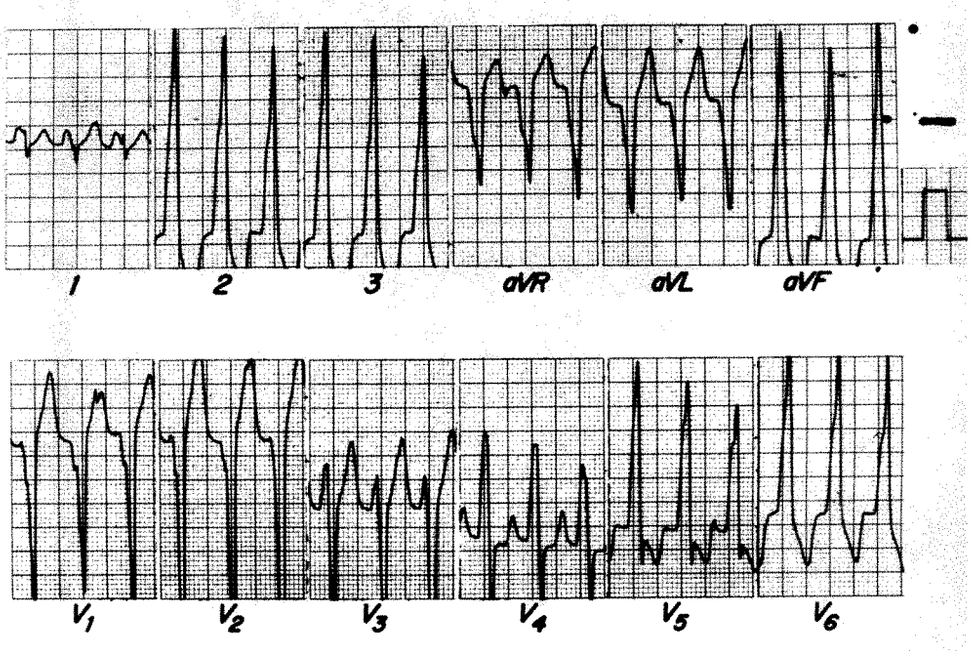

FIGURE 4. Patient 5. Electrogram during ventricular tachycardia. It is typical of the ventricular tachycardias with a left bundle branch block configuration observed in this group of patients. The right precordial leads show an rS or QS pattern, and the limb leads show an inferior axis with all monophasic R waves in leads II, III and aVF.

TABLE IV

Site of Origin of Ventricular Tachycardia in Seven Cases

Case	Configuration Mapped	Site of Origin
1	LBBB	RVOT
2	LBBB	RVOT
3	LBBB	RVOT
4	RBBB	RIVS
5	LBBB	RVOT
6	RBBB	LV, inferobasal
7	RBBB	LIVS

LBBB = left bundle branch block; LIVS = left endocardial surface of the interventricular septum; LV = left ventricle; RBBB = right bundle branch block; RIVS = right endocardial surface of the interventricular septum; RVOT = right ventricular outflow tract.

Although various reports of ventricular tachycardia in children have attributed the arrhythmia to congenital or acquired heart disease,[14,15] myocarditis,[16] metabolic disturbances,[17] cardiac catheterization or surgery[18] or drug toxicity, other reports have found no known etiology or structural heart disease.[19,20] The findings in our series of seven patients are consistent with the studies in which structural heart disease is uncommon. One of our patients had a coronary arterial abnormality of undetermined significance, whereas six of the seven patients had completely normal angiographic and hemodynamic studies.

Ventricular tachycardia in children versus adults: Limited electrophysiologic data are available concerning ventricular arrhythmias in children.[21–23] No activation studies or mapping data during ventricular tachycardia have been reported. Early reports of ventricular tachycardia in children provided clinical information including abbreviated electrocardiographic recordings. Many of the electrocardiograms during ventricular tachycardia in the earlier reports bear a striking resemblance to each other. The most common QRS configuration has been left bundle branch block pattern of tachycardia, usually occurring in children with a normal heart. The right bundle branch configuration was reported primarily in children with left ventricular structural abnormalities, most notably cardiac tumors.[24] In contrast to findings in the pediatric age group, ventricular tachycardia in adults usually occurs in association with structural heart disease. Coronary artery disease with or without a ventricular aneurysm is the most common abnormality.[6,25,26] Arrhythmogenic right ventricular dysplasia with ventricular tachycardia has also been described in adults.[27] There are a few reports of adults with no heart disease with "idiopathic" ventricular tachycardia, but these reports represent less than 10 percent of adult patients with ventricular tachycardia.[20,28–30] The presence of structural heart disease and the right bundle branch pattern of ventricular tachycardia in adults strongly contrasts with the absence of structural heart disease and the left bundle branch block pattern of ventricular tachycardia in children.

Endocardial catheter mapping of the ventricles in adults has been reported.[7] The most common site of origin of ventricular tachycardia was the left ventricle, particularly in an aneurysm of the left ventricle when this was present. In contrast, the most common site of origin of ventricular tachycardia in our children was the right ventricle, especially the right ventricular outflow tract.

Reentrant tachycardia in children versus adults: The mechanisms of ventricular tachycardia in adults have been studied by several investigators.[1–7] Wellens et al.[2,3] suggested that initiation and termination of the arrhythmia by stimulation and an inverse relation of the initiating coupling interval and the interval of the first complex of the tachycardia indicate a reentrant mechanism. On the basis of these criteria, 70 to 95 percent of adult patients with ventricular tachycardia have reen-

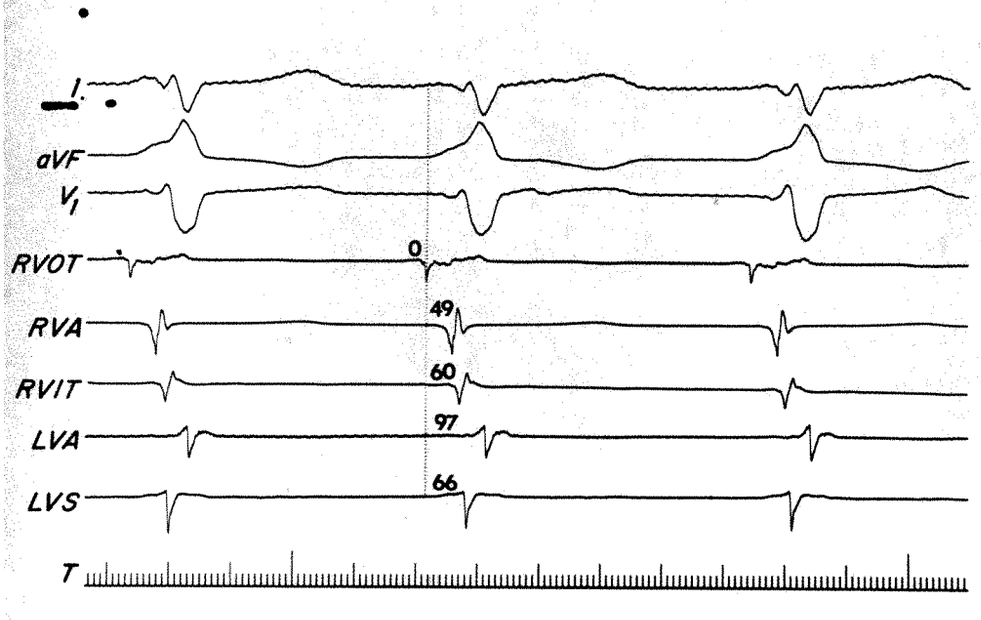

FIGURE 5. Patient 2. Ventricular endocardial mapping during ventricular tachycardia. Electrocardiographic leads I, aVF and V_1 are shown with bipolar electrograms recorded at the right ventricular outflow tract (RVOT), the right ventricular apex (RVA), the right ventricular inflow tract (RVIT), the left ventricular apex (LVA) and the left ventricular septum (LVS) and 10 ms time (T) lines. The **dotted line** indicates the onset of the QRS complex and the numbers indicate activation times (ms) measured from the onset of the QRS complex. Ventricular tachycardia was present and the earliest electrical activity was recorded in the right ventricular outflow tract. The earliest left ventricular electrograms were recorded on the left side of the intraventricular septum. No other site in this patient was activated earlier than the right ventricular outflow tract.

trant ventricular tachycardia.[31] A few investigators[4,32] have not been able to confirm these results, particularly in patients with a very recent myocardial infarction. Others[33] have suggested that programmed electrical stimulation may also induce an unusual type of automatic tachycardia caused by triggered automaticity. This type of automaticity, in contrast to the usual type of enhanced phase 4 automaticity, requires an initiating stimulus that triggers a self-sustaining automatic discharge. To date, no evidence of triggered automaticity has been shown in human ventricular tissue.

Ventricular tachycardia in our patients was infrequently initiated and terminated by programmed electrical stimulation. Tachycardia fulfilled the criteria for reentry in only two patients. In one additional patient, the criteria for reentry were fulfilled only after administration of drugs. The significance of initiation and termination only after administration of drugs is unclear. The tachycardias in the other four children, in contrast, did not meet the criteria for a reentrant mechanism and had characteristics of automatic ventricular tachycardia as described by Goldreyer et al.[11] Thus, less than half of the children (three of seven) had studies suggesting a reentrant mechanism, whereas approximately 90 percent of adult patients fulfill the criteria for reentrant ventricular tachycardia.

Clinical implications: The differences in the frequency of the reentrant mechanism of ventricular tachycardia in children and adults and the differences in the anatomic substrates necessitate differences in evaluation and therapy. The presence of automatic ventricular tachycardia or lack of a reproducible initiation of tachycardia makes the laboratory evaluation of pharmacologic therapy utilizing electrophysiologic study, as was recently described in adults, much less useful in most children than in adults.[32,34–37] This method of evaluation is only useful in the presence of a reentrant ventricular tachycardia that can be reproducibly initiated and terminated.

Clinical Course of Cardiovascular Involvement in the Mucocutaneous Lymph Node Syndrome

Relation Between Clinical Signs of Carditis and Development of Coronary Arterial Aneurysm

SATOSHI HIRAISHI, MD*

Kanagawa Prefecture, Japan

Seventy-nine patients with mucocutaneous lymph node syndrome were evaluated prospectively by clinical examination, electrocardiography, chest radiography, M mode and two dimensional echocardiography and thallium-201 myocardial scanning. Serial changes were categorized according to the duration of illness: stage I (1 to 10 days), stage II (11 to 20 days), stage III (21 to 30 days), stage IV (31 to 60 days) and stage V (61 days to 40 months). The presence of myocarditis in stages I and II was suggested in 40 of 79 patients (50.6 percent) by electrocardiographic, echocardiographic, radiographic and clinical abnormalities. Myocarditis was accompanied by pericarditis in six patients and by both endocarditis and pericarditis in one patient. These signs of inflammation were resolved by stage III in all but three patients with electrocardiographic abnormalities. In the active stage, large coronary arterial lesions were suspected only because of an abnormal spherical echo-free space in the region of the coronary arteries on two dimensional echocardiograph as well as electrocardiographic evidence of deep Q waves in leads II, III and aVF. One or more coronary aneurysms developed in 11 patients, primarily in stage II; regression of the aneurysm was noted in 5 of these patients during stages III, IV and V. Aneurysm regression demonstrated by angiography did not correlate with echocardiographic changes in aneurysm size in one patient. Moreover, the occurrence of coronary aneurysm did not correlate with the presence of signs of carditis, because the frequency of carditis was the same in patients with and without aneurysm.

The mucocutaneous lymph node syndrome (Kawasaki's disease) is a clinical entity consisting of high fever, mucocutaneous involvement and cervical lymphadenopathy that affects infants and young children.[1] The acute inflammatory features consist of angiitis with involvement of multiple organ systems.[2] It has been suggested[2–7] that the pathologic changes are indistinguishable from those observed in infantile periarteritis nodosa.[2–4] Although this syndrome is predominantly found in Japan, it has become increasingly recognized in other countries.[5–10] Carditis and coronary arterial lesions have frequently been demonstrated in association with mucocutaneous lymph node syndrome.[11–13] However, the natural history of carditis and coronary arterial aneurysms is unclear. Furthermore, to our knowledge, there are no clinical data that evaluate serially the relation between carditis and coronary aneurysms. Thus the present study was undertaken to determine the natural history of the cardiovascular aspects of mucocutaneous lymph node syndrome and particularly, to evaluate the relation between signs of carditis and the development of coronary arterial abnormalities.

Methods

Clinical criteria and diagnosis: Seventy-nine patients admitted to Kitasato University Hospital between November 1976 and November 1979 were evaluated prospectively. There were 53 male and 26 female patients aged 3 months to 10 years (mean 2.7 years). The diagnosis of mucocutaneous lymph node syndrome was made on the basis of criteria proposed in 1972 by the Japanese Mucocutaneous Lymph Node Syndrome Research Committee.[14]

The clinical course was categorized according to the duration of illness as follows: stage I (1 to 10 days), stage II (11 to 20 days), stage III (21 to 30 days), stage IV (31 to 60 days) and stage V (61 days to 40 months). The onset of illness was defined as the day of the first diagnostic symptom. The duration of fever, heart sounds, heart murmur, friction rub and erythrocyte sedimentation rate were evaluated serially. Electrocardiography, chest radiography and M mode and two dimensional echocardiography were performed in all patients on admission (stage I) and at least once a week during stages I through III of the disease and occasionally through stage IV. Thallium-201 myocardial scanning was performed in 48 patients one to three times during the course of their illness. The diagnosis of carditis was entertained when clinical signs such as gallop rhythm, heart murmur, friction rub and laboratory signs of an abnormal electrocardiogram, radiogram and echocardiogram were observed.[15] The major criterion for angiography was two dimensional echocardiographic detection of coronary aneurysms. Other criteria included an abnormally high score on the table devised by Asai et al.[11] By these criteria, angiography was indicated in only 15 patients between 35 days and 5 months (mean 1.8 months) after the onset of the disease. Four patients underwent follow-up coronary angiography 1 to 3 years after the initial evaluation.

The following therapeutic programs were employed: (1) Antibiotic agents (aminobenzyl penicillin or cephaloridine, 100 mg/kg per day) were administered until bacterial infection was excluded. (2) Aspirin (30 to 50 mg/kg per day) was given until clinical evidence disappeared and the erythrocyte sedimentation rate returned to normal. (3) Glucocorticoid (prednisolone, 2 mg/kg per day), depending on the clinical gravity of the disease, was given until cardiac signs or prolonged fever disappeared. (4) Patients with coronary arterial lesions received aspirin (30 mg/kg per day) or warfarin (0.1 to 0.2 mg/kg per day) adjusted to 15 to 30 percent by Thrombotest (Quick prothrombin test), or both, during the existence of large coronary lesions.

Electrocardiography: Electrocardiograms were evaluated for changes compatible with myocarditis or pericarditis such as (1) P-R interval prolongation of 0.17 second or greater; (2) prolonged corrected Q-T interval (Q-Tc) of 0.425 second or greater; (3) R wave in V_6 of 0.6 mV or less; (4) R wave in lead V_1 of 0.4 mV or less; (5) amplitude of P wave of 0.25 mV or greater; (6) duration of P wave of 0.08 second or greater; (7) S-T segment depression of 0.1 mV or greater for 0.06 second or greater below the baseline; (8) S-T segment elevation of 0.2 mV or greater (except for right precordial leads); (9) T wave in lead V_6 of 0.1 mV or less (age less than 6 months), T wave in lead V_6 of 0.2 mV or less (age 6 months or greater); (10) evidence of myocardial ischemia or infarction, such as Q/R ratio of 0.3 or greater, increasing Q waves or ST-T changes or all three; (11) standard criteria for left or right ventricular hypertrophy; and (12) various arrhythmias.[15–17]

Chest radiography: The cardiothoracic ratio was measured serially on chest radiograms. Cardiomegaly was suggested by a cardiothoracic ratio greater than 55 percent or an increase of more than 5 percent in serial films, or both.[18]

M mode echocardiography: Echocardiograms were obtained with a commercially available ultrasonoscope (ALOKA SSD 200 or 100) (ALOKA Company Ltd., Tokyo) utilizing a 3.5 or 2.25 megahertz nonfocused transducer. The transducer was placed at the third or fourth intercostal space at the left parasternal border. The M mode scan from the aortic root to the apex of the left ventricle was recorded on Polaroid® film or by strip chart recorder. Left ventricular function was evaluated by calculation of percent fractional shortening, the ratio of posterior wall to septal excursion and B-B′ formation[19] on the anterior mitral leaflet. The echocardiogram was also assessed for pericardial effusion. The echocardiographic indexes of left ventricular performance were compared with normal values for children established in our laboratory, which are similar to those reported by others for normal children and adults.[20–22] Abnormal indexes were defined by a percent fractional shortening of 32 percent or less or a ratio of posterior wall to septal excursion of 3.5 or greater or less than 1.0. Pericardial effusion was diagnosed by visualizing separation of the epicardium from the pericardium in both systole and diastole.[23]

Two dimensional echocardiography: This procedure was performed using an electronic linear scanner with a 3.5 megahertz, 60 element transducer adjusted to focus at 4 and 7 cm (ALOKA SSD 200). Visualization of the main coronary arteries was accomplished in the manner reported previously by our group.[24] The diagnosis of coronary arterial aneurysm was made by visualization of a spherical or fusiform shape of the proximal portion of the main coronary arteries. Furthermore, a few days after initial study, patients with ultrasonic evidence of coronary aneurysm were reevaluated to establish the reproducibility of the echocardiographic findings.

Thallium-201 myocardial scanning: Myocardial images were obtained utilizing a high resolution scintillation camera (Pho Gamma HP and LFOV Gamma Camera) (Searle Company, Chicago) and a 140 keV parallel hole collimator or converging collimator, within 10 minutes of intravenous injection of 0.5 to 1 mCi of thallium-201 chloride. The images were recorded in the anteroposterior, left lateral and 30° left anterior oblique projections. Interpretation was undertaken without prior knowledge of clinical findings. A consistent decrease in myocardial uptake observed in at least two views was interpreted as abnormal.[25]

Left heart catheterization and angiography: After left ventricular pressures were recorded, left ventricular and aortic cineangiography were performed in the standard manner. Three patients underwent selective coronary angiography. Ejection fraction was calculated by the single plane area-length method.[26] Asynergy was assessed by the criteria of Herman and Gorlin.[27]

Results

Auscultatory signs: A gallop rhythm was audible transiently in stages I and II in 10 patients (12.6 percent). A significant heart murmur suggesting mitral regurgitation was found in only one patient in stage I and disappeared 5 days later. A friction rub was not observed.

Electrocardiography: Electrocardiographic abnormalities consisted of (1) prolongation of the P-R interval in 11 cases (13.9 percent); (2) prolongation of the Q-Tc interval in 18 cases (22.8 percent); (3) low amplitude R wave in lead V_1 or V_6 in 13 cases (16.5 percent); (4) low amplitude T wave in lead V_6 in 12 cases

(15.2 percent); and (5) ST-T wave changes in 8 cases (10.1 percent). Deep Q waves, P wave changes, left ventricular hypertrophy, right ventricular hypertrophy, sinus bradycardia, second degree atrioventricular (A-V) block and premature ventricular complexes each occurred in a small percent of cases. In serial electrocardiograms low amplitude R and T waves appeared in stages I and II and returned to normal by stage III. Abnormal S-T segment changes occurred primarily in stages I and II, and were resolved by stage IV. Transient arrhythmias such as sinus bradycardia (two patients) and second degree A-V block (one patient) were observed in stage II. In contrast, abnormal Q wave patterns (four patients) appeared in stages II and III and persisted to later stages. Of these four patients, one died suddenly in stage V. Premature ventricular complexes were also found in stage III in one patient with deep Q waves (Table I).

Chest radiography: A cardiothoracic ratio greater than 50 percent with an increase of greater than 5 percent in serial films was observed in 16 patients (20.3 percent). Cardiomegaly with a cardiothoracic ratio greater than 60 percent occurred in only two patients. These findings were seen in stages I and II with resolution by stage III (Table I).

M mode echocardiography: The abnormalities observed included (1) percent fractional shortening of 32 percent or less in 15 patients (19.0 percent), of whom 10 had shortening of less than 28 percent; (2) posterior wall to septal excursion ratio greater than 3.5 in 4 patients (5.1 percent); and (3) pericardial effusion in 7 patients (8.8 percent). No patient had either a posterior wall to septal excursion ratio of less than 1.0 or B-B′ formation. Each of the six patients with pericardial effusion had reduced percent fractional shortening. Abnormal echocardiographic indexes were observed in stages I and II and resolved by stage III (Table I).

Two dimensional echocardiography: Satisfactory visualization of the left main coronary artery was achieved in 75 patients (94.9 percent). The proximal portion of the right coronary artery was visualized well in only 14 patients (17.7 percent). Spherical or fusiform patterns, or both, in the main coronary arteries were observed in eight patients during stage II and in three during stage III. These patterns disappeared in two patients during stage III, in one patient during stage IV and in two patients during stage V. Echographic evidence of coronary arterial aneurysms persisted to stage V in seven patients. Among these seven patients, angiography imaged multiple aneurysms of the right and left coronary arteries in four, and a single aneurysm of the proximal portion of the left coronary arteries in three. Of the three patients in whom echographic evidence of left coronary arterial aneurysm disappeared by stage III or IV (Fig. 1), one had normal coronary arteries on aortography at the time of normal echographic examination. In four patients, initial and subsequent angiography confirmed the two dimensional echocardiographic evidence of coronary arterial aneurysms. The findings remained unchanged in two of the four pa-

TABLE I

Serial Changes of Abnormal Findings of Four Clinical Indexes (M mode echocardiogram, chest radiogram, gallop rhythm and heart murmur)

Indexes	Patients (n)	Appearance of Abnormal Findings (patients [n])		Disappearance of Abnormal Findings (patients [n])		
		I	II	III	IV	V

Chest radiography						
Increased CTR	16	12/8	4/6	0/2	...	...
Presence of gallop rhythm	10	6/5	4/4	0/1	...	...
Mitral regurgitant murmur	1	1/1	...	...	...	...
Friction rub	0	0	...	...	...	...

CTR = cardiothoracic ratio; %FS = percent fractional shortening of the left ventricle; PVC = premature ventricular complex; PWe/LSe = ratio of left posterior wall to left septal excursion.

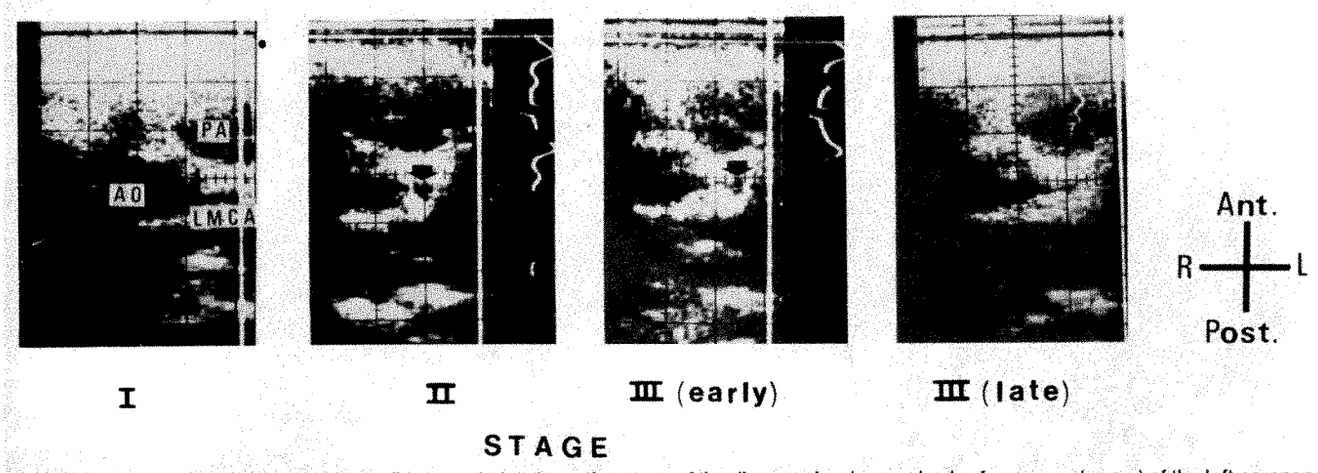

FIGURE 1. Serial two dimensional echocardiograms during the active stage of the disease. An abnormal echo-free space (**arrow**) of the left coronary artery was observed in stage II and disappeared during stage III. Ant. = anterior; AO = aorta; L = left; LMCA = left main coronary artery; PA = pulmonary artery; Post. = posterior; R = right.

tients, whereas evidence of regression was found in the remaining two. In one of the two patients with angiographic evidence of regression, the lesion remained prominent on echocardiography (Fig. 2 and 3). Six of seven patients with normal coronary echograms had normal coronary arteries on angiography. The remaining patient had a small aneurysm in the distal portion of the left anterior descending artery.

Thallium-201 myocardial scanning: Significant perfusion defects were not observed in serial follow-up studies that included eight patients with coronary lesions.

Cardiac catheterization data: In the patients who underwent catheterization, left ventricular end-diastolic pressure ranged from 8 to 18 mm Hg (mean 13) and ejection fraction 57 to 75 percent (average 64). No patient had evidence of left ventricular asynergy or mitral regurgitation.

Correlation of four cardiac indexes: There was a greater incidence of electrocardiographic changes (40.3 percent) than of M mode echocardiographic abnormalities (20.3 percent), cardiomegaly (20.3 percent) or gallop rhythm (12.7 percent) (Fig. 4, left panel). Eighty-one percent of patients with an abnormal echocardiogram, 75.0 percent of those with cardiomegaly and 90.0 percent of those with gallop rhythm had a coexisting abnormal electrocardiogram. Patients with abnormalities of more than one, two or three of the four cardiac indexes made up 50.6 percent (n = 40), 26.6 percent (n = 21) and 13.9 percent (n = 11) of the population, respectively, whereas abnormalities of all four indexes were present in only 5.1 percent (n = 4) (Fig. 4,

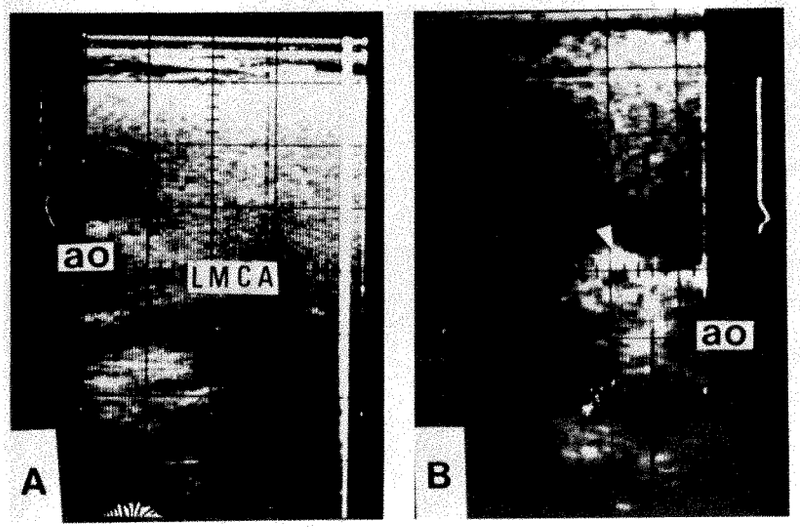

FIGURE 2. A, two dimensional echocardiograms taken 3 years after the onset of the disease, demonstrating regression of a left coronary arterial aneurysm. **B,** although an abnormal echo-free space noted in the stem of right coronary artery (**arrow**) also regressed, its outer wall became thickened and the overall size of the abnormal echo representing the aneurysm was similar to the initial echocardiogram (Fig. 4, Hiraishi et al.[24]). ao = aorta; LMCA = left main coronary artery.

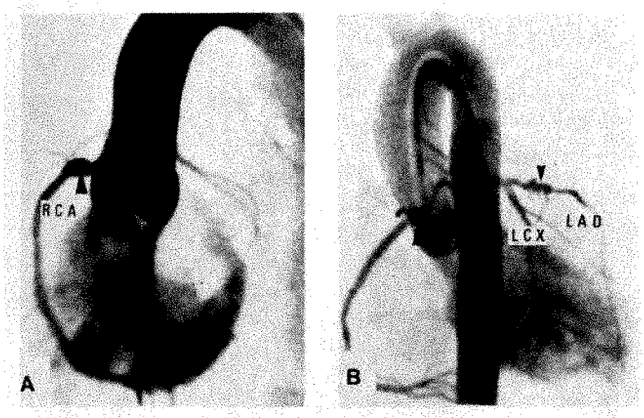

FIGURE 3. Aortograms (**A**, left oblique view; **B**, right oblique view) corresponding to the two dimensional echocardiograms in Figure 2. The regression of both the left and right coronary aneurysms (**arrows**) is observed. The **right arrow** in **B** demonstrates stenosis at the same location of aneurysm formation of the left anterior descending (LAD) coronary artery after 3 years. These angiograms should be compared with those of the initial evaluation (Fig. 4, Hiraishi et al.[24]). LCX = left circumflex coronary artery; RCA = right coronary artery.

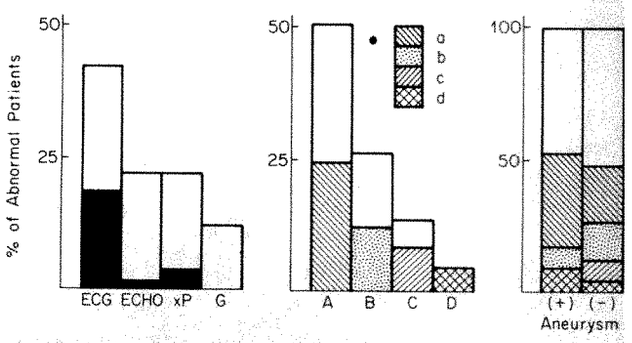

FIGURE 4. Left, percent of abnormal patients among all patients assessed by electrocardiogram (ECG), M mode echocardiography (ECHO), chest radiography (xP) and presence of gallop rhythm (G). **Shaded area** shows percent of patients with only one abnormality. **Middle,** percent of patients with abnormalities of one or more (A), two or more (B), three or more (C) and all four indexes (D). **Shaded areas** indicate percent of patients with abnormalities of one index (a) and two (b), three (c) and four (d) indexes. **Right,** comparison of the incidence of carditis among 11 patients with aneurysm (+) and 68 patients without aneurysm (−). The incidence of carditis is the same in the two groups. **Shaded areas** a, b, c and d are defined in the **middle** panel.

middle panel). Progression and regression of electrocardiographic abnormalities, especially of low amplitude R and T waves and S-T segment changes, correlated closely with progression of abnormal echocardiographic changes, cardiomegaly and gallop rhythm; that is, they appeared during stages I and II and were primarily resolved by stage III. In contrast, deep Q waves occurred in stages II and III and persisted in the later stages. Therefore, carditis was suspected when abnormalities of more than one of four cardiac indexes exclusive of Q waves existed. Because carditis consists of pericarditis, myocarditis and endocarditis, we further evaluated their frequency in this syndrome. Six of seven patients with pericardial effusion also had reduced fractional shortening. Pericardial effusion and reduced fractional shortening were echocardiographic features in the one patient who manifested a murmur of mitral regurgitation. Because these phenomena occurred in a single patient in stage I, pancarditis was very likely. It was therefore suggested that almost all patients with carditis had myocarditis.

Relation between carditis and coronary aneurysm: Six (54.5 percent) of 11 patients with coronary aneurysms had clinical evidence suggesting carditis, compared with 34 (50.0 percent) of 68 patients without coronary aneurysms (Fig. 4, right panel). Thus the frequency of carditis was the same in patients with and without aneurysms.

Other clinical data (Table II): The 79 patients studied were classified into four groups: Group A, 40 patients with carditis only; Group B, 7 patients with only a single coronary aneurysm; Group C, 4 patients with multiple coronary aneurysms; and Group D, 28 patients without significant clinical findings. No significant differences were found in any of the indexes evaluated among groups A, B and D. Group C, however, consisted of younger patients who had a prolonged period of increased erythrocyte sedimentation rate and elevated fever. Careful palpation of peripheral arteries, specifically the axillary and radial arteries, enabled the detection of axillary aneurysms and decreased pulsation of the radial artery in two patients in Group C. No significant difference was found in the duration and frequency of administration of aspirin and antibiotic therapy among the four groups. Corticosteroids were administered to six Group A and B patients with carditis in stages I and II, and three Group C patients

TABLE II
Clinical Data on 79 Patients

during stages III and IV. The duration of steroid therapy varied from 1 to 3 weeks.

Discussion

Carditis

Diagnostic criteria and incidence: Difficulty exists in making the diagnosis of carditis with reasonable reliability in current clinical practice.[15,28] In this study, 43 percent of all patients had electrocardiographic evidence of carditis. This is a rather low incidence rate in light of the electrocardiographic data presented by Asai,[12] which suggested that myocarditis or pericarditis, or both, occurred in almost all patients. Differences seem to be related to criteria utilized in making the electrocardiographic diagnosis. Our study excluded mild relative changes in R and T wave voltage because such changes may reflect fever or other related conditions. In our study, carditis was manifested not only by the electrocardiogram but also by the echocardiogram, the chest radiogram and the presence of gallop rhythm and a heart murmur. If carditis is defined by abnormalities of more than two or three of these four cardiac indexes, the specificity of the diagnosis is enhanced but mild cases with carditis might be overlooked because of a reduction in sensitivity. Of primary importance, serial changes of these findings corresponded. Moreover, we endeavored to correlate the clinical information with previously published pathologic data. In a pathologic report of 13 cases,[29] pericarditis, myocarditis and endocarditis were common in stages I through III in 100, 69 and 54 percent, respectively. Compared with the pathologic data, our clinical indexes showed a lesser incidence of carditis, especially pericarditis and endocarditis. These differences may be related to the sensitivity of the clinical indexes used and differences in populations studied. Of interest, the pathologic findings in patients with myocarditis correlated with the clinical stage.

Myocardial ischemia: A study of endomyocardial biopsies in this disease showed that myocardial changes may be due to ischemic changes caused by arteritis of small arteries.[30] In our echocardiographic studies, diminished septal motion without augmentation of left ventricular posterior wall motion was found in only four patients with carditis during stages I and II. Thallium-201 myocardial scanning showed no distinct decreased uptake. Therefore, it was difficult to detect significant myocardial ischemia in the early stage of the disease. In contrast, increasing deep Q waves without ST-T changes persisted from stage IV through stage V, in four patients, three of whom had coronary aneurysms. None of these patients had significant clinical findings other than abnormal Q waves. Although the most specific indicator of myocardial ischemia, primarily due to large coronary lesions in the active stage, was the presence of deep Q waves, their presence was not a sensitive indicator of aneurysm formation since they were observed in only 3 of 11 patients with aneurysms. Clinicopathologic studies[31] have demonstrated myocardial damage in more than 30 percent of the wall thickness of the left ventricle primarily due to myocardial infarction in patients with deep Q waves without associated ST-T changes. Our data revealed resolution of Q wave abnormalities during 2 years of follow-up study in three of the four patients.

Myocarditis: Our study suggests that abnormal clinical and laboratory findings occurring in stages I and II result from carditis, primarily myocarditis. Even in patients with large coronary lesions, significant clinical findings do not appear in these stages unless severe myocardial ischemia or myocardial infarction is present. To our knowledge, myocardial infarction has rarely been observed in these early stages,[32–34] and clinical and laboratory evidence of infarction such as sudden onset of vomiting, pallor, dyspnea, chest pain, abdominal pain, abnormal Q waves and ST-T changes were clearly different from the findings of myocarditis. However, large coronary lesions may occur in patients with an increased cardiothoracic ratio,[35] abnormal electrocardiogram (especially Q wave and ST-T changes),[36] echocardiographic evidence of reduced cardiac function, gallop rhythm or heart murmur,[37] especially when these findings occur after stage II.

Coronary Arterial Aneurysm

Coronary aneurysms were prospectively imaged with two dimensional echocardiography during stages II through III, primarily stage II. These findings concurred with the pathologic findings that large coronary arteritis occurred in stage I and large coronary aneurysms were observed in stage II.[29] Although coronary aneurysms were detected during stage III in three patients, we cannot be sure that these lesions occurred in stage III or were overlooked in stage II. In all 15 cases, two dimensional echocardiographic detection of the presence or absence of aneurysm of proximal portions of both the right and left coronary arteries correlated with angiographic data. The major limitation of two dimensional echocardiography in the diagnosis of coronary aneurysms was its inability to image the right coronary artery in 83 percent of our patients. Despite this limitation, large aneurysms of the right coronary artery (greater than 10 mm) were easily imaged.

Regression of coronary lesions and aneurysms: Angiographic studies[13,35] have confirmed that coronary aneurysms can either partially regress or completely disappear in stage V. Our serial two dimensional echocardiographic studies revealed that regression of coronary aneurysms may occur as early as stage III or IV. In these patients, angiographic evaluation was not performed in the active stages because it was considered dangerous. However, by stage IV or V when angiography was safe, two dimensional echocardiography was normal and angiography confirmed normal coronary anatomy. These data do not support previous angiographic reports[11,38] that demonstrated mild stenosis or arterial wall irregularities in stage IV or V. The difference may reflect our use of aortography rather than selective coronary angiography; however, this needs further study. Furthermore, serial echographic studies dem-

onstrated a thickening of the outer wall of the coronary aneurysm in one patient with angiographic evidence of regression. This information may indicate the pathologic process of aneurysm regression. In other words, aneurysm regression demonstrated angiographically does not imply complete recovery of the coronary artery but a reduction of its internal lumen due to some pathologic mechanism such as intimal thickening, granulation thrombi, scar formation or recanalization.[39]

Relation Between Carditis and Large Coronary Arterial Lesions

Panarteritis of large coronary arteries and inflammation of their vasa vasorum are suggested as important factors in the appearance of aneurysms.[39] However, this hypothesis has not been proved, and the relation between inflammation of myocardial microvessels and large coronary arteries has not been clarified. Our study showed that there was no distinct relation between coronary aneurysm formation and carditis, although it should be emphasized that carditis in this study is not a pathologic but a clinical diagnosis. No relation was found between the incidence and severity of carditis and the age of the patients. Conversely, severe coronary lesions were most often observed in infants. These patients had a longer period of elevation of the erythrocyte sedimentation rate and fever than the older patients. This age factor has previously been reported.[11,40] Therefore, we speculate that large coronary arteritis does not have direct continuity with inflammation of microvessels of the myocardium in stage I. The younger age group, primarily infants, may have either some anatomic weakness of the wall of a large coronary artery, as suggested by the report of Fujiwara et al.,[39] or a weak host defense mechanism such that severe inflammation is apt to occur in a large coronary artery, or both.

Acknowledgment

We are indebted to Hisayoshi Fujiwara, MD, of Kyoto University (Japan) for his advice concerning the cardiac pathology in mucocutaneous lymph node syndrome. We are also grateful for the technical assistance of Atsuko Takagi, Kimie Suzuki and Hiromi Uchida. We thank Thomas G. DiSessa, MD, and William F. Friedman, MD, of the University of California, Los Angeles School of Medicine for editorial assistance.

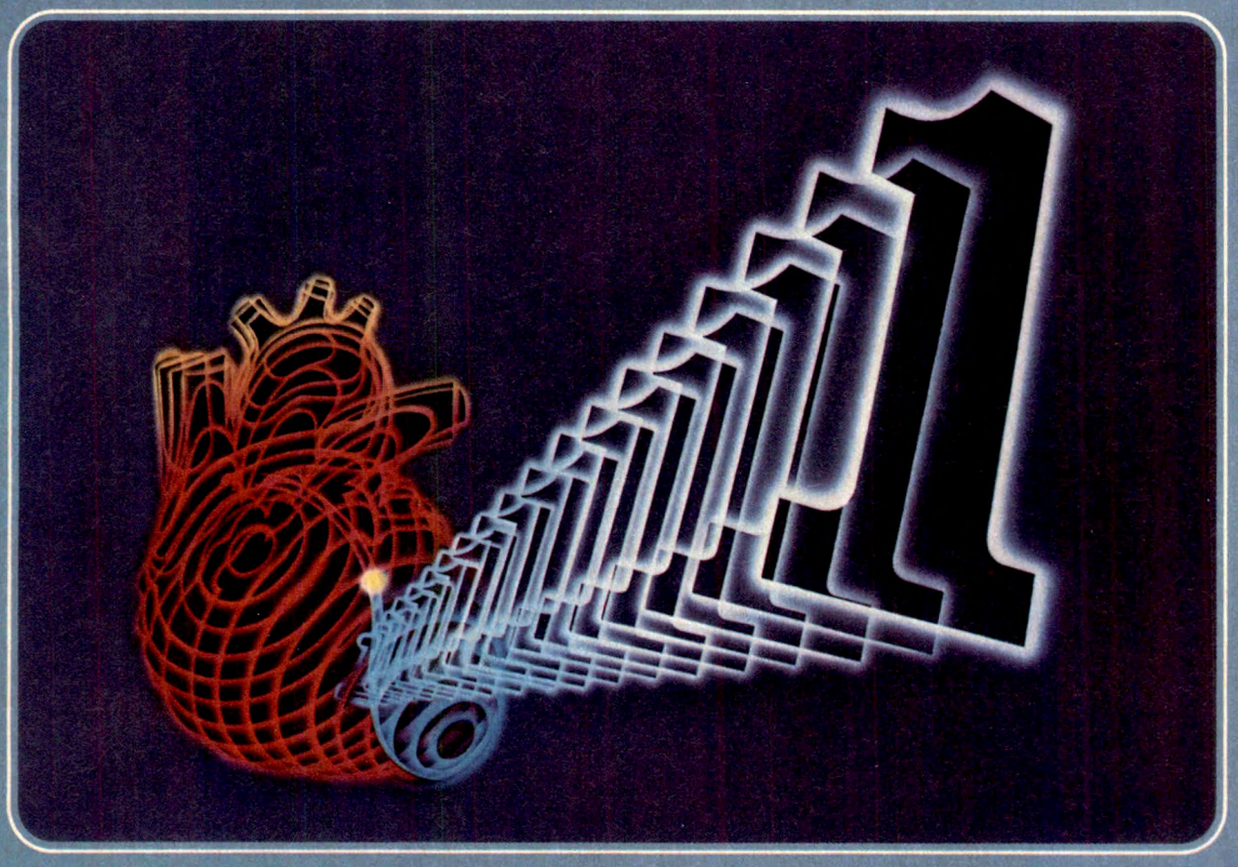
CORGARD®
nadolol tablets

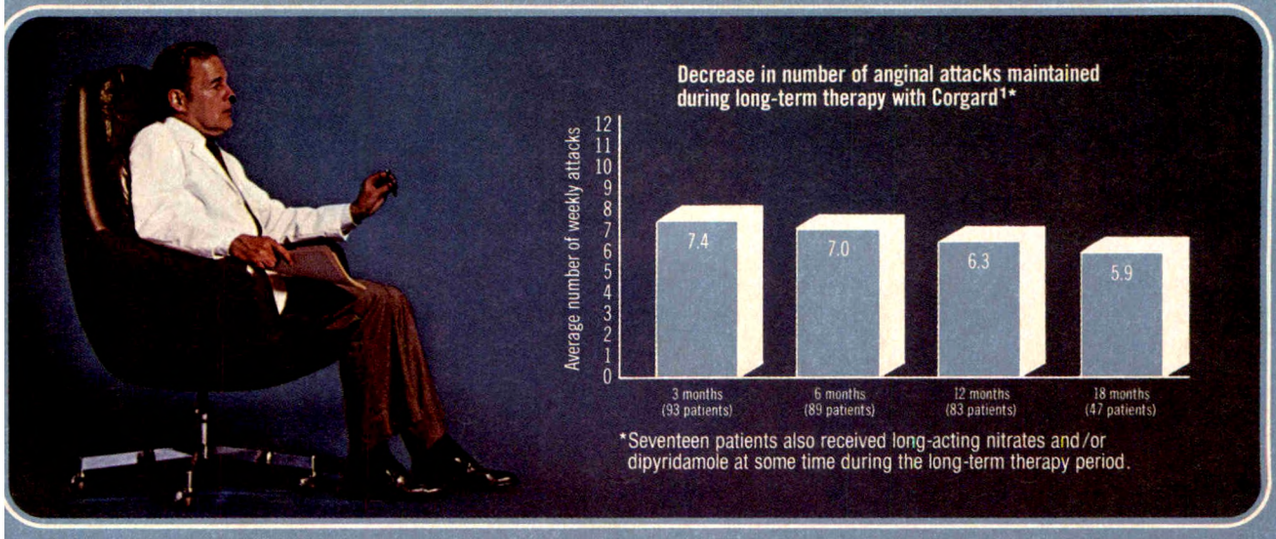


The first and only beta-blocker with once-a-day dosage

In the treatment of angina pectoris

SQUIBB

See last page of this advertisement for brief summary.



*Seventeen patients also received long-acting nitrates and/or dipyridamole at some time during the long-term therapy period.

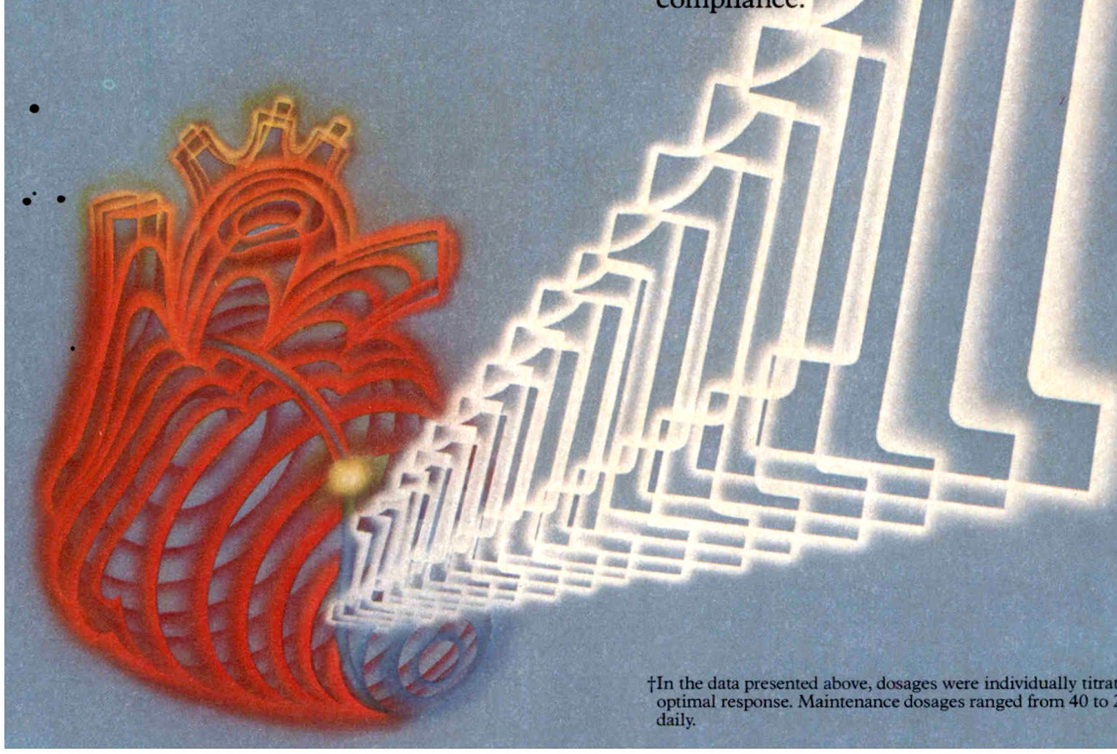
CORGARD® [nadolol tablets]:

Once-a-day, everyday, Corgard offers round-the-clock protection

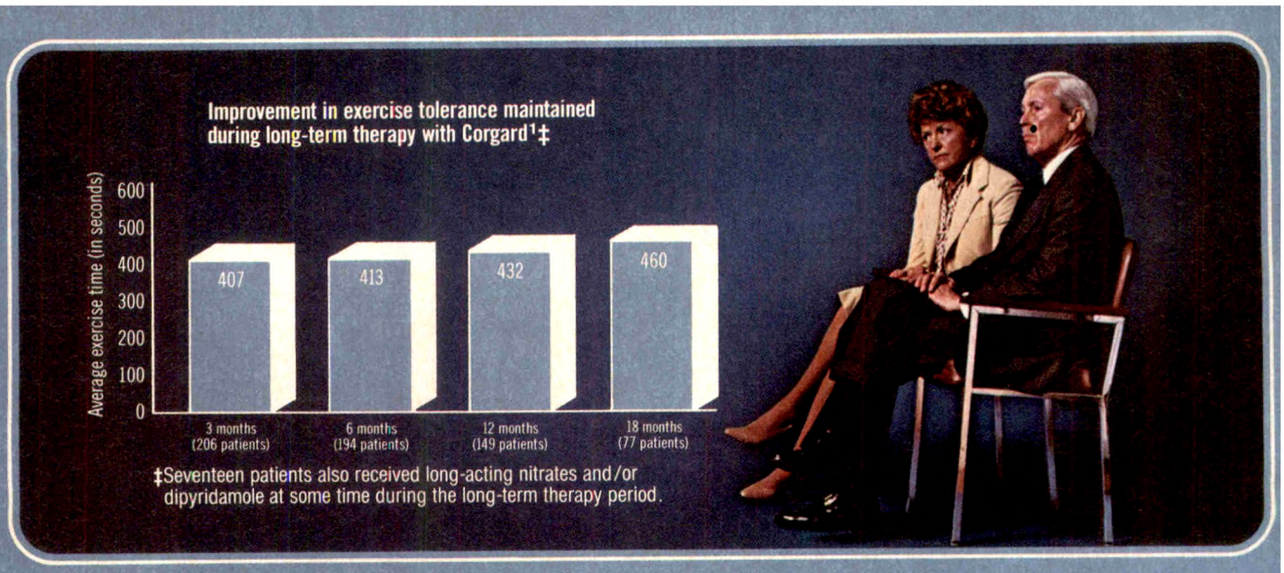
A single daily dose of Corgard offers prophylaxis in angina pectoris, helping to protect the patient all day and all night from painful attacks. And in extended clinical studies, the efficacy of Corgard — as demonstrated by a decreased rate of anginal attacks and an increase in exercise tolerance — was maintained.[1]

Once-a-day, everyday, Corgard decreases the frequency of anginal attacks

Corgard taken just once daily offers round-the-clock protection from angina pain. In one short-term study, Corgard, once a day, decreased the average number of anginal attacks per week in 115 patients with angina, from 13.6 pretherapy to 6.4 at the end of 14 weeks of therapy, a mean decrease of 59%.[1†] In 19% of the 115 patients, anginal attacks were completely eliminated. And the long half-life (20 to 24 hours) makes Corgard the once-a-day beta-blocker, promoting patient compliance.



†In the data presented above, dosages were individually titrated to achieve optimal response. Maintenance dosages ranged from 40 to 240 mg Corgard daily.



Effective control of angina pectoris

Once-a-day, everyday, Corgard increases exercise tolerance

Corgard allows the angina patient to do more. In 147 patients in the same short-term study as the one at left, Corgard, once a day, increased ergometry time by 25%, improving exercise tolerance from an average of 365 seconds pretherapy to 427 seconds at the end of 14 weeks of therapy.[1] In 21% of the 147 patients, the end point of exercise was fatigue rather than angina pain. And the single daily dose of Corgard can be taken at the patient's convenience, without regard to meals.

Once-a-day, everyday, Corgard decreases nitroglycerin usage[1]

Corgard blocks catecholamine influence on myocardial activity, decreases myocardial oxygen demand, and does not have a direct myocardial depressant effect.

Prescribe

CORGARD®

CORGARD®
nadolol tablets
40 mg, 80 mg, 120 mg, 160 mg scored tablets

CORGARD® TABLETS
Nadolol Tablets

DESCRIPTION: Corgard (nadolol) is a synthetic nonselective beta-adrenergic receptor blocking agent.

CONTRAINDICATIONS: Bronchial asthma, sinus bradycardia and greater than first degree conduction block, cardiogenic shock, and overt cardiac failure (see WARNINGS).

WARNINGS: Cardiac Failure—Sympathetic stimulation may be a vital component supporting circulatory function in congestive heart failure, and its inhibition by beta-blockade may precipitate more severe failure. Although beta-blockers should be avoided in overt congestive heart failure, if necessary, they can be used with caution in patients with a history of failure who are well-compensated, usually with digitalis and diuretics. Beta-adrenergic blocking agents do not abolish the inotropic action of digitalis on heart muscle. IN PATIENTS WITHOUT A HISTORY OF HEART FAILURE, continued use of beta-blockers can, in some cases, lead to cardiac failure; therefore, at first sign or symptom of heart failure, digitalize and/or give diuretics, and closely observe response, or discontinue nadolol (gradually if possible).

Exacerbation of Ischemic Heart Disease Following Abrupt Withdrawal — Hypersensitivity to catecholamines has been observed in patients withdrawn from beta-blocker therapy; exacerbation of angina and, in some cases, myocardial infarction have occurred after *abrupt* discontinuation of such therapy. When discontinuing chronic use of nadolol, particularly in patients with ischemic heart disease, gradually reduce dosage over a 1- to 2-week period and carefully monitor the patient. Reinstitute nadolol promptly (at least temporarily) and take other measures appropriate for management of unstable angina if angina markedly worsens or acute coronary insufficiency develops. Warn patients not to interrupt or discontinue therapy without physician's advice. Because coronary artery disease is common and may be unrecognized, it may be prudent not to discontinue nadolol therapy abruptly even in patients treated only for hypertension.

Nonallergic Bronchospasm (e.g., chronic bronchitis, emphysema) — PATIENTS WITH BRONCHOSPASTIC DISEASES SHOULD IN GENERAL NOT RECEIVE BETA-BLOCKERS. Administer nadolol with caution since it may block bronchodilation produced by endogenous or exogenous catecholamine stimulation of $beta_2$ receptors.

Major Surgery — Because beta-blockade impairs the ability of the heart to respond to reflex stimuli and may increase risks of general anesthesia and surgical procedures, resulting in protracted hypotension or low cardiac output, it has generally been suggested that such therapy should be withdrawn several days prior to surgery. Recognition of the increased sensitivity to catecholamines of patients recently withdrawn from beta-blocker therapy, however, has made this recommendation controversial. If possible, withdraw beta-blockers well before surgery takes place. In emergency surgery, inform the anesthesiologist that the patient is on beta-blocker therapy. Use of beta-receptor agonists such as isoproterenol, dopamine, dobutamine, or levarterenol can reverse the effects of nadolol. Difficulty in restarting and maintaining the heart beat has also been reported with beta-adrenergic receptor blocking agents.

Diabetes and Hypoglycemia — Beta-adrenergic blockade may prevent the appearance of premonitory signs and symptoms (e.g., tachycardia and blood pressure changes) of acute hypoglycemia. This is especially important with labile diabetics. Beta-blockade also reduces release of insulin in response to hyperglycemia; therefore, it may be necessary to adjust dose of antidiabetic drugs.

Thyrotoxicosis — Beta-adrenergic blockade may mask certain clinical signs (e.g., tachycardia) of hyperthyroidism. To avoid abrupt withdrawal of beta-adrenergic blockade which might precipitate a thyroid storm, carefully manage patients suspected of developing thyrotoxicosis.

PRECAUTIONS: Impaired Hepatic or Renal Function — Use nadolol with caution in presence of either of these conditions (see DOSAGE AND ADMINISTRATION section of package insert).

Information for Patients — Warn patients, especially those with evidence of coronary artery insufficiency, against interruption or discontinuation of nadolol without physician's advice. Although cardiac failure rarely occurs in properly selected patients, advise patients being treated with beta-adrenergic blocking agents to consult physician at first sign or symptom of impending failure.

Drug Interactions — Catecholamine-depleting drugs (e.g., reserpine) may have an additive effect when given with beta-blocking agents. When treating patients with nadolol plus a catecholamine-depleting agent, carefully observe for evidence of hypotension and/or excessive bradycardia which may produce vertigo, syncope, or postural hypotension.

Carcinogenesis, Mutagenesis, Impairment of Fertility — In 1 to 2 years' oral toxicologic studies in mice, rats, and dogs, nadolol did not produce significant toxic effects. In 2-year oral carcinogenic studies in rats and mice, nadolol did not produce neoplastic, preneoplastic, or nonneoplastic pathologic lesions.

Pregnancy — In animal reproduction studies with nadolol, evidence of embryo- and fetotoxicity was found in rabbits (but not in rats or hamsters) at doses 5 to 10 times greater (on a mg/kg basis) than maximum indicated human dose; no teratogenic potential was seen in any of these species. There are no well-controlled studies in pregnant women; therefore, use nadolol in pregnant women only if potential benefit justifies potential risk to the fetus.

Nursing Mothers — It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, exercise caution when nadolol is administered to a nursing woman. Animal studies showed that nadolol is found in the milk of lactating rats.

Pediatric Use — Safety and effectiveness in children have not been established.

ADVERSE REACTIONS: Most adverse effects have been mild and transient and have rarely required nadolol withdrawal.

Cardiovascular — Bradycardia with heart rates of less than 60 beats per minute occurs commonly, and heart rates below 40 beats per minute and/or symptomatic bradycardia were seen in about 2 of 100 patients. Symptoms of peripheral vascular insufficiency, usually of the Raynaud type, have occurred in approximately 2 of 100 patients. Cardiac failure, hypotension, and rhythm/conduction disturbances have each occurred in about 1 of 100 patients. Single instances of first degree and third degree heart block have been reported; intensification of AV block is a known effect of beta-blockers (see also CONTRAINDICATIONS, WARNINGS, and PRECAUTIONS). **Central Nervous System** — Dizziness or fatigue reported in approximately 2 of 100 patients; paresthesias, sedation, and change in behavior reported in approximately 6 of 1000 patients. **Respiratory** — Bronchospasm reported in approximately 1 of 1000 patients (see CONTRAINDICATIONS and WARNINGS). **Gastrointestinal** — Nausea, diarrhea, abdominal discomfort, constipation, vomiting, indigestion, anorexia, bloating, and flatulence each reported in 1 to 5 of 1000 patients. **Miscellaneous** — Each of the following reported in 1 to 5 of 1000 patients: rash; pruritus; headache; dry mouth, eyes, or skin; impotence or decreased libido; facial swelling; weight gain; slurred speech; cough; nasal stuffiness; sweating; tinnitus; blurred vision. Although relationship to drug usage is not clear, sleep disturbances have been reported. The oculomucocutaneous syndrome associated with practolol has not been reported with nadolol.

Potential Adverse Effects: Although other adverse effects reported with other beta-adrenergic blocking agents have not been reported with nadolol, they should be considered potential adverse effects of nadolol. **Central Nervous System** — reversible mental depression progressing to catatonia; visual disturbances; hallucinations; an acute reversible syndrome characterized by disorientation for time and place; short-term memory loss, emotional lability with slightly clouded sensorium; decreased performance on neuropsychometrics. **Gastrointestinal** — mesenteric arterial thrombosis; ischemic colitis. **Hematologic** — agranulocytosis; thrombocytopenic or nonthrombocytopenic purpura. **Allergic** — fever combined with aching and sore throat; laryngospasm; respiratory distress. **Miscellaneous** — reversible alopecia; Peyronie's disease; erythematous rash.

OVERDOSAGE: Nadolol can be removed from the general circulation by hemodialysis. In addition to gastric lavage, employ the following measures as appropriate. In determining duration of corrective therapy, take note of long duration of effect of nadolol.

Excessive Bradycardia — Administer atropine (0.25 to 1.0 mg). If there is no response to vagal blockade, administer isoproterenol cautiously.

Cardiac Failure — Administer a digitalis glycoside and diuretic. It has been reported that glucagon may also be useful in this situation.

Hypotension — Administer vasopressors, e.g., epinephrine or levarterenol. (There is evidence that epinephrine may be the drug of choice.)

Bronchospasm — Administer a $beta_2$-stimulating agent and/or a theophylline derivative.

DOSAGE: For all patients, DOSAGE MUST BE INDIVIDUALIZED.

For **angina pectoris,** usual initial dose is 40 mg q.d.; gradually increase in 40 to 80 mg increments at 3 to 7 day intervals until optimum clinical response or pronounced slowing of the heart rate; usual maintenance dose is 80 to 240 mg q.d. (most patients respond to 1 mg or less daily). If treatment is to be discontinued, reduce dosage gradually over a period of 1 to 2 weeks (see WARNINGS).

For **hypertension,** usual initial dose is 40 mg q.d.; gradually increase in 40 to 80 mg increments until optimum blood pressure reduction is achieved; usual maintenance dose is 80 to 320 mg q.d. (rarely, doses up to 640 mg may be needed).

Patients with renal failure require adjustment in dosing interval — see package insert for dosage in these patients.

For full prescribing information, consult package insert.

HOW SUPPLIED: In scored tablets containing 40, 80, 120, or 160 mg nadolol per tablet in bottles of 100 and 1000 tablets and in Unimatic® single-dose packs of 100 tablets.

INTRODUCING OUR NEW NAME

Why change a respected name like HANCOCK Laboratories Inc.?

Because, good as it is, HANCOCK tends to bring to mind porcine heart valves. Which *is* where we started.

Today, however, we're much broader than that. And, it is our objective to continue to expand our product line for an increased presence in and commitment to cardiovascular health care.

Under VASCOR, three new product lines:

- HANCOCK* porcine heart valves
- CARDAK* thermodilution and other right heart catheters
- VICARE* cardiovascular therapeutic products

VASCOR INC.
Anaheim, California 92807
Committed to your needs.

VASCOR

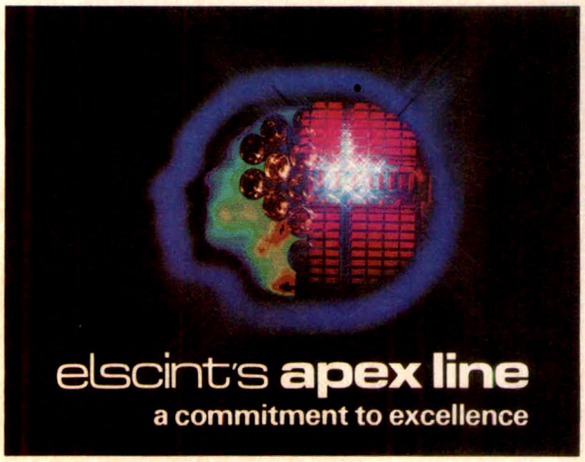
elscint's tri-pex process and image quality

Tri-pex: another unique feature of the Apex Line

ntil Apex, ideal gamma camera performance as never achieved. Good resolution meant poor niformity—and vice versa. Even today, most anufacturers do the best they can with resolution, nd cover up nonuniformity by a simple computer ck: artificial image modulation. Only Elscint *solves* e problem—with TRI-PEX, a unique triple rrection that gives Apex the best combination of solution, uniformity and linearity in Nuclear edicine.



'scint Inc.
'8-160 Johnson Avenue,
ackensack, N.J. 07602, U.S.A.
all Toll Free: 800-631-1694

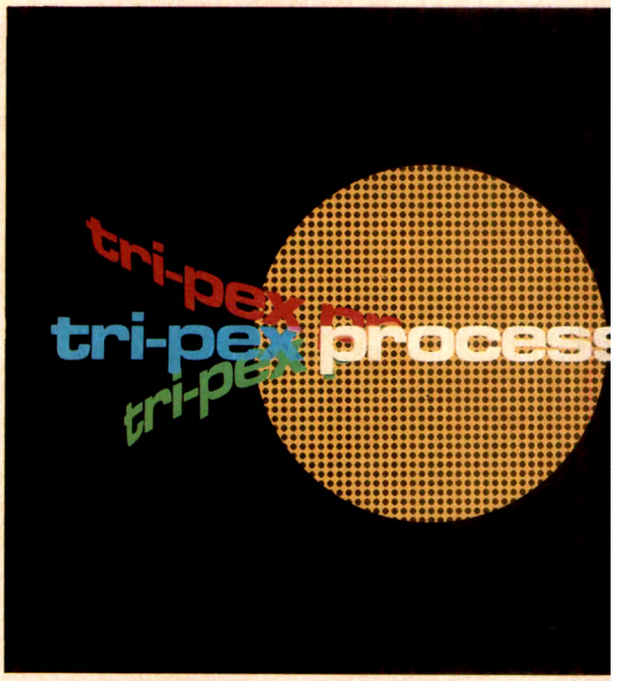
lscint's Unique TRI-PEX Process:

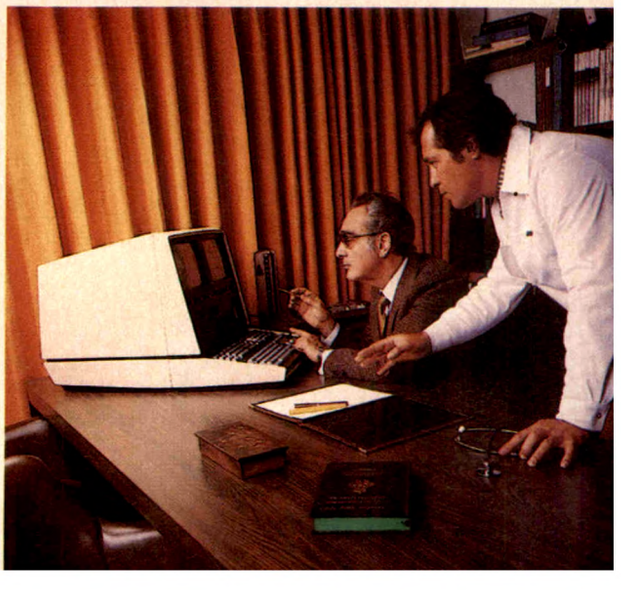
ne Energy Correction
or each individual Apex camera, the energy over e entire field of view is measured. When an nergy window is selected, the system utomatically generates a set of "local windows." uring acquisition each event is selected or jected according to the local window value.

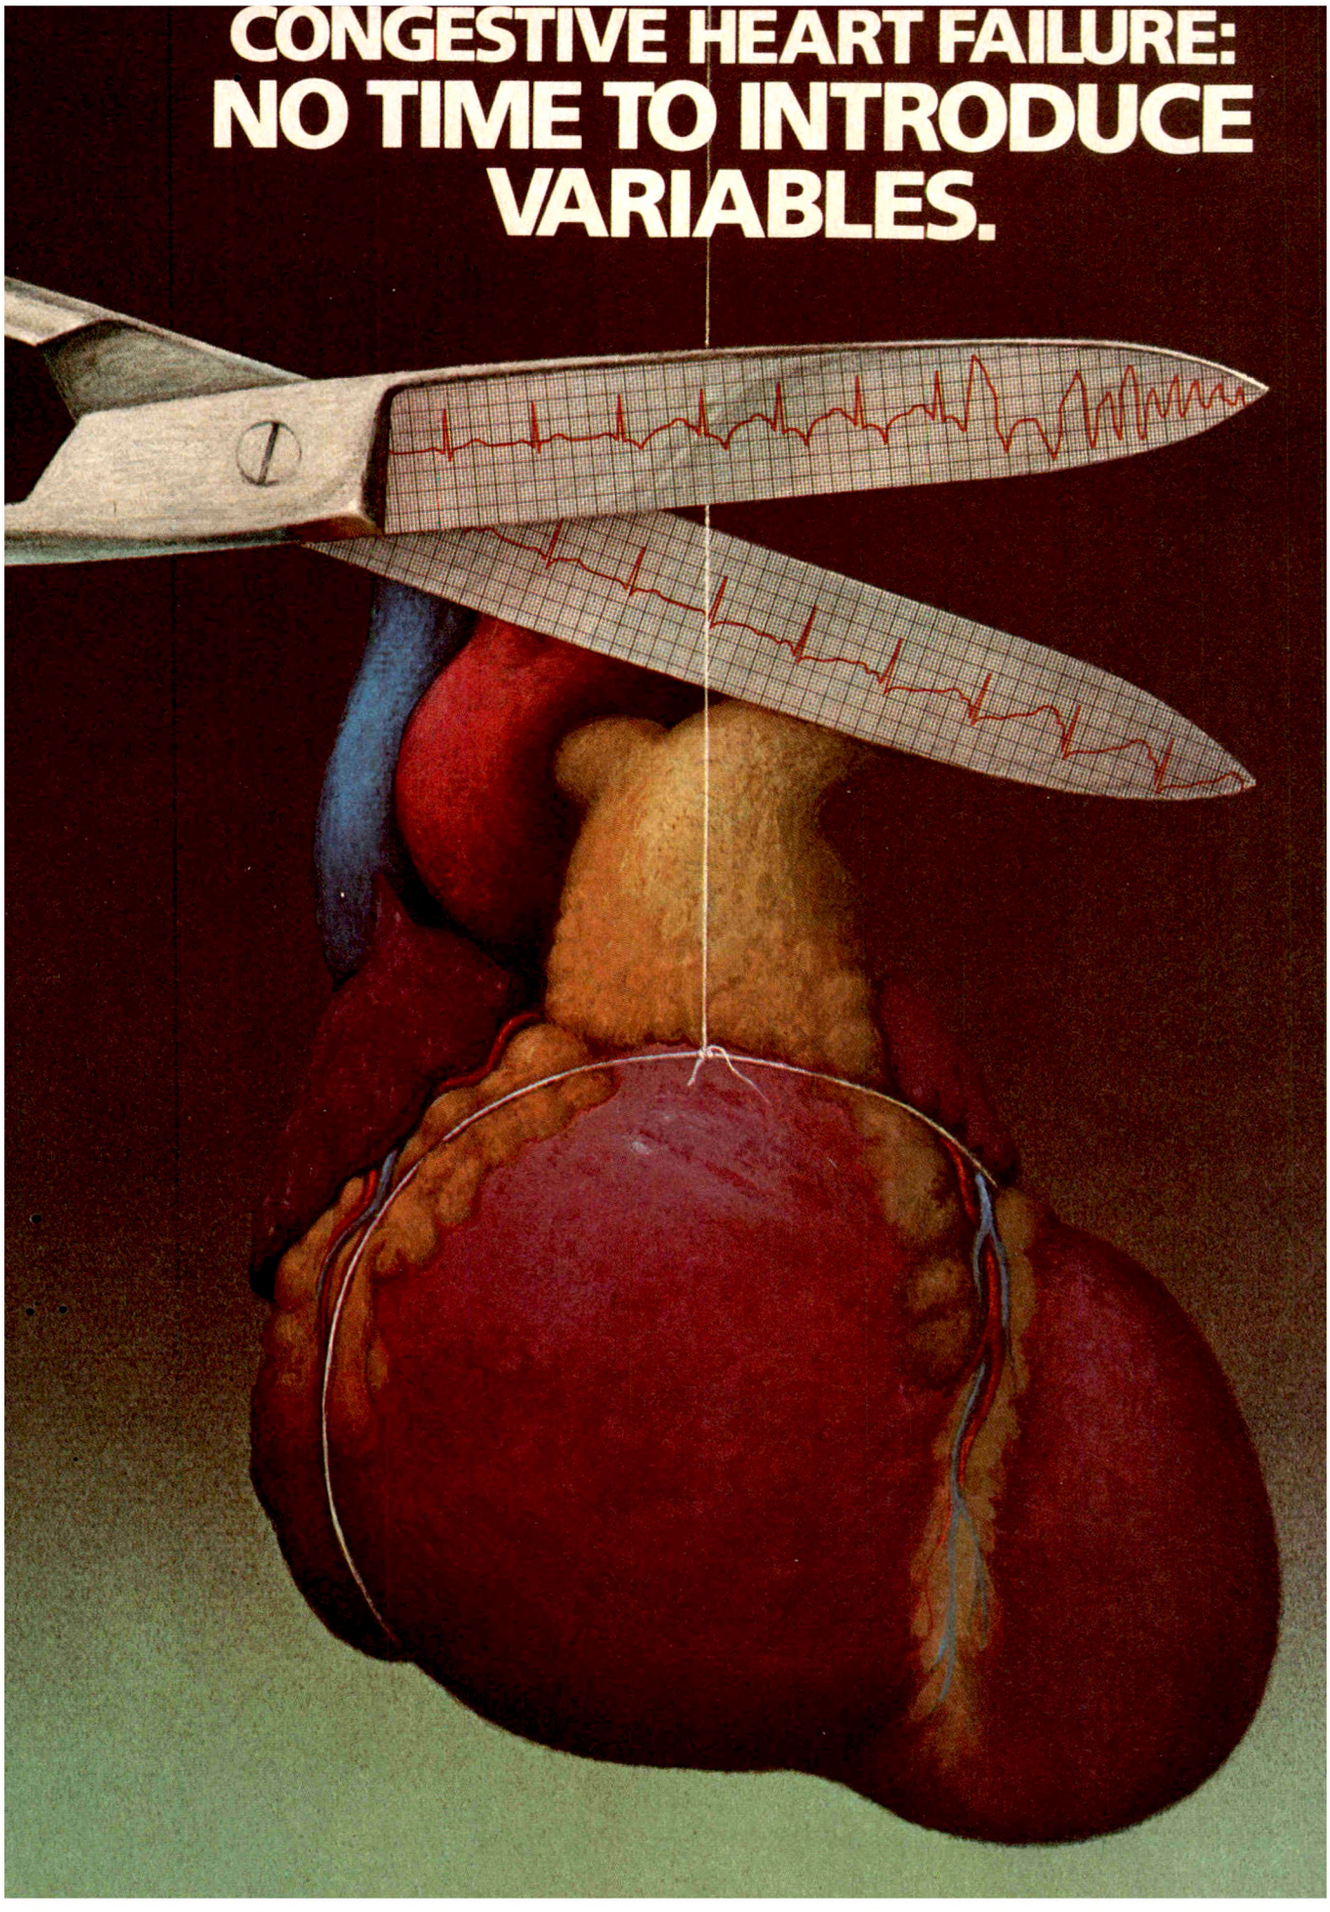
ne Displacement Correction
patial distortions are mapped over the entire field view. During acquisition, a special bit-slice ocessor "returns" each displaced event to its iginal position, in real-time, as it appears.

ne Sensitivity Correction
ny residual nonuniformity caused by variations in llimator sensitivity or by other intrinsic factors is rrected by quantifying sensitivity over the entire ld of view. Nonuniformity is now eliminated by tomatically normalizing the image count with e aid of a precise 256^2 reference matrix.

scint's TRI-PEX process has a triple advantage, too:
No loss of data through "count skipping."
No loss of detail through artificial image anipulation.
Corrections automatically performed on-line th no additional post-acquisition processing time quired.
e exceptional results achieved by Elscint's I-PEX process are safeguarded by an clusive electro-optical stabilization system hich maintains constant circuit balance without







CONGESTIVE HEART FAILURE:
NO TIME TO INTRODUCE
VARIABLES.

If you wouldn't think of changing your brand of digitalis, shouldn't you think twice before switching from LASIX® furosemide to a substitute?

BRAND OF

Both digitalis and diuretics are almost always used in congestive heart failure. But both can cause serious cardiac arrhythmias.[1] Digitalis, because digitalization is one of the most precarious titrations in all of medicine. And diuretics, because diuretic-induced hypokalemia increases the vulnerability to digitalis toxicity.[2] See warnings and precautions in the brief summary of product information on the next page.

In serious congestive heart failure, the diuretic most frequently administered with digitalis is LASIX® brand of furosemide. However, the bioavailability of furosemide may be significantly altered by a change in tablet disintegrants and/or excipients.[3,4,5] And variations in the bioavailability of unlawfully-marketed furosemide tablets have produced unpredictable and serious clinical effects.[6]

Therefore, once the patient is stabilized on digitalis and LASIX®, changes in his cardiac regimen should be minimized.

LASIX®—the diuretic with the best record of success in all degrees of congestive heart failure.

LASIX® is the original brand of furosemide. It is LASIX® that established the standard for furosemide performance. It is LASIX® that is the subject of almost 6,000 published papers. It is LASIX® that has been used successfully in millions of digitalized patients over the past 14 years. And it is LASIX® that has a remarkable quality-control record—almost 8 billion tablets manufactured without a single product recall.

LASIX® tablets are available in a dosage strength to meet almost every patient need—20, 40 and 80 mg.

Before prescribing, please consult complete product information, a summary of which appears on the following page.

LASIX®
FUROSEMIDE

ONE LESS VARIABLE IN THE DIGITALIZED PATIENT

Lasix® (furosemide)

A brief summary of the Prescribing Information for Lasix (furosemide). Tablets 20, 40 and 80 mg.

WARNING: Lasix (furosemide) is a potent diuretic which, if given in excessive amounts, can lead to a profound diuresis with water and electrolyte depletion. Therefore, careful medical supervision is required and dose and dose schedule have to be adjusted to the individual patient's needs.

INDICATIONS: Edema associated with congestive heart failure, cirrhosis of the liver, and renal disease, including the nephrotic syndrome. Hypertension when used alone or in combination with other antihypertensive drugs; patients not adequately controlled with thiazides also probably will not be adequately controlled with furosemide alone.

CONTRAINDICATIONS: Because animal reproductive studies have shown that furosemide may cause fetal abnormalities, the drug is contraindicated in women of childbearing potential. Anuria. History of hypersensitivity to the compound.

WARNINGS: Excessive diuresis may result in dehydration and reduction in blood volume, with circulatory collapse and with the possibility of vascular thrombosis and embolism, particularly in elderly patients. Excessive loss of potassium in patients receiving digitalis glycosides may precipitate digitalis toxicity. Exercise care in patients receiving potassium-depleting steroids. Perform frequent serum electrolyte, CO_2, and BUN determinations during first few months of therapy and periodically thereafter, and correct abnormalities or temporarily withdraw the drug. Initial therapy of patients with hepatic cirrhosis and ascites is best carried out in the hospital. Closely observe cirrhotic patients for sudden fluid and electrolyte imbalances that may precipitate hepatic coma. Supplemental potassium chloride and, if required, an aldosterone antagonist are helpful in preventing hypokalemia and metabolic alkalosis. Discontinue furosemide if increasing azotemia and oliguria occur during treatment of severe, progressive renal disease. Observe patients regularly for possible blood dyscrasias, liver damage, or other idiosyncratic reactions. Patients with known sulfonamide sensitivity may show allergic reactions. Furosemide may potentiate the therapeutic effect of other antihypertensive agents. Potentiation occurs with ganglionic or peripheral adrenergic blocking drugs. Exacerbation or activation of systemic lupus erythematosus may occur. Furosemide appears in breast milk. If use of the drug is essential, the patient should stop nursing. Cases of tinnitus and reversible hearing impairment have been reported.

There have also been some reports of cases in which irreversible hearing impairment occurred. Usually ototoxicity has been reported when furosemide was injected rapidly in patients with severe impairment of renal function at doses exceeding several times the usual recommended dose and in whom other drugs known to be ototoxic were given. If the physician elects to use high-dose parenteral therapy in patients with severely impaired renal function, controlled intravenous infusion is advisable. (For adults, an infusion rate not exceeding 4 mg furosemide per minute has been used.)

PRECAUTIONS: As with any effective diuretic, electrolyte depletion may occur, especially in patients receiving higher doses and a restricted salt intake. Patients receiving furosemide should be observed for clinical signs of fluid or electrolyte imbalance, namely, hyponatremia, hypochloremic alkalosis, and hypokalemia. Serum and urine electrolyte determinations are particularly important when the patient is vomiting excessively or receiving parenteral fluids. Medication such as digitalis may also influence serum electrolytes. Hypokalemia may develop with furosemide as with any other potent diuretic, especially with brisk diuresis, when cirrhosis is present, or during concomitant use of corticosteroids or ACTH. Interference with adequate oral electrolyte intake will also contribute to hypokalemia. Digitalis may exaggerate metabolic effects of hypokalemia, especially with reference to myocardial activity. Asymptomatic hyperuricemia can occur and gout may rarely be precipitated. Increases in blood glucose and alterations in glucose tolerance tests with abnormalities of the fasting and two-hour postprandial sugar have been observed, and rare cases of precipitation of diabetes mellitus have been reported. Furosemide may lower serum calcium levels, and rare cases of tetany have been reported. Periodic serum calcium levels should be obtained. Reversible elevations of BUN may be seen. These have been observed in association with dehydration, which should be avoided, particularly in patients with renal insufficiency. Patients receiving high doses of salicylates in conjunction with furosemide may experience salicylate toxicity at lower doses because of competitive renal excretory sites. Furosemide has a tendency to antagonize the effects of tubocurarine and may potentiate the action of succinylcholine. Lithium generally should not be given with diuretics because they reduce its renal clearance and add a high risk of lithium toxicity. Diuretics such as furosemide may enhance the nephrotoxicity of cephaloridine. Therefore, furosemide and cephaloridine should not be administered simultaneously. Furosemide may decrease arterial responsiveness to norepinephrine. This diminution is not sufficient to preclude effectiveness of the pressor agent for therapeutic use.

It has been reported in the literature that coadministration of indomethacin may reduce the natriuretic and antihypertensive effects of Lasix (furosemide) in some patients. This effect has been attributed to inhibition of prostaglandin synthesis by indomethacin. Indomethacin may also affect plasma renin levels and aldosterone excretion: this should be borne in mind when a renin profile is evaluated in hypertensive patients. Patients receiving both indomethacin and Lasix (furosemide) should be observed closely to determine if the desired diuretic and/or antihypertensive effect of Lasix (furosemide) is achieved.

ADVERSE REACTIONS: Anorexia, oral and gastric irritation, nausea, vomiting, cramping, diarrhea, constipation, jaundice (intrahepatic jaundice), pancreatitis, dizziness, vertigo, paresthesias, headache, xanthopsia, blurred vision, tinnitus and hearing loss, anemia, leukopenia, agranulocytosis (rare), thrombocytopenia, aplastic anemia (rare), purpura, photosensitivity, rash, urticaria, necrotizing angiitis (vasculitis, cutaneous vasculitis), exfoliative dermatitis, erythema multiforme, pruritus. Orthostatic hypotension may occur and may be exaggerated by alcohol, barbiturates, or narcotics. Other adverse reactions include hyperglycemia, glycosuria, hyperuricemia, muscle spasm, weakness, restlessness, urinary bladder spasm, thrombophlebitis.

Announcing the comprehensive study of...the most fascinating syndrome in Cardiology...

THE PRE-EXCITATION SYNDROME: FACTS AND THEORIES

Libi Sherf, MD, FACC

Assoc. Professor of Cardiology, Heart Institute, Chaim Sheba Medical Center, Tel Hashomer, University of Tel Aviv—Sackler School of Medicine, and Visiting Assoc. Professor, Dept. of Medicine, University of Alabama.

Henry N. Neufeld, MD, FACC

Professor of Medicine and Chaim Sheba Professor of Cardiology, Chief, Heart Institute, Chaim Sheba Medical Center, Tel Hashomer, University of Tel Aviv—Sackler School of Medicine.

Every cardiologist, internist, pediatrician, surgeon—indeed, *every physician*—should have a good basic knowledge of the Pre-excitation Syndrome. Here are just a few reasons why this is so essential:

- ☐ ⅓ of all pre-excitation cases are misdiagnosed.
- ☐ 5% to 10% of all tachycardias in adults are produced by pre-excitation.
- ☐ In ½ of all infants under 10 months of age with life-threatening tachycardias, the tachycardias are actually secondary to pre-excitation.
- ☐ ⅓ to ½ of all children with pre-excitation have an additional heart disease.

Starting with Wolff, Parkinson and White's classic paper, this book gives a comprehensive summary of all important facts of pre-excitation, plus the authors' personal experiences of follow-up studies of patients through many decades. It also brings a broad view of the literature and discusses the different structural and physiological aspects which form the pathomechanism of pre-excitation.

"What is offered richly in this book is a methodical and comprehensive analysis of virtually all currently available knowledge on the subject. This is done with an admirable even-handedness, dealing objectively with all viewpoints but at the same time evaluating relative strengths and weaknesses of each observation and hypothesis. There is brought a wisdom here which only time and experience can provide. The encyclopedic references alone would make the book invaluable to anyone seriously interested in the Wolff-Parkinson-White syndrome. But when knowledgeable discussion and personal observations are added, it is genuinely a monumental contribution to clinical cardiology and cardiac electrophysiology."

Thomas N. James, MD
The Mary Gertrude Waters Professor of Cardiology and Chairman of the Department of Medicine, The University of Alabama in Birmingham, and Physician-in-Chief, University of Alabama Hospitals.

YORKE MEDICAL BOOKS, 666 Fifth Ave., N.Y., N.Y. 10103

Please send me a copy of THE PRE-EXCITATION SYNDROME at $33.00. I may use the book for 30 days and if not completely satisfied, return it for full refund or credit.

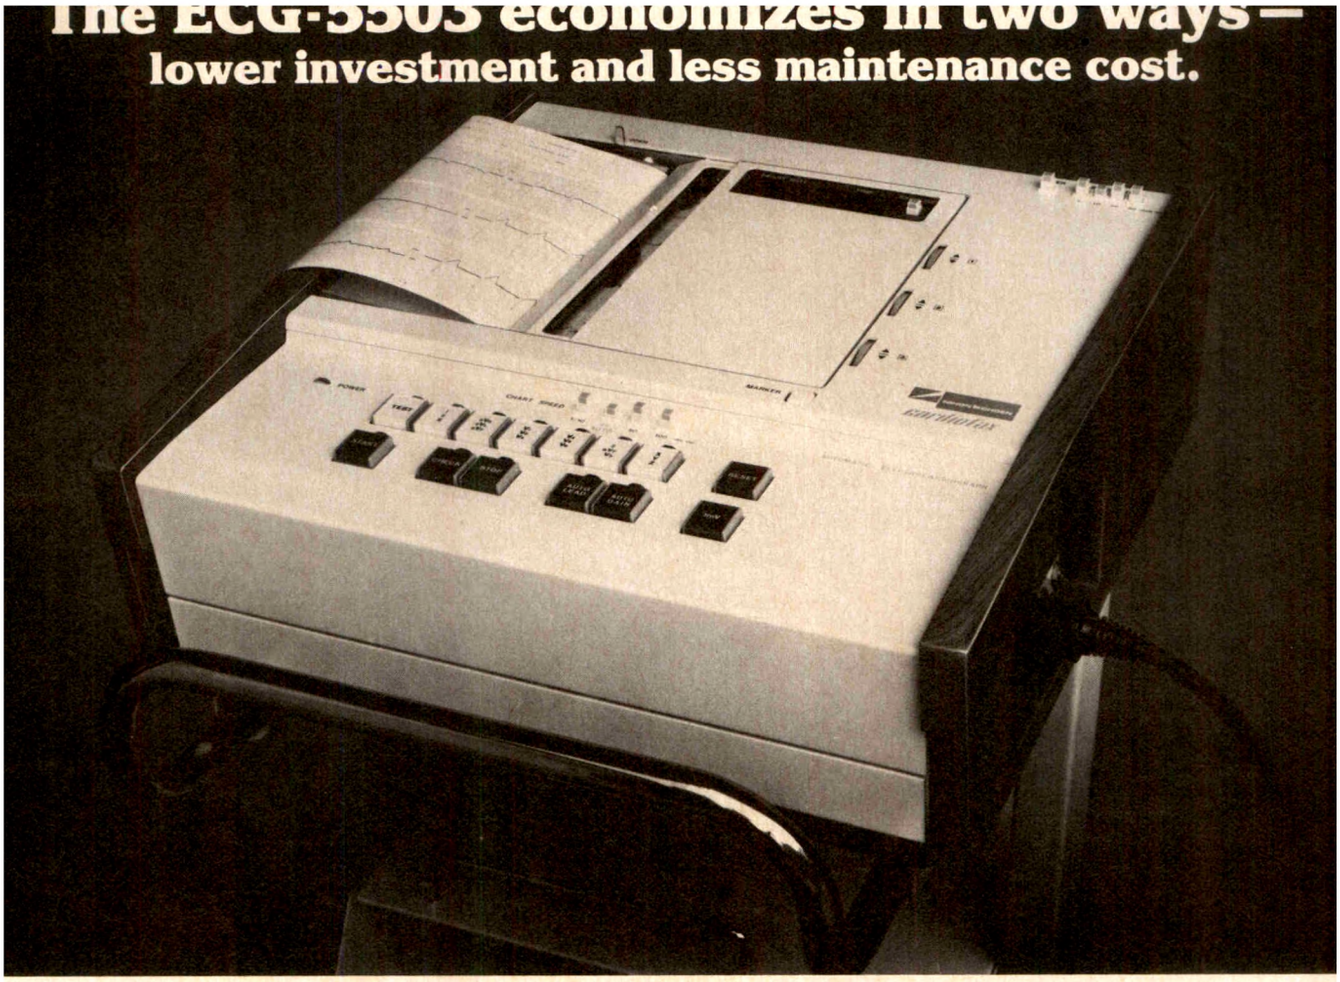
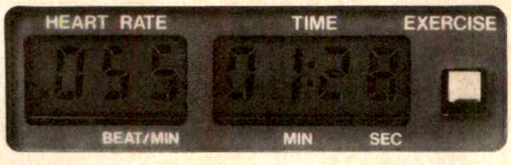
The ECG-5503 economizes in two ways—lower investment and less maintenance cost.



Nihon Kohden's time-tested and clinically-proven research and experience now make available an advanced, rugged wide 3½-channel electrocardiograph. Designed with better diagnostic accuracy and less maintenance cost in mind, the ECG-5503 offers additional advantages including:

Digital Exercise Timer
Push the "Exercise" button at the start of the stress test and the exercise time will be displayed.

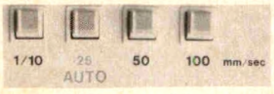
Automatic Exercise Recording Protocol
Recording interval is adjustble, by a switch located behind the pen cover, to permit automatic programmed recording.



Digital Heart Rate Meter
The ECG-5503 is the only 3-channel electrocardiograph which features a heart rate meter. It indicates the heart rate during ECG measurement.

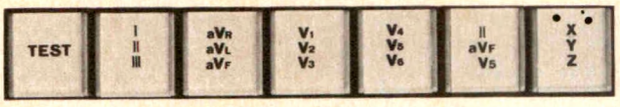
Continuous Rhythm Analysis
Automatic protocol allows a rhythm strip speed of 5mm/sec for arrhythmia trending during exercise.

Six Chart Speeds



In addition to standard chart speeds of 25, 50 and 100mm/sec., 1/10 speeds are possible to facilitate stress ECG monitoring and irregular rhythm recording.

Quartz Controlled Chart Speed and Timing Mark
Clear Crystal-Cut Traces
AC Filter and Defibrillation Protection



5th Lead Group plus Frank's X, Y, Z System
An extra lead group of II, aVF and V5 is provided to enhance rhythm observation.

Nihon Kohden (America) is introducing this new model ECG-5503 automatic electrocardiograph with all these features at only $5995.

Let our sales & service network show you why Nihon Kohden, with over 30 years experience, is the world leader in quality ECG's.

REPORT OF THE JOINT NATIONAL
COMMITTEE ON DETECTION, EVALUATION
AND TREATMENT OF
HIGH BLOOD PRESSURE

ANOTHER FIRST FOR INDERAL®
(PROPRANOLOL HCl)

NOW RECOMMENDED FOR INITIAL THERAPY IN SELECTED HYPERTENSIVE PATIENTS

"In selected younger patients with a rapid heart rate and/or high pulse pressure, beta-adrenergic blocking agents may be appropriate for Step 1 drug therapy."

—Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure, 1980.

INDERAL®

(PROPRANOLOL HCl)

BID FOR HYPERTENSION

Please see following page for Brief Summary of Prescribing Information on Contraindications, Precautions, Adverse Reactions, and Warnings, including avoidance of abrupt withdrawal.

INDERAL®

(PROPRANOLOL HCl) B.I.D. FOR HYPERTENSION

BRIEF SUMMARY
(FOR FULL PRESCRIBING INFORMATION, SEE PACKAGE CIRCULAR.)
Inderal® BRAND OF
propranolol hydrochloride
A beta-adrenergic blocking agent

BEFORE USING INDERAL (PROPRANOLOL HYDROCHLORIDE), THE PHYSICIAN SHOULD BE THOROUGHLY FAMILIAR WITH THE BASIC CONCEPT OF ADRENERGIC RECEPTORS (ALPHA AND BETA), AND THE PHARMACOLOGY OF THIS DRUG.

ACTIONS

The mechanism of the antihypertensive effects of INDERAL has not been established. Among the factors that may be involved in the antihypertensive action are (1) decreased cardiac output, (2) inhibition of renin release by the kidneys, and (3) diminution of tonic sympathetic nerve outflow from vasomotor centers in the brain.

Propranolol hydrochloride decreases heart rate, cardiac output, and blood pressure. Although total peripheral vascular resistance may increase initially, it readjusts to the pretreatment level, or lower, with chronic usage. Earlier studies indicate that plasma volume remains unchanged or may decrease. However, there are certain more recent studies suggesting that in the absence of sodium restriction, plasma volume may increase.

INDICATIONS

Hypertension
INDERAL is indicated in the management of hypertension. It is usually used in combination with other drugs, particularly a thiazide diuretic. INDERAL is not indicated for treatment of hypertensive emergencies.

CONTRAINDICATIONS

INDERAL is contraindicated in: 1) bronchial asthma; 2) allergic rhinitis during the pollen season; 3) sinus bradycardia and greater than first degree block; 4) cardiogenic shock; 5) right ventricular failure secondary to pulmonary hypertension; 6) congestive heart failure (see WARNINGS) unless the failure is secondary to a tachyarrhythmia treatable with INDERAL; 7) in patients on adrenergic-augmenting psychotropic drugs (including MAO inhibitors), and during the two week withdrawal period from such drugs.

WARNINGS

CARDIAC FAILURE: Sympathetic stimulation is a vital component supporting circulatory function in congestive heart failure, and inhibition with beta-blockade always carries the potential hazard of further depressing myocardial contractility and precipitating cardiac failure. INDERAL acts selectively without abolishing the inotropic action of digitalis on the heart muscle (*i.e.*, that of supporting the strength of myocardial contractions). In patients already receiving digitalis, the positive inotropic action of digitalis may be reduced by INDERAL's negative inotropic effect. The effects of INDERAL and digitalis are additive in depressing AV conduction.

IN PATIENTS WITHOUT A HISTORY OF CARDIAC FAILURE, continued depression of the myocardium over a period of time can, in some cases, lead to cardiac failure. In rare instances, this has been observed during INDERAL therapy. Therefore, at the first sign or symptom of impending cardiac failure, patients should be fully digitalized and/or given a diuretic, and the response observed closely: a) if cardiac failure continues, despite adequate digitalization and diuretic therapy, INDERAL therapy should be immediately withdrawn; b) if tachyarrhythmia is being controlled, patients should be maintained on combined therapy and the patient closely followed until threat of cardiac failure is over.

IN PATIENTS WITH ANGINA PECTORIS, there have been reports of exacerbation of angina and, in some cases, myocardial infarction, following *abrupt* discontinuation of INDERAL therapy. Therefore, when discontinuance of INDERAL is planned the dosage should be gradually reduced and the patient carefully monitored. In addition, when INDERAL is prescribed for angina pectoris, the patient should be cautioned against interruption or cessation of therapy without the physician's advice. If INDERAL therapy is interrupted and exacerbation of angina occurs, it usually is advisable to reinstitute INDERAL therapy and take other measures appropriate for the management of unstable angina pectoris. Since coronary artery disease may be unrecognized, it may be prudent to follow the above advice in patients considered at risk of having occult atherosclerotic heart disease, who are given propranolol for other indications.

IN PATIENTS WITH THYROTOXICOSIS, possible deleterious effects from long term use have not been adequately appraised. Special consideration should be given to propranolol's potential for aggravating congestive heart failure. Propranolol may mask the clinical signs of developing or continuing hyperthyroidism or complications and give a false impression of improvement. Therefore, abrupt withdrawal of propranolol may be followed by an exacerbation of symptoms of hyperthyroidism, including thyroid storm. This is another reason for withdrawing propranolol slowly. Propranolol does not distort thyroid function tests.

IN PATIENTS WITH WOLFF-PARKINSON-WHITE SYNDROME, several cases have been reported in which, after propranolol, the tachycardia was replaced by a severe bradycardia requiring a demand pacemaker. In one case this resulted after an initial dose of 5 mg propranolol.

IN PATIENTS DURING ANESTHESIA with agents that require catecholamine release for maintenance of adequate cardiac function, beta blockade will impair the desired inotropic effect. Therefore, INDERAL should be titrated carefully when administered for arrhythmias occurring during anesthesia.

IN PATIENTS UNDERGOING MAJOR SURGERY, beta blockade impairs the ability of the heart to respond to reflex stimuli. For this reason, with the exception of [illegible] INDERAL should be withdrawn 48 hours prior to surgery, at which time all chemical and physiologic effects are gone according to available evidence. However, in case of emergency surgery, since INDERAL is a competitive inhibitor of beta receptor agonists, its effect can be reversed by administration of such agents, *e.g.*, isoproterenol or levarterenol. However, such patients may be subject to protracted severe hypotension. Difficulty in restarting and maintaining the heart beat has also been reported.

IN PATIENTS PRONE TO NONALLERGIC BRONCHOSPASM (*e.g.*, CHRONIC BRONCHITIS, EMPHYSEMA), INDERAL should be administered with caution since it may block bronchodilation produced by endogenous and exogenous catecholamine stimulation of beta receptors.

DIABETICS AND PATIENTS SUBJECT TO HYPOGLYCEMIA: Because of its beta-adrenergic blocking activity, INDERAL may prevent the appearance of premonitory signs and symptoms (pulse rate and pressure changes) of acute hypoglycemia. This is especiall important to keep in mind in patients with labile diabetes. Hypoglycemic attacks may be accompanied by a precipitous elevation of blood pressure.

USE IN PREGNANCY: The safe use of INDERAL in human pregnancy has not been estab lished. Use of any drug in pregnancy or women of childbearing potential requires that the possible risk to mother and/or fetus be weighed against the expected therapeutic benefit. Embryotoxic effects have been seen in animal studies at doses about 10 times the maximur recommended human dose.

PRECAUTIONS

Patients receiving catecholamine depleting drugs such as reserpine should be closely observed if INDERAL is administered. The added catecholamine blocking action of this drug may then produce an excessive reduction of the resting sympathetic nervous activity. Occasionally, the pharmacologic activity of INDERAL may produce hypotension and/or marked bradycardia resulting in vertigo, syncopal attacks, or orthostatic hypotension.

As with any new drug given over prolonged periods, laboratory parameters should be observed at regular intervals. The drug should be used with caution in patients with impaired renal or hepatic function.

ADVERSE REACTIONS

Cardiovascular: bradycardia; congestive heart failure; intensification of AV block; hypotension; paresthesia of hands; arterial insufficiency, usually of the Raynaud type; thrombocytopenic purpura

Central Nervous System: lightheadedness; mental depression manifested by insomnia, lassitude, weakness, fatigue; reversible mental depression progressing to catatonia; visual disturbances; hallucinations; an acute reversible syndrome characterized by disorientation for time and place, short term memory loss, emotional lability, slightly clouded sensorium, and decreased performance on neuropsychometrics

Gastrointestinal: nausea, vomiting, epigastric distress, abdominal cramping, diarrhea, constipation, mesenteric arterial thrombosis, ischemic colitis

Allergic: pharyngitis and agranulocytosis, erythematous rash, fever combined with achin and sore throat, laryngospasm and respiratory distress

Respiratory: bronchospasm

Hematologic: agranulocytosis, nonthrombocytopenic purpura, thrombocytopenic purpura

Miscellaneous: reversible alopecia. Oculomucocutaneous reactions involving the skin, serous membranes and conjunctivae reported for a beta blocker (practolol) have not been conclusively associated with propranolol.

Clinical Laboratory Test Findings: Elevated blood urea levels in patients with severe heart disease, elevated serum transaminase, alkaline phosphatase, lactate dehydrogenase

DOSAGE AND ADMINISTRATION

ORAL

HYPERTENSION—*Dosage must be individualized.* The usual initial dosage is 40 mg INDERAL twice daily, whether used alone or added to a diuretic. Dosage may be increased gradually until adequate blood pressure is achieved. The usual dosage is 160 to 480 mg pe day. In some instances a dosage of 640 mg may be required. The time needed for full hyper tensive response to a given dosage is variable and may range from a few days to several weeks.

While twice-daily dosing is effective and can maintain a reduction in blood pressure throughout the day, some patients, especially when lower doses are used, may experience a modest rise in blood pressure toward the end of the 12 hour dosing interval. This can be evaluated by measuring blood pressure near the end of the dosing interval to determine whether satisfactory control is being maintained throughout the day. If control is not adequate, a larger dose, or 3 times daily therapy may achieve better control.

PEDIATRIC DOSAGE

At this time the data on the use of the drug in this age group are too limited to permit adequate directions for use.

INTRAVENOUS

The intravenous administration of INDERAL has not been evaluated adequately in the management of hypertensive emergencies.

OVERDOSAGE OR EXAGGERATED RESPONSE

IN THE EVENT OF OVERDOSAGE OR EXAGGERATED RESPONSE, THE FOLLOWING MEASURES SHOULD BE EMPLOYED:

BRADYCARDIA—ADMINISTER ATROPINE (0.25 to 1.0 mg): IF THERE IS NO RESPONSE TO VAGAL BLOCKADE, ADMINISTER ISOPROTERENOL CAUTIOUSLY.

CARDIAC FAILURE—DIGITALIZATION AND DIURETICS.

HYPOTENSION—VASOPRESSORS, *e.g.*, LEVARTERENOL OR EPINEPHRINE (THERE I EVIDENCE THAT EPINEPHRINE IS THE DRUG OF CHOICE).

BRONCHOSPASM—ADMINISTER ISOPROTERENOL AND AMINOPHYLLINE.

HOW SUPPLIED

INDERAL
(propranolol hydrochloride)

TABLETS

No. 461—Each scored tablet contains 10 mg of propranolol hydrochloride, in bottles of 100 and 1,000. Also in unit dose package of 100.

No. 462—Each scored tablet contains 20 mg of propranolol hydrochloride, in bottles of 100 and 1,000. Also in unit dose package of 100.

No. 464—Each scored tablet contains 40 mg of propranolol hydrochloride, in bottles of 100 and 1,000. Also in unit dose package of 100.

No. 468—Each scored tablet contains 80 mg of propranolol hydrochloride, in bottles of 100 and 1,000. Also in unit dose package of 100.

INJECTABLE

No. 3265—Each ml contains 1 mg of propranolol hydrochloride in Water for Injection. The pH is adjusted with citric acid. Supplied as: 1 ml ampuls in boxes of 10.

Platelet Function in Hypertension and Effect of Therapy

JAWAHAR MEHTA, MD, FACC
PAULETTE MEHTA, MD

Gainesville, Florida

Platelet function was evaluated in 10 hypertensive and 11 normal subjects. In the placebo phase, the plasma beta thromboglobulin level (an index of platelet activation in vivo) was significantly ($p < 0.01$) higher in the hypertensive than in the normal subjects; other tests of platelet function gave similar results in the two groups. After control of blood pressure with lofexidine (a centrally acting imidazoline derivative), plasma beta thromboglobulin levels decreased in 9 of the 10 hypertensive patients, but increased in one who showed no change in blood pressure. These studies suggest that enhanced platelet activation in primary hypertension may be associated with increased vascular resistance.

Platelet dysfunction has been observed in several vascular disorders.[1–4] An increase in in vivo platelet aggregation may lead to impeded blood flow[5] and subsequent manifestations of tissue ischemia such as myocardial infarction[6,7] and cerebrovascular accidents.[3,8] Recently, it was proposed[9] that enhanced formation of platelet aggregates in the peripheral vessels may be a mechanism of increased vascular resistance. Platelet aggregation inhibitory effects of certain pharmacologic agents that decrease vascular resistance may in part be a mechanism of their beneficial action.[9,10] Poplawski et al.[11] demonstrated increased platelet adhesiveness in hypertensive subjects. In other studies,[12,13] in vitro platelet aggregation was also increased in hypertensive compared with normal subjects. The present study was conducted in a select group of hypertensive subjects to examine further different variables of platelet function in hypertension. The effects of antihypertensive therapy on alterations in platelet function were also evaluated.

Methods

Study subjects: Ten men aged 24 to 67 years (mean 50 ± 5) with documented primary hypertension of 6 months' to 4 years' duration were studied. The patients were included only if diastolic blood pressure was over 90 mm Hg on multiple examinations after discontinuation of any previous treatment with antihypertensive medications or diuretic drugs, or both, for at least 2 weeks. During this period, the patients were given a placebo capsule containing no active medication and followed up to document the presence of hypertension (placebo phase). Patients with clinical evidence of vascular disease, diabetes mellitus, gout or renal, hepatic or pulmonary dysfunction were excluded from the study. Particular attention was given to evaluation of renal function, because impaired renal function may affect certain variables of platelet function.[14] All patients gave informed consent before entering the study. The patients were asked not to take any platelet-active drug or diuretic agent during the placebo phase or subsequent drug study period.

After *documentation of hypertension*, each patient was started on treatment with lofexidine, a centrally acting imidazoline derivative antihypertensive agent,[15–17] 0.1 mg twice daily. The patients were followed up each week for control of blood pressure. The dose of medication was increased to a maximum of 0.3 mg twice daily to achieve adequate control of blood pressure (drug study phase).

From the Divisions of Cardiology and Hematology/Oncology, Departments of Medicine and Pediatrics, University of Florida, Shands Teaching Hospital and Veterans Administration Medical Center, Gainesville, Florida. This study was supported in part by the American Heart Association, Florida Affiliate, Palm Beach County Chapter, West Palm Beach, Florida, and by Merrell Research Laboratories, Cincinnati, Ohio. Manuscript received May 27, 1980; revised manuscript received August 26, 1980, accepted September 9, 1980.

Address for reprints: Jawahar Mehta, MD, Box J-277, JHM Health Center, University of Florida, Gainesville, Florida 32610.

Platelet function studies were also performed on one occasion in 11 other age- and sex-matched normal subjects. No normal subject had taken a platelet-active drug in the preceding 2 weeks.

Platelet studies: Platelet studies performed in the hypertensive patients included quantitation of aggregation responses to epinephrine and adenosine diphosphate (ADP) by light transmission as described previously.[4,18] Circulating platelet aggregates were evaluated by the method of Wu and Hoak.[1] Platelet sizing was done using an optical linear micrometer on 500 cells.[19] Platelet counts were done by phase microscopy after lysis of red cells with procaine hydrochloride.[20]

Plasma beta thromboglobulin assay was performed by radioimmunoassay.[2,21,22] Whole blood (2.5 ml) was collected using a 20 gauge, 1 inch (2.5 cm) needle and polystyrene syringe. A good venipuncture with freely flowing blood was obtained. Immediately after collection the needle was removed from the syringe and blood transferred gently to a precooled labeled sampling tube supplied with the kit. The tube was inverted three times and immediately cooled by placing it in a rack in a cooling bath. The sample was centrifuged at 4° C for 30 minutes. Centrifugation was carried out within 1 hour after collection. After centrifugation the top 0.5 ml was pipetted with a disposable plastic tip into a separately labeled specimen tube. The sample was stored at −20° C for a maximum of 3 weeks. Samples were thawed and mixed well before use. Aliquots of 50 μliter of reconstituted standards and of patient blood samples were pipetted into assay tubes. Aliquots of 200 μliter of beta thromboglobulin–iodine-125 solution and of 200 μliter of anti–beta thromboglobulin serum solution were mixed and whirled in the tubes. The tubes were incubated at room temperature for 1 hour. Ammonium sulfate solution (500 μliter aliquots) was added to each of the assay tubes, after which the tubes were spun. Tubes were centrifuged for 15 minutes at 1000 *g*; they were then removed from the centrifuge and placed in decantation racks, and supernatant liquids were discarded. The precipitate remained undisturbed during this procedure. After draining of supernatant material, the precipitates were counted in a gamma counter. The concentration of beta thromboglobulin (ng/ml) was determined from a standard curve established from readings of radioactivity counts/second obtained from known samples with the kit.

These platelet studies were done during the placebo and the drug study phases in all patients. In all but one patient, the second set of platelet function studies were performed at the dose of lofexidine necessary for control of blood pressure. In one patient, blood pressure could not be controlled with the maximal dose of lofexidine, and platelet function studies were done while he was taking 0.6 mg of lofexidine per day.

Calculations: The data are expressed as mean ± standard error of the mean. Student's *t* test (paired and unpaired data) was used for statistical calculations. A p value less than 0.05 was considered significant.

TABLE I

Platelet Studies in Normal and Hypertensive Subjects

	Normal Subjects	Hypertensive Subjects	
		Placebo Phase	Drug Study Phase
Platelet counts (per mm^3)	275,000 ± 41,000	290,000 ± 32,000	257,000 ± 21,000
Platelet size (μ)	2.12 ± 0.04	2.0 ± 0.02	2.01 ± 0.03
Platelet aggregation (%)			
Epinephrine	72 ± 7	62 ± 11	66 ± 11
Adenosine diphosphate	70 ± 5	74 ± 4	75 ± 4
Circulating platelet aggregates (%)	7 ± 2	9 ± 3	8 ± 2
Plasma beta thromboglobulin (ng/ml)	42 ± 5	108 ± 21*	66 ± 10†

* $p < 0.01$, hypertensive subjects in placebo phase compared with normal subjects. † $p < 0.05$, hypertensive subjects in drug study phase compared with placebo phase.

Results

Blood pressure and heart rate: In the placebo phase, blood pressure in the hypertensive patients was 144 ± 4/96 ± 1 mm Hg (systolic/diastolic) in the sitting position. The heart rate was 76 ± 3 beats/min. After 2 to 6 weeks (mean 3 ± 1 week) of therapy with lofexidine (mean dose 0.5 ± 0.1 mg/day), blood pressure in the entire group of patients had gradually decreased to 122 ± 4/84 ± 2 mm Hg ($p < 0.001$ compared with the placebo phase). Heart rate was unchanged at 71 ± 3 beats/min (difference not significant [NS]). Blood pressure was uncontrolled in one patient at the maximal dose of lofexidine.

Platelet studies: Results of the platelet function studies in normal and hypertensive subjects are summarized in Table I. Platelet counts and size were similar in the two groups. Platelet aggregation in response to the addition of epinephrine and ADP in hypertensive patients was comparable with that in the normal subjects. Circulating platelet aggregates were in the normal range in all but one of the hypertensive patients, but the mean values were similar to those in the normal subjects.

Plasma beta thromboglobulin levels ranged from 21 to 230 ng/ml (mean 108 ± 21) in hypertensive patients compared with 42 ± 5 ng/ml (range 35 to 55) in the normal subjects. This difference was statistically significant ($p < 0.01$). Of the 10 hypertensive patients, 7 had a beta thromboglobulin level 2 standard deviations or more above the normal range, whereas 3 had a level in the normal range. The plasma beta thromboglobulin level did not correlate with blood pressure or with degree of platelet aggregation, platelet counts or size. Nevertheless, one patient with abnormally high circulating platelet aggregates (27 percent) had a very high level of plasma beta thromboglobulin (230 ng/ml).

With therapy, platelet counts increased in three patients and decreased in seven, but the change was not significant. Similarly, platelet size was not altered by drug therapy. Maximal platelet aggregation in response to epinephrine and ADP and circulating platelet aggregates were not affected by lofexidine therapy. After treatment with lofexidine, the plasma beta thromboglobulin level decreased ($p < 0.05$) in all but one patient (Fig. 1). The patient whose beta thromboglobulin level increased (from 77 to 129 ng/ml) had no change in blood pressure. The decrease in plasma beta thromboglobulin

level was most marked in the patients with the highest values in the placebo phase, whereas those with minimal elevation of beta thromboglobulin levels had only a slight decrease. There was no correlation between change in blood pressure and plasma beta thromboglobulin level.

Effect of lofexidine on renal function: In the placebo phase, blood urea nitrogen (range 10 to 23 mg/100 ml, mean 15 ± 3) and serum creatinine (range 0.3 to 1.2 mg/100 ml, mean 0.7 ± 0.1) were within the normal range in all study patients. With therapy, no significant changes occurred either in blood urea nitrogen (range 9 to 25 mg/100 ml, mean 14 ± 3) or in serum creatinine (range 0.6 to 1.1, mean 0.8 ± 0.1). Similarly, serum electrolytes were unaffected by lofexidine therapy. Urinalysis in the placebo and drug study phases revealed no evidence of a significant effect of lofexidine on renal function.

Discussion

The results of this study show that plasma beta thromboglobulin levels are significantly increased in certain patients with hypertension. All other variables of platelet function such as aggregation responses to epinephrine and ADP, circulating platelet aggregates and platelet counts and size are within the normal range.

Plasma beta thromboglobulin in hypertension: This secretory product of platelets is released by their alpha granules during the release reaction. In several studies,[2,23] plasma beta thromboglobulin levels were correlated with the state of platelet activation and survival in vivo. In another study,[22] plasma beta thromboglobulin levels and platelet factor 4 were found to be increased, indicating platelet activation in a select group of patients with vascular disease. A close correlation between the two tests of platelet function was found. In contrast, in vitro platelet aggregation and in vivo circulating platelet aggregates have produced variable indexes of platelet activation in states of vascular disease.[24,25] Platelet counts and size provide a crude index of platelet kinetics and activation.

In the present study, we chose a small but select group of patients who had not taken any platelet-active or antihypertensive agent during the preceding 2 weeks. Blood pressure in each of the subjects was clearly abnormally increased and there was no evidence of renal impairment. A state of enhanced in vivo platelet activation as reflected by an increase in the plasma beta thromboglobulin level in 7 of 10 patients suggests a relation between platelets and blood pressure. Previous studies have shown increased platelet adhesiveness[11] and platelet aggregation[13,14] in hypertensive patients. However, the results of tests of platelet adhesion may vary, and the method itself may not be very reproducible.[26] Nevertheless, elevated levels of plasma beta thromboglobulin may indicate platelet activation in the hypertensive state which may not be detected by other laboratory tests of platelet function. Whether platelet activation is a cause of increased resistance or a result

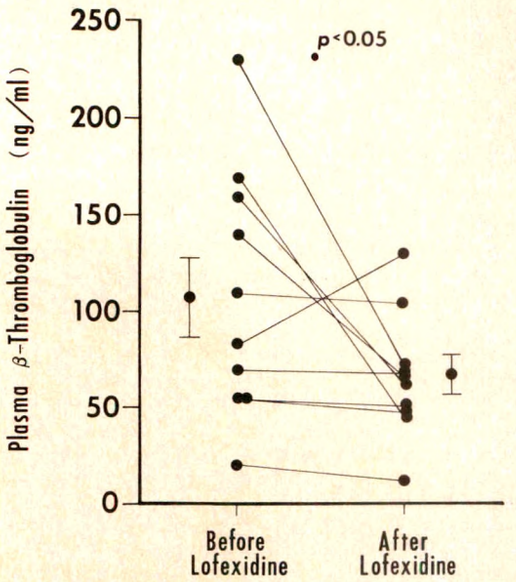

FIGURE 1. Effect of antihypertensive therapy on plasma beta thromboglobulin levels in 10 hypertensive patients.

of abnormal vascular tone in these patients is not clear from this study. Increased catecholamines in primary hypertension as documented by Vlachakis and Aledort[12] could account for enhanced platelet release reaction, but circulating catecholamine levels even in pathologic situations are not usually high enough to induce aggregation in themselves. However, they may contribute to the potentiation of aggregation and release reaction.

Antihypertensive agents and platelets: Several drugs used in the treatment of hypertension, such as phentolamine, propranolol and nitroprusside, have platelet aggregation inhibitory effects.[27–29] Lofexidine's major antihypertensive action is at the level of the central nervous system.[15–17] Lofexidine produces biochemical changes consistent with a central sympathomimetic effect.[30] In one study, epinephrine-induced platelet aggregation was inhibited by lofexidine,[31] implying its actions on platelet alpha$_2$ adrenergic receptors. In our patients, we found no specific alteration in circulating platelet aggregates or aggregation responses to epinephrine and ADP during therapy with lofexidine. However, this plasma beta thromboglobulin level decreased as blood pressure was controlled with lofexidine, although in one patient the plasma level increased while blood pressure was unchanged. It is not clear whether the decrease in plasma beta thromboglobulin level was due to a decrease in blood pressure or was directly related to lofexidine. It is conceivable that modulation of alpha adrenergic receptors with lofexidine results in a decrease in platelet activation and subsequently normal platelet release reaction. Although we did not measure the circulating catecholamines, it is possible that a decrease in plasma catecholamines may have been responsible for changes in plasma beta

ıromboglobulin levels. In several other studies,[13,32,33] lasma catecholamines were reported to increase after ıerapy of hypertension. Whether a similar phenomeon occurs with lofexidine as well is not known.

Clinical implications: Our observations suggest that latelet activation may be related to the hypertensive ;ate. Further studies are needed to determine whether ıhibition of platelet activation with platelet-suppressive agents ameliorates some of the clinical sequelae ı patients with hypertension. A recent report[34] suggests ıat modulation of platelet function and prostaglandin pathways by drugs like indomethacin may alter activity of potent antihypertensive agents such as hydralazine. Measuring the plasma beta thromboglobulin level in patients with hypertension as a means of assessing platelet contribution provides an avenue for further studies in this area.

Seventy-three hypertensive patients were evaluated with M mode and two dimensional echocardiography. Left ventricular hypertrophy was found in 37 patients (51 percent); 29 had concentric hypertrophy and the remaining 8 had disproportionate septal thickening. Factors that did not influence the distribution of patients in the group with left ventricular hypertrophy and normal subjects included (1) duration of hypertension, (2) level of blood pressure, (3) age, (4) body surface area, and (5) race. More of the patients who had a normal left ventricular mass (32 or 89 percent) than of those who had hypertrophy (22 or 59 percent) were receiving two or more antihypertensive drugs. Electrocardiography was very insensitive in identifying left ventricular hypertrophy in these patients. The presence of increased left ventricular mass was associated with a greater incidence of other target organ disease.

The importance of determining left ventricular size and performance in patients with systemic hypertension is well recognized by clinicians. Significant cardiac manifestations of target organ involvement secondary to hypertension include myocardial infarction, left ventricular hypertrophy and left ventricular dysfunction. Traditionally electrocardiography has been considered a reliable method and a more sensitive tool than chest roentgenography to detect left ventricular hypertrophy.[1,2]

In recent years the application of M mode echocardiography has proved the most reliable method for measuring left ventricular wall thickness and function in hypertensive patients.[3–10] However, its application has been restricted by the inherent limitations of the M mode single dimension method. Furthermore, it is difficult to interpret the effects of hypertension on wall thickness or left ventricular function without first excluding wall motion abnormalities caused by previous myocardial infarction.

Although cardiac hypertrophy is one of the fundamental mechanisms of adaptation to abnormal loading conditions, studies on the effects of hypertrophy on myocardial performance are controversial. Sasayama et al.[11] found that the linear relation between left ventricular diameter and wall stress at the end of ejection was the same in control and hypertrophied dog hearts. These investigators concluded that in successful adaptation to the pressure overload, hypertrophy did not produce intrinsic depression of the myocardial inotropic state. Takahashi et al.[12] reported that myocardial contractility may be depressed in hypertensive patients with advanced left ventricular hypertrophy; in seven patients the end-systolic wall stress-diameter relation was shifted to the right. Karliner et al.[6] concluded that the hypertrophic response to a chronic increase in systemic arterial pressure did not result in depression of the basal inotropic state of the left ventricle.

This study was undertaken to investigate the cardiac manifestations of essential hypertension by M mode and two dimensional echocardiography with special reference to left ventricular anatomy and function and to correlate these findings with the other clinical features and target organ involvement.

Methods

Study patients: The study group consisted of 82 patients who were referred from a hypertension clinic where clinical evaluation and therapeutic control of elevated blood pressure had been accomplished. The population was unselected except that patients with evidence of previous myocardial infarction, valvular heart disease or cardiomyopathy were excluded. Furthermore, only patients who had technically satisfactory M mode and two dimensional echocardiograms were included. The final study group comprised 73 patients, 35 men and 38 women ranging in age from 28 to 85 years (mean 57). All except two patients were receiving antihypertensive treatment at the time of the study. History, physical examination, electrocardiography and determination of serum electrolytes and creatinine were conducted on the same day that echocardiography was performed.

Echocardiographic studies: Combined M mode and two dimensional echocardiographic studies were performed with a Varian V-3000 wide angle, phased array system (Varian Associates, Palo Alto, California) interfaced with a Sanyo 7100 videotape recorder. All patients were positioned in a 30° left lateral decubitus position with slight elevation of the head. Comprehensive two dimensional tomographic planes were employed with multiple parasternal views of the left ventricle in long and short axes, apical four chamber and long axis views, and subcostal four chamber and short axis views. After positioning of the cursor through the interventricular septum and posterior wall at the level of the chordae tendineae, simultaneous M mode and two dimensional recordings were obtained from the parasternal transducer position in both long and short axis views of the left ventricle (Fig. 1). All views were carefully evaluated by at least two observers for evidence of any regional wall motion abnormality to be certain that all patients with previous myocardial infarction were excluded from the study. Four patients were excluded because the two dimensional studies were technically inadequate to make accurate wall thickness measurements. M mode or two dimensional echographic studies, or both, were utilized in the remaining 73 patients to determine the thickness of the interventricular septum, posterior left ventricular wall, cross-sectional area of the left ventricle and percent fractional shortening.

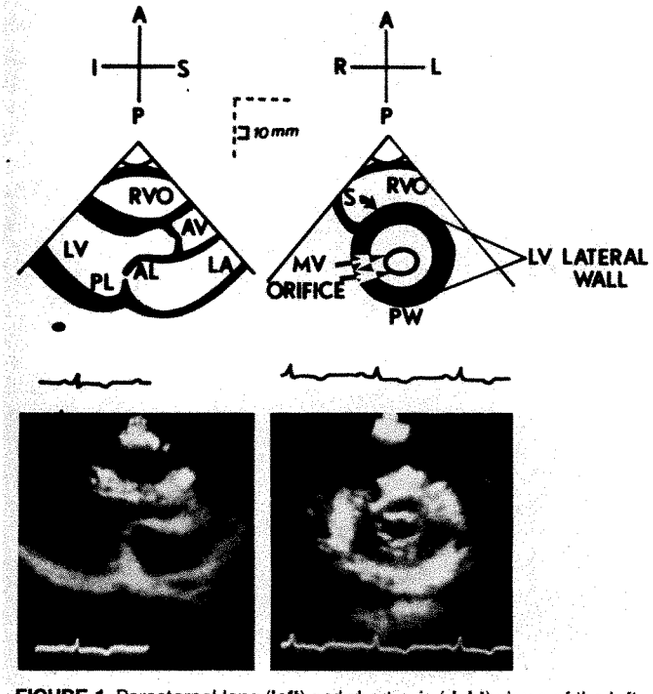

FIGURE 1. Parasternal long (**left**) and short axis (**right**) views of the left ventricle (LV). Although multiple views of the left ventricle were obtained with two dimensional echocardiographic imaging, these two tomographic planes were the most reliable for recording M mode studies at the tips of the mitral leaflets or through the chordae tendineae. A = anterior; AL = anterior mitral leaflet; AV = aortic valve; I = inferior; L = left; LA = left atrium; MV = mitral valve; P = posterior; PL = posterior mitral leaflet; PW = posterior wall of the left ventricle; R = right; RVO = right ventricular outflow tract; S = septum and superior.

Echocardiographic measurements: The left ventricular posterior wall and septum were measured at the time of atrial depolarization before the onset of the *a* notch. The end-diastolic dimension (EDD) of the left ventricle was determined at the level of the chordae tendineae at the peak of the R wave from the electrocardiogram, and the end-systolic dimension (ESD) was measured at the minimal cavity diameter from the same beat. M mode measurements were taken by the leading edge to leading edge technique as recommended by the American Society of Echocardiography. All measurements were averaged to the closest 1 mm from three good quality cardiac cycles. All M mode and two dimensional studies were interpreted simultaneously by two investigators (A.D.H. and A.C.) without knowledge of the patients' clinical information. Whenever discordance exceeded 1 mm between M mode and two dimensional measurments, the two dimensional study was used as a quality control check on the accuracy of the M mode calculations. The loss of endocardial reflectances from both the septum and the posterior wall may contribute to underestimating the respective wall thicknesses without the additional use of two dimensional imaging (Fig. 2).

Calculations from echocardiographic measurements were: (1) percent fractional shortening (% FS) = [(EDD − ESD)/EDD] × 100, and (2) cross-sectional area (CSA) in square centimeters, calculated as an index of left ventricular mass[13] as follows: $CSA = \pi [(EDD + S_D + PW_D)/2] - \pi [(EDD/2)^2]$, where S_D = diastolic thickness of the ventricular septum and PW_D = diastolic thickness of the posterior wall of the left ventricle.

Normal criteria for left ventricular measurements and derived calculations were as follows: (1) S_D and PW_D, 11 mm or less; (2) CSA, 21 cm^2 or less; (3) EDD, 54 to 57 mm or less depending on body surface area; and (4) % FS, 31 or greater.

Clinical features and groups: In addition to the echocardiographic and laboratory studies, the following clinical information was also recorded: (1) duration of hypertension (less than 5 years, 5 to 15 years, or greater than 15 years); (2) number, type and dosage of antihypertensive drugs; (3) standard cuff blood pressure; (4) history of stroke or recurrent transient cerebral ischemia; and (5) fundoscopic findings, graded 0 to IV using standard criteria for hypertensive retinopathy.

The 73 patients were classified into two groups: Group I included patients with a normal left ventricular wall thickness, that is, a posterior wall thickness of 11 mm or less; and Group II included those with left ventricular hypertrophy, that is, a posterior wall thickness of 12 mm or greater.

Results

Left ventricular hypertrophy: Of the 73 patients studied, 37 (51 percent) had left ventricular hypertrophy with a mean thickness of the posterior wall and interventricular septum of 13.4 and 14.2 mm, respectively (Table I). Twenty-nine of these patients had

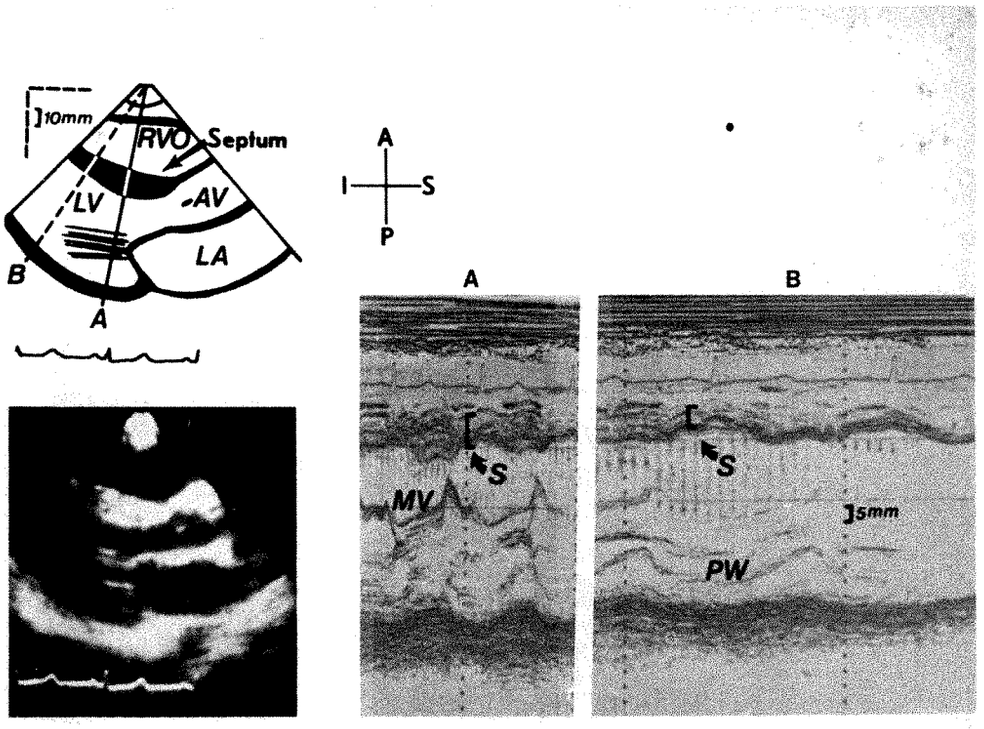

FIGURE 2. Two-dimensional echocardiogram in parasternal left ventricular (LV) long axis view (**left**) with corresponding M mode echocardiogram (**right**) showing the M mode cursor intersecting the septum at two different levels. The M mode recording at the tip of the mitral leaflets (**A**) reveals the correct thickness of the septum; the M mode recording in **B** demonstrates the apparent thickness of the septum to be much thinner due to echographic "dropout" of the reflectances from the right side. Abbreviations as in Figure 1.

concentric hypertrophy and 8 had disproportionate septal thickening. Group I consisted of 36 patients (49 percent) with a normal wall thickness; in this group the mean thickness of the posterior wall and interventricular septum was 9.9 and 10.5 mm, respectively. A significant difference existed in left ventricular mass as determined by cross-sectional area measurements of the left ventricle in the two groups: 16.4 ± 2.6 cm^2 in Group I versus 26.8 ± 3.2 cm^2 in Group II ($p < 0.01$) (Table I, Fig. 2).

There was no significant difference in age, body surface area or race in the two groups (Table II). However, there was a significantly greater proportion of women in Group I (20 versus 16) and a greater proportion of men in Group II (26 versus 11) ($p < 0.05$).

Blood pressure: Most of the patients demonstrated satisfactory control of blood pressure with the antihypertensive therapy being administered at the time of the study. Furthermore, no significant difference in blood pressure existed in the normal subjects in Group I and the group with left ventricular hypertrophy; mean blood pressure in Group I was 142/87 ± 15/11 mm Hg compared with 154/88 ± 26/24 in Group II (Table II). Seven (19 percent) of the 36 patients without left ventricular hypertrophy and 12 (32 percent) of the 37 patients with hypertrophy had a blood pressure of 160/90 mm Hg or greater.

Duration of hypertension: The duration of hypertension did not influence the distribution of patients in the two groups. In contrast to findings reported by Ross et al.,[7] no significant difference was found in the two groups when the patients were classified on the basis of the duration of hypertension (Table II). A history of hypertension longer than 5 years existed in 24 (67 percent) of the 36 normal patients in Group I and in 27 (73 percent) of the 37 patients in Group II. Of the 37 patients with left ventricular hypertrophy, 27 had had hypertension for more than 5 years and 10 for less than 5 years.

Treatment: Although longer duration of hypertension was not associated with a greater incidence of left ventricular hypertrophy, a significantly greater proportion of the normal subjects in Group I (32 of 36 or 89 percent) than of patients in Group II (22 of 37 or 59 percent) were receiving two or more antihypertensive drugs ($p < 0.05$). Nine patients without hypertrophy (25 percent) and 6 patients with hypertrophy (16 percent) were receiving beta adremergic blocking agents; 26 patients in Group I (72 percent) and 17 patients in Group II (46 percent) were receiving diuretic therapy.

Left ventricular size and function: Left ventricular cavity dimensions were normal in all but one patient.

TABLE I

Left Ventricular Anatomy and Function in 73 Hypertensive Patients

	36 Patients With Normal PW Thickness*	37 Patients With LVH*
PW thickness (mm)	9–11 (9.9)†	12–18 (13.4)

Patients with DST (n)	3	8
CSA (cm^2)	12.7–26.5 (16.4)†	17.6–41.3 (26.8)
EDD (mm)	37–62 (45)	39–55 (47)
% FS	31–50 (39.5)	26–50 (37.1)

* Mean values in parentheses. † $p < 0.01$.

CSA = cross-sectional area; DST = disproportionate septal thickening; EDD = end-diastolic dimension; IVS = interventricular septum; LVH = left ventricular hypertrophy; % FS = percent fractional shortening; PW = posterior wall.

TABLE II

Clinical Features of 73 Patients With Hypertension

	36 Patients With Normal PW Thickness	37 Patients With LVH
Mean age (yr)	57 ± 12	59 ± 13
Mean BSA (yr)	1.84	1.71
Sex (M/F ratio)	16:20*	26:11
Race (W/B ratio)	34:2	34:3
History of hypertension		
5 yr or less	12	10
Greater than 5 yr	24	27
Blood pressure (mm Hg)		
Range	120–170/70–120	120–240/80–120†
Mean	142/87	154/88
Two or more antihypertensive drugs	32*	22

* $p < 0.05$. † Only one patient had a systolic pressure greater than 180 mm Hg.

B = black; BSA = body surface area; F = female; LVH = left ventricular hypertrophy; M = male; PW = posterior wall; W = white.

The exception was a 47 year old man with a body surface area of 2.2 m^2, a diastolic dimension of 62 mm, percent fractional shortening of 31, septal and posterior wall thicknesses of 10 mm each, blood pressure of 170/120 mm Hg and grade III hypertensive retinopathy; he was on triple drug therapy and had no evidence of left ventricular hypertrophy on electrocardiography. Left ventricular function was normal in all patients in Group I, whereas four patients (11 percent) in Group II with hypertrophy had reduced fractional shortening and diffuse hypokinesia observed on two dimensional echocardiography. There was no left ventricular cavity dilatation in any of the patients with hypertrophy or decreased function.

Electrocardiographic findings: All patients had sinus rhythm except one with atrial fibrillation. Three patients had left anterior fascicular block; all others had a normal frontal plane QRS axis. Nonspecific ST-T wave changes occurred with the same frequency in both patient groups: in 8 (22 percent) of 36 patients in Group I and in 9 (24 percent) of 37 in Group II. With use of the criterion for left ventricular hypertrophy of an R wave in lead aVL of 11 mm or greater, only 4 (11 percent) of the 37 patients in Group II had a positive result, but 2 additional patients in Group I demonstrated left ventricular hypertrophy on electrocardiography. With use of the Sokoloff criteria (S in V_1 + R in V_5 of 35 mm or greater), 7 (19 percent) of 37 patients in Group II

TABLE III

Electrocardiogram in 73 Patients With Hypertension

ECG Criteria of LVH	36 Patients With Normal PW Thickness	37 Patients With LVH
R in aVL ≥ 11 mm	2	4
S in V_1 + R in V_5 ≥ 35 mm	0	7
S in V_1 + R in V_5 + R in aVL	2	9

ECG = electrocardiographic; LVH = left ventricular hypertrophy; PW = posterior wall.

TABLE IV

Evidence of Target Organ Disease in 73 Patients With Hypertension

	36 Patients With Normal PW Thickness	37 Patients With LVH
History of stroke (n)	3	6
Hypertensive retinopathy (grades II or III) (n)	13*	25
Mean serum creatinine (mg/100 ml)	1.09 ± 0.5*	1.58 ± 0.9

* $p < 0.05$.

LVH = left ventricular hypertrophy; PW = posterior wall.

demonstrated electrocardiographic evidence of left ventricular hypertrophy and there were no false positive results in Group I (Table III).

Target organ disease: Although the difference was not statistically significant, six patients with hypertrophy and three patients with normal wall thickness had had a stroke. Patients in Group II with hypertrophy had significantly more hypertensive retinopathy (Table IV); 12 (32 percent) of 37 had grade 0 or I and 25 (68 percent) had grade II or III hypertensive retinopathy. In contrast, 23 (63 percent) of the 36 patients in Group I with normal wall thickness had grade 0 or I retinal findings and only 13 (37 percent) had grade II or III hypertensive retinopathy changes. Impairment of renal function was also more common in Group II; 22 patients (59 percent) in Group II had an elevated serum creatinine level (1.2 mg/100 ml or greater), compared with only 10 patients (28 percent) in Group I ($p < 0.05$) (Table IV).

Discussion

Left Ventricular Hypertrophy

Salcedo et al.[14] reported that two dimensional echocardiography was more accurate than M mode tracings in calculating left ventricular mass in dogs with experimental hypertension. These investigators observed that M mode studies underestimated the thickness of both the ventricular septum and the posterior wall; they also found the two dimensional echocardiogram particularly useful in defining the presence of left ventricular hypertrophy in dogs when there was increased thickness of the anterolateral wall with no significant change in the septal and posterior walls. No clinical studies have been reported in which two dimensional echocardiography has been employed as a quality control check for M mode derivations of left ventricular wall thickness and mass. We not only used two dimensional imaging to monitor the accuracy of the M mode measurements, but we also excluded patients who had segmental wall motion abnormalities without other clinical evidence of previous myocardial infarction. Satisfactory M mode imaging was difficult in several patients in the study group, and without the additional information from two dimensional echocardiography, they would have been excluded. One of the technical problems that contributed to echographic "dropout" of the ventricular sep-

tum with loss of true septal thickness on the recording is attributed to the echographic beam intersecting the septum obliquely because the transducer had to be positioned inferiorly along the left sternal border.

A posterior wall thickness of 12 mm or greater was established as the criterion for left ventricular hypertrophy. We employed the formula used by Sasayama et al.[13] to determine the cross-sectional area of the left ventricle. With use of the cross-sectional area as an index of left ventricular mass, 21 cm^2 was the most appropriate value to separate normal patients from those with increased left ventricular mass (Fig. 3). The three patients who had a mild increase in posterior wall thickness had sufficiently small end-diastolic dimensions that the resultant cross-sectional areas were normal; in contrast, one patient who had a slight increase in cross-sectional area (23 cm^2) with a posterior wall thickness of 11 mm had an end-diastolic dimension at the upper limit of normal. These data reveal that posterior wall thickness is an acceptably good indicator of left ventricular mass as long as the chamber size is normal; however, as the cavity size enlarges, the posterior wall thickness measurement should be expected to underestimate mass.

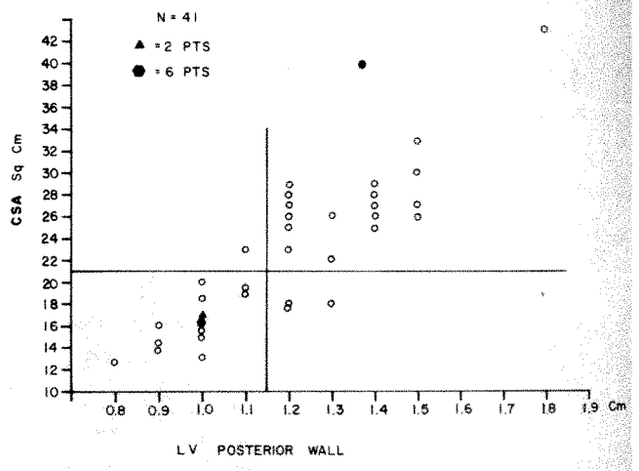

FIGURE 3. The left ventricular (LV) posterior wall thickness is correlated with the cross-sectional area (CSA), which is an index of left ventricular mass. PTS = patients.

Disproportionate Septal Thickening

An association of disproportionate septal thickening (that is, a ventricular septal to left ventricular posterior wall thickness ratio of 1.3 or greater) and hypertension has previously been reported; however, most studies have noted a low incidence rate of 4 to 10 percent.[4,8,10] Our findings were not significantly different: 11 (15 percent) of 73 patients showed disproportionate septal thickening (Table I). Three of the 11 patients had normal thickness of the posterior wall. We found no relation between the presence of disproportionate septal thickening and the duration of the hypertension or the degree of blood pressure elevation. Whether the presence of disproportionate thickening of the septum in hypertensive patients represents an atypical response to the increased afterload or is a coincidental occurrence is not clear. Disproportionate septal hypertrophy has been reported in a much larger proportion (30 to 47 percent) of hypertensive subjects.[15–17] One possible explanation of such a wide range (4 to 47 percent) is measurement error because all determinations were obtained from the M mode scan without the additional benefit of two dimensional imaging. If the M mode echocardiographic beam is directed at a tangent through the septum, the resultant recording may show a falsely thick septum; echo "dropout" (Fig. 2), on the other hand, may cause septal thickness to be underestimated. The combined use of M mode and two dimensional echocardiography should greatly reduce or eliminate the potential for such M mode measurement errors.

Left Ventricular Function

Several years ago Meerson[18] described a pathophysiologic sequence for the development of left ventricular hypertrophy. He reported that the immediate response to a hypertrophy-inducing stimulus imposed on a normally functioning heart was one of physiologic hyperfunction associated with an increase in myocardial protein systhesis. Thus, even before the hypertrophic process causes an increase in left ventricular mass, myocardial function is enhanced in order to overcome its increased pressure work load. This enchancement of left ventricular performance may be observed in patients with aortic stenosis as well as in hypertensive patients.[19]

The end-systolic relations between wall stress and left ventricular diameter did not differ in normal and hypertrophied ventricles.[11] Karliner et al.[6] reported that wall stress in hypertensive patients with left ventricular hypertrophy did not differ significantly from that obtained in normal subjects under basal conditions (167 ± 8.7 compared with 172 ± 6.6 g/cm^2).

Left ventricular ejection phase indexes, including cardiac index, ejection fraction, mean velocity of circumferential fiber shortening and mean normalized systolic ejection rate, were found to be normal in patients with hypertensive hypertrophy.[20] Left ventricular function was impaired only when regional contraction abnormalities or ventricular dilatation, or both, occurred and was inversely related to both cardiac size and systolic wall stress. Strauer[20] concluded that the appropriateness of left ventricular hypertrophy, as a result of mass to volume ratio and stress, is a major determinant of left ventricular performance and of myocardial oxygen consumption. Furthermore, he described two more types of inappropriate left ventricular hypertrophy in patients with hypertensive heart disease: (1) low stress hypertrophy, with an increased mass to volume ratio, normal left ventricular function and normal or reduced myocardial oxygen consumption, and (2) high stress hypertrophy, with normal or low mass to volume ratio, impaired left ventricular function and increased myocardial oxygen consumption. Karliner[6] and Takahashi[12] and their co-workers found no difference in the velocity of circumferential fiber shortening in hypertensive and normal groups. In contrast, however, Frohlich et al.[21] described a reduction in left ventricular

performance in hypertensive patients with left ventricular hypertrophy.

Guazzi et al.[9] *observed a similar functional pattern of the right and left ventricles in hypertensive patients;* this parallel functional pattern of both ventricles suggests a functional interdependence of the two sides that cannot be interpreted in terms of afterload but is probably best explained by changes in the contractile state of the whole heart. Olivari et al.[22] noted that systemic hypertension was associated with mild increases in pulmonary arterial pressure and pulmonary arterial resistance that were not necessarily a consequence of impaired left ventricular function.

Of the 73 hypertensive patients in our study, 4 (5 percent) had decreased left ventricular performance evidenced by fractional shortening of less than 31 percent and mild diffuse hypokinesia on two dimensional studies. None of these patients had left ventricular enlargement. It should be reemphasized that all hypertensive patients with known previous myocardial infarction or segmental wall motion abnormalities on the two dimensional echocardiographic examination were excluded from the study group; therefore the total number of those patients with reduced left ventricular function would be expected to be smaller.

Left Ventricular Wall Thickness: Clinical Correlations

Our findings support the finding of other investigators that echocardiography is the most sensitive clinical method to diagnose left ventricular hypertrophy and measure left ventricular mass. Because of the variability in ventricular septal thickness, the posterior wall is the preferred site to measure.

The small incidence of reduced left ventricular function in our study (4 of 73 patients) could be expected because all but 1 patient had had reasonably good control with therapy and all patients with previous myocardial infarction were excluded. A total of 5 of the original 82 patients referred for the study were excluded because of segmental wall motion abnormalities in the absence of historical or electrocardiographic evidence of previous myocardial infarction. No patient had abnormal left ventricular performance in the absence of left ventricular hypertrophy as determined by cross-sectional area. None of the four patients with reduced function had any enlargement of the left ventricular cavity. These four patients manifested clinical evidence of heart failure; however, no cardiomegaly was demonstrated by roentgenography.

There was a significantly greater proportion of men than of women with left ventricular hypertrophy ($p < 0.05$). Group I (normal subjects) and Group II (patients with hypertrophy) did not differ in age, body surface area or race. Furthermore, in contrast to the report of Ross et al.,[7] the duration of hypertension was not a significant factor in the development of hypertrophy. The mean blood pressure in the two groups did not differ: 142/87 mm Hg in Group I and 154/88 in Group II. A significantly greater number of patients in Group I were receiving two or more antihypertensive drugs ($p < 0.05$). This finding probably reflects better control of blood pressure in patients in Group I who are still without evidence of target organ damage to the heart. This should be a reassuring finding for both the physician and his hypertensive patient. As long as satisfactory control of blood pressure is being achieved, the use of an increasing number of antihypertensive drugs does not correlate with progression of left ventricular hypertrophy.

In light of how much reliability has traditionally been associated with electrocardiography in identifying left ventricular hypertrophy in hypertensive disease, it was disappointing to see how insensitive electrocardiography was in this study. Depending on which electrocardiographic criteria are used, the sensitivity of electrocardiography in diagnosing left ventricular hypertrophy in our patients in Group II ranged from 19 to 24 percent (Table III).

It is not surprising that left ventricular hypertrophy as a manifestation of target organ involvement is associated with a greater incidence of other target organ disease (Table IV). Higher levels of serum creatinine and more severe (grades II and III) hypertensive retinopathy were found in the group with hypertrophy ($p < 0.05$). Although the numbers were too small to have statistical significance, five patients in Group II versus three in Group I had an associated history of stroke.

In summary, combined M mode and two dimensional echocardiography is the most sensitive noninvasive method of measuring left ventricular wall thickness, mass and function. Approximately two thirds of patients with left ventricular hypertrophy will have evidence of significant hypertensive retinopathy or elevated serum creatinine.

INSTRUCTIONS FOR AUTHORS

The editors of THE AMERICAN JOURNAL OF CARDIOLOGY welcome concise articles devoted to cardiovascular disease. Articles must be contributed solely to THE AMERICAN JOURNAL OF CARDIOLOGY and become the property of the Publisher. The Publisher reserves copyright and renewal on all published material, and such material may not be reproduced in any form without the written permission of the Publisher. Statements in articles are the responsibility of the authors. Authors will assist the editors in the prompt processing of manuscripts if these instructions are followed:

THE WHOLE PAPER

- Address manuscript to Managing Editor, American Journal of Cardiology, 666 Fifth Ave., New York, NY 10103.
- Submit two copies of all elements of the article: text, references, legends, tables and figures.
- Arrange the paper in this order: (1) title page; (2) abstract; (3) text; (4) references; (5) legends; (6) tables; and (7) figures.
- Number all pages in above sequence, beginning with title page as 1, abstract as 2, etc.
- Type all matter: (1) on $8\frac{1}{2} \times 11$ opaque white bond paper; (2) in duplicate; (3) on one side of each sheet only; (4) double-space; (5) leave wide margins, all four sides.

THE TITLE PAGE

- Include first names, degrees and, where applicable, FACC for all authors.
- Provide a short running title of 3 to 6 words.
- Insert at bottom: name and address of institution from which work originated plus information about grants.
- Add at bottom the phrase "Address for reprints: . . ." followed by full name and address with zip code.

THE ABSTRACT

- Limit words as follows: 100 to 250 words for major articles; 50 to 100 words for case reports.
- Add at end of abstract: list of 2 to 6 key words and subjects for indexing.

THE TEXT

- Type in duplicate; double-space.
- Do not use abbreviations such as SVC, WPW: write out superior vena cava, Wolff-Parkinson-White.
- Abbreviate measurements (mm, kcal and the like) as recommended in *Uniform Requirements for Manuscripts Submitted to Biomedical Journals,* published in *Am Rev Respir Dis* 1979; 119:3–10; *Ann Intern Med* 1979; 90:95–9; *Br Med J* 1979; 1:532–5; and *Lancet* 1979:1:428–30.
- Cite in numerical order every reference, figure and table. (Order of mention in text determines the number given to each.)
- Place acknowledgments at end of text, before references.

THE REFERENCES

- Type in duplicate; double-space.
- Number the references in order in which they are mentioned in text.
- Provide concluding page numbers for all journal references and specific page numbers for all book references. Indicate all abstracts by the abbreviation (abstr).
- Follow the general arrangement, abbreviations and punctuation styles shown below.

THE FIGURE LEGENDS

- Start at top of new page.
- Type in duplicate; double-space.
- Identify at the end of each legend and in alphabetical order all abbreviations in the figure described.

THE TABLES

- Start each table at top of new page.
- Type in duplicate; double-space.
- Give each table a number (in roman numerals: Table I, II, etc) and a title. Number the tables in order in which they are mentioned in the text.
- Provide a footnote to each table—identifying in alphabetical order all abbreviations used.

THE FIGURES

- Submit 2 glossy prints (not originals) of each photo and drawing.
- Please note that art work of published articles will not be returned.
- Use black ink for all charts (line drawings) Make decimals, broken lines, etc. strong enough for reproduction.
- Use arrows to designate special features.
- Crop photomicrographs to show only essential field.
- Identify figures on back by number and author's name.
- Number figures in order in which they are mentioned in the text.
- Indicate top of each figure.
- Submit written permission from publisher and author to reproduce any previously published figures.
- Limit figures to number necessary for clarity. The publisher allows a limited sum toward reproduction.

Examples of Styles of References

For periodicals, follow INDEX MEDICUS, listing *all* authors (if there are 7 or more, list only 3 and add et al.):

31. Vismara LA, Vera Z, Miller RR, Mason DT. Efficacy of disopyramide phosphate in the treatment of refractory ventricular tachycardia. Am J Cardiol 1977; 39:1027–34.

(Author: please note that no periods are used after authors initials)

For chapter in book:

28. Schiebler GL, Van Mierop LHS, Krovetz LJ. Diseases of the tricuspid valve. In: Moss AJ, Adams F, eds. Heart Disease in Infants. Children and Adolescents. Baltimore: Williams & Wilkins, 1968:134–9.

For books (personal author or authors):

36. Berne E. Principles of Group Treatment. New York: Oxford University Press, 1966:26.

(Author: all book references should have specific page numbers.)

HOW TO MAKE STRESS TESTING A ONE-PERSON OPERATION.

HIRE ANTHRO-METRICS CC-101

Introducing the stress test system that only takes one person to operate: Anthro-metrics CC-101.

Now stress tests can be administered by the doctor. Or by a technician. Either way, the CC-101 delivers improved data accuracy and lower cost per patient than ever before possible.

Printed Test Reports

With the CC-101, there's no time lost taking notes. Or typing them. Because at the end of the test, it automatically summarizes test data for the doctor to review. A printed report provides a complete analysis for the patient's file in a standard 8½" x 11" format.

Improved Accuracy

The CC-101 virtually eliminates artifacts and outside electrical interference. There is automatic time correlation between blood pressure readings, heart rate, S-T segment and test stage. And the CC-101's advanced microprocessor control sets industry standards for accuracy.

Lower Cost per Patient

Anthro-metrics provides physicians with more useful data for less. Less training time. Less time set the machine before tests. Less personnel to conduct the tests. Even less expensive supply costs

So you get more tests. For les cost per patient.

Put ANTHRO-METRICS CC-101 to work for you.

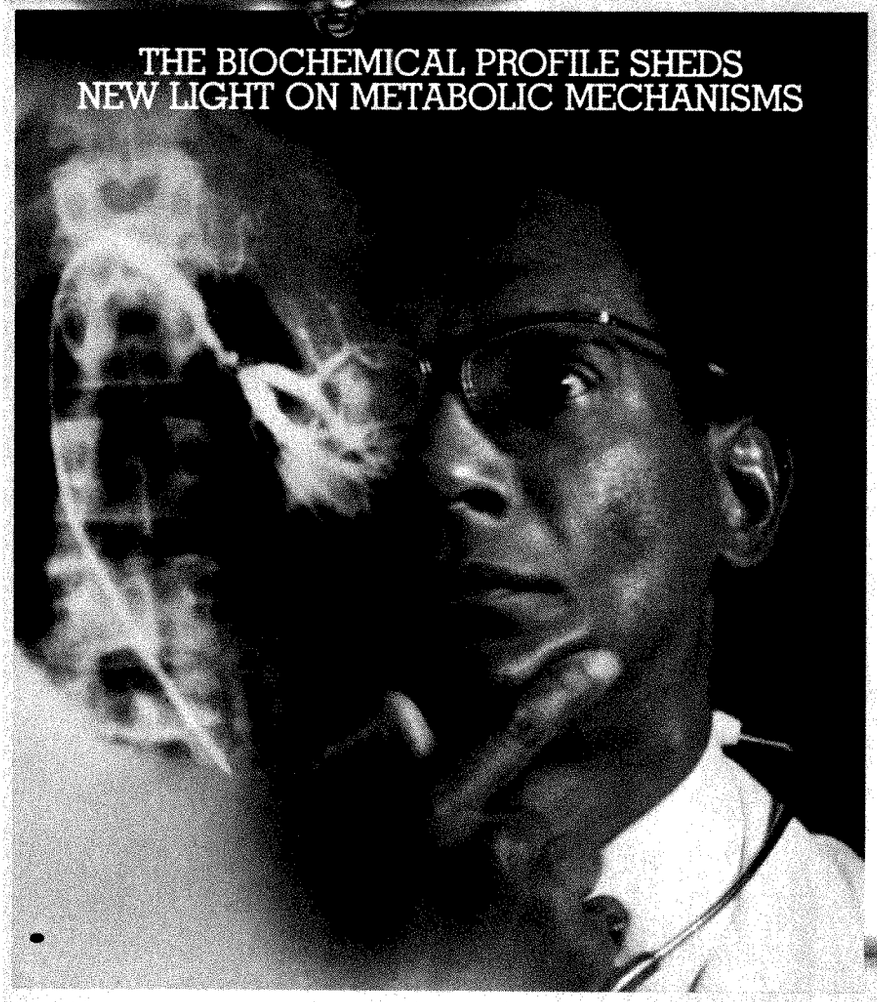
"PROFILING" TODAY'S HYPERTENSIVE PATIENT



THE BIOCHEMICAL PROFILE SHEDS NEW LIGHT ON METABOLIC MECHANISMS

While hypertension still remains an enigma, its metabolic pathways have become clearer in the past twenty years. One of the most important pathways involves the renin-angiotensin-aldosterone system. The kidney is known to secrete renin under three circumstances: 1) when the organ itself becomes ischemic; 2) when the body's sodium content is depressed; 3) when blood volume is reduced. Renin then catalyzes the conversion of the decapeptide angiotensin I to the octapeptide angiotensin II. Besides being the most potent vasopressor known,[1] angiotensin II also stimulates the adrenal gland to produce aldosterone. By enhancing renal reabsorption of sodium, aldosterone expands the body's sodium content and plasma volume. This reduces renin production and closes the loops of the negative feedback system. A breakdown in this system may result in higher levels of renin and angiotensin II—and sustained high blood pressure.

Disturbances in other mechanisms can also trigger metabolic chains of events that lead to hypertension. This increasing knowledge has generated interest in drugs designed to halt the hypertensive process at several points. One of the newest drugs is thought to inhibit the enzyme that converts angiotensin I into angiotensin II.[1] Equally important has been the development of more accurate diagnostic tests for "biochemical" profiling.

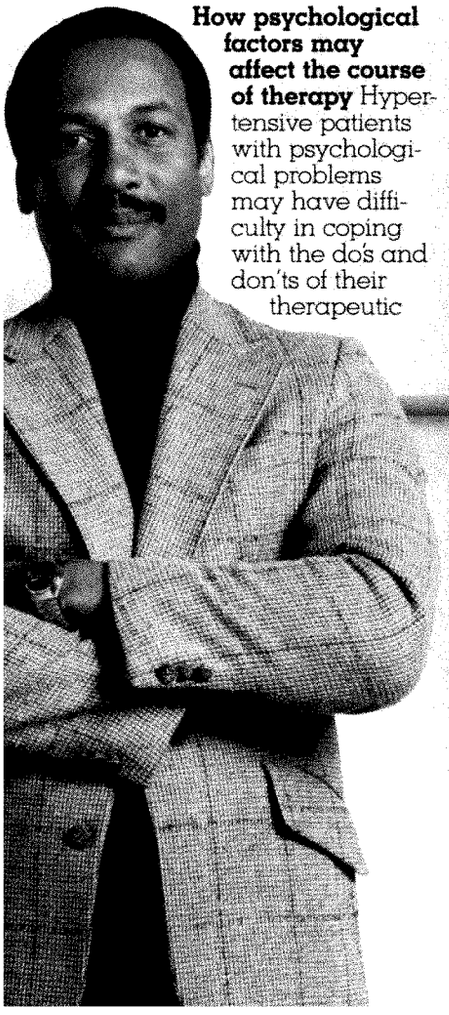
How useful is measuring renin activity? Some clinicians now advocate "renin profiling" of all hypertensives. This rather complicated test provides the renin-sodium index by indirectly measuring the renin level and comparing it to sodium intake. The index helps distinguish renin-dependent hypertensives (about 70% of patients) from those who are sodium-dependent. It is only the latter who are most likely to benefit from diuretics and the "stepped-care" approach.

While renin profiling can be very useful for selected patients, most physicians consider it unnecessary or impractical for routine evaluation. The initial choice of therapy rarely hinges on renin activity.[2] Also, the renin-sodium index is hard to obtain in non-hospitalized patients and may not offer any real advantages over a therapeutic trial that includes a diuretic (for low-renin patients) or a beta blocker (for high-renin patients).[2,3]

The lab workup that works for most patients Some authorities believe that a minimal workup is sufficient for roughly 90% of hypertensive patients.[3] This generally includes a hematologic profile, urinalysis, blood chemistry (covering a number of biochemical variables), along with the standard ECG and chest roentgenogram.[2,3] More exhaustive tests—including renal profiling, intravenous urograms and catecholamine level determinations—would only be ordered if secondary causes are suspected.

THE "PSYCHOLOGICAL PROFILE" ADDS VALUABLE INSIGHTS

At times, it reveals excessive anxiety A good deal of research has focused on the contributory role of psychological and social factors in the development of hypertension. Such factors have been found to increase plasma renin activity.[4] Consequently it is often recommended that some form of psychosocial profile be added to the patient's family and medical history.[2,5] Even though the hypertensive patient may seem calm, a few carefully worded questions often uncover intense psychic tension. The patient's anxiety may center on his psychological problems alone or may extend to the economic and social repercussions of his illness.



How psychological factors may affect the course of therapy Hypertensive patients with psychological problems may have difficulty in coping with the do's and don'ts of their therapeutic program . . . and with demoralizing new self-images as "chronically sick, potentially dependent" persons. The psychological profile helps the physician assess the patient's understanding of his illness, his emotional reactions to it, and the likelihood of his compliance with recommended therapy. This information can help set the stage for the mutually rewarding doctor-patient rapport essential to successful long-term management of any chronic illness.

Why Valium®(diazepam/Roche) can be valuable adjunctive therapy In many cases, your reassurance and continued support will be enough to relieve your patient's emotional distress. But for some patients, you may find that specific antianxiety medication is also warranted. It is at these times that Valium can be especially helpful. Valium works promptly and predictably to relieve the excessive psychic tension that often accompanies organic illness. Initial calming typically occurs within hours—more sustained and extensive symptomatic relief becomes manifest in a matter of days. With intense anxiety under control, the hypertensive patient is often better able to face his condition and to comply with your treatment program. Another important factor—Valium (diazepam/Roche) is used with most primary medications, including cardiac glycosides, diuretics and vasodilators.

Side effects more serious than drowsiness, fatigue and ataxia are rare and seldom severe. As with all CNS-acting agents, patients should be cautioned against drinking alcoholic beverages or driving. Periodic reassessment of the continued need for psychotropic medication is also recommended. Once the patient is again able to cope, Valium should be gradually discontinued. See guidelines on following page for further ways to optimize therapy with Valium.

VALIUM®(IV)
diazepam/Roche
2-mg, 5-mg, 10-mg scored tablets

WHEN ANXIETY DISORDERS HAMPER HIS ABILITY TO COPE

Before prescribing, please see brief summary of product information on following page.

ROCHE

VALIUM®
diazepam/Roche

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Management of anxiety disorders, or short-term relief of symptoms of anxiety; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).
The effectiveness of Valium in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should periodically reassess the usefulness of the drug for the individual patient.
Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.
Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms similar to those with barbiturates and alcohol have been observed with abrupt discontinuation, usually limited to extended use and excessive doses. Infrequently, milder withdrawal symptoms have been reported following abrupt discontinuation of benzodiazepines after continuous use, generally at higher therapeutic levels, for at least several months. After extended therapy, gradually taper dosage. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.
Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.
Dosage: Individualize for maximum beneficial effect. *Adults:* Anxiety disorders, symptoms of anxiety, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).
Supplied: Valium® (diazepam/Roche) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available in trays of 10.

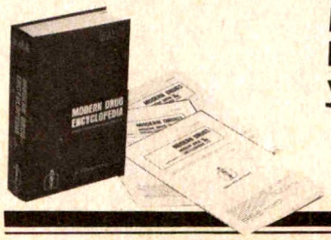
is your drug reference?



If it's not MODERN DRUG ENCYCLOPEDIA, you can't be sure.

MODERN DRUG ENCYCLOPEDIA and Therapeutic Index 15th Edition
Arthur J. Lewis, MD, Executive Editor
Gertrude Dittus Gonzales, R.Ph., B.S. Pharm., Executive Editor
Charles L. Winek, Ph.D., Contributing Editor

The all new 15th Edition of MODERN DRUG ENCYCLOPEDIA is written especially for the practitioner who needs complete, objective information on prescription drugs.

An independent team of pharmacists and physicians has researched and edited all the facts on 3,000 prescription drugs. It passes this research on to you in an easy to absorb style that's perfectly suited to the tight schedule of a time pressed practitioner.

Some handbooks just reprint manufacturers' package inserts. They don't edit. Just print material manufacturer pays to have included.

Here's what careful planning does for MODERN DRUG ENCYCLOPEDIA:
- limits entries to prescription drugs. You don't waste time flipping through pages of extraneous drugs.
- lists over 3,000 pharmaceuticals, biologicals, and allergens in one a-z sequence.
- arranges entries by generic name. All brand names in one place.
- written in concise language for quick comprehension
- designed with a "strong focus" layout, easy-to-read type, and bold subject headings.

The 1,000 page main section arranges over 3,000 drugs alphabetically by generic name. Each entry covers vital facts about brand names and each manufacturer that markets their own brand.

Three a-z indexes provide instant access to all the material found in the main secton as follows:
- GENERAL INDEX of all brand generic names in handy alphabetic sequence.
- THERAPEUTIC INDEX of which drugs are prescribed for which purpose. Allows you a wide selection of therapy based on your patient's special needs.
- MANUFACTURERS INDEX of names and addresses and product names. Helps you identify the drug when you only know the manufacturer's name.

And, our Free Updating Service informs you of changes in specifications and introduces new drugs. These periodic supplements adopt the same easy-to-read format of the basic volume. You receive them free of charge until the publication of the next (16th) Edition.

Try using MODERN DRUG ENCYCLOPEDIA for 30 days at our risk. Then keep it only if you're convinced that it answers a practitioner's need for concise, easy to read information on prescription drugs.

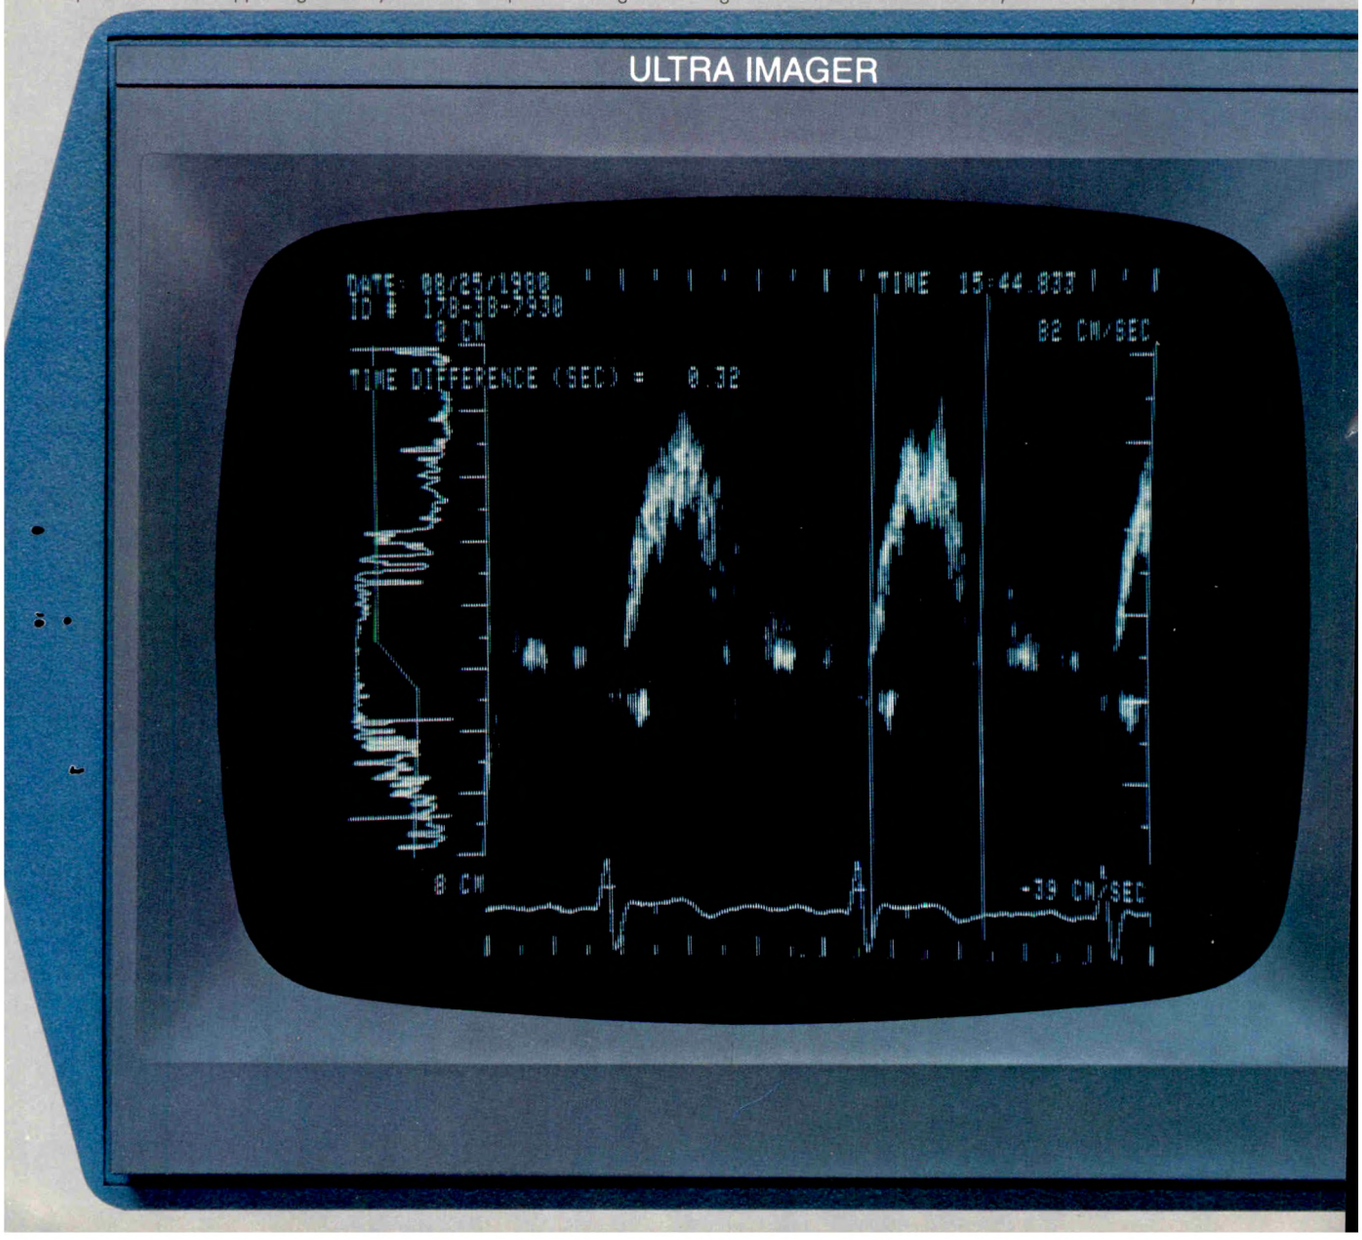
E for M/Honeywell announces the first major advance of the 1980's in echocardiography...

Ultra Imager

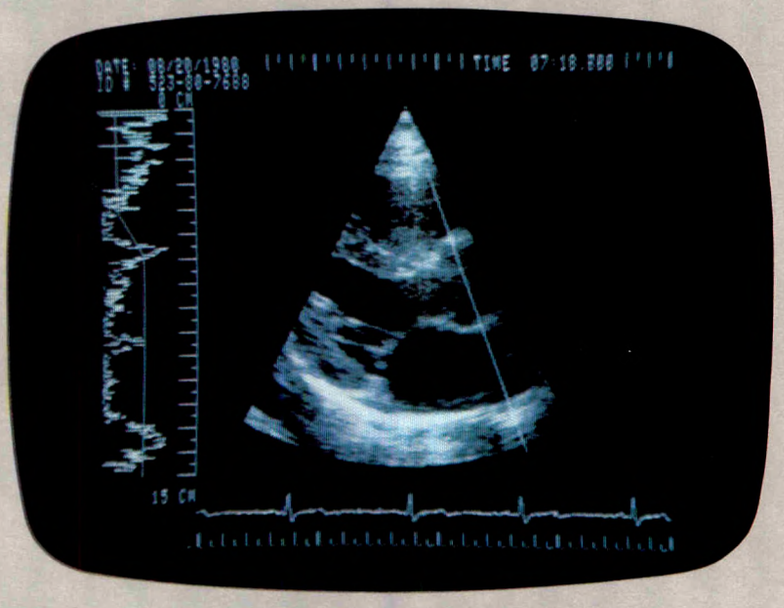
The only integrated digital echocardiography system with all <u>three</u> major modalities for complete ultrasound diagnosis:

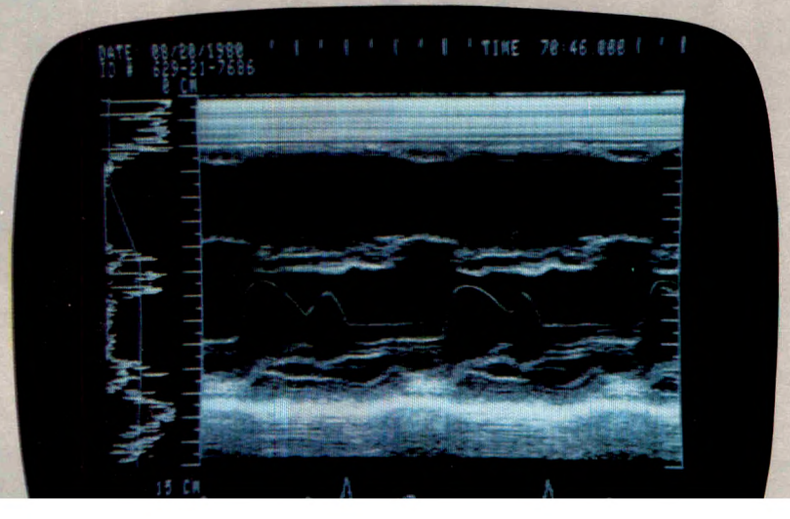
- **FFT Doppler**
- **2D Real-time**
- **M-mode**

This pulsed Doppler display is a precise, quantitative representation of a spectrum of blood velocities in the pulmonary artery. The Ultra Imager's unique method of Doppler signal analysis ensures repeatable diagnostic images never before available in any clinical ultrasound system.



E FOR M / Honeywell





Three complementary imaging modalities:

- Pulsed Doppler
- Real-time
- M-mode

On a single video display, the Ultra Imager presents enhanced 2D sector scans, M-mode images or pulsed Doppler data. These three imaging modalities are combined in ways that yield more diagnostic information than ever before. For example, you can change instantly from one mode to another by pressing a button—or use a cursor on a 2D image to determine the placement of an M-mode recording.

The Ultra Imager's multiprocessor system puts cursors and image controls at your fingertips. It also places graphics and alphanumeric messages on the screen to make every examination faster and easier.

The Ultra Imager also provides diagnostic quality physiological signal conditioning. Every system includes an ECG channel and can accommodate optional pulse/phono and respiration channels.

Cost-effectiveness built into the Ultra Imager System

The Ultra Imager offers many cost-effective features that enhance its value to cardiology practice. The mechanical sector scan was selected for the system because it offers superior performance in 2D/Doppler imaging at lower cost. In addition, it will permit ready adaptation to future transducer technologies.

Ease of maintenance is again achieved, along with greater electronic stability, by comprehensive digital processing throughout the system. Integrated design of the Ultra Imager avoids the cabling connections and duplicated components associated with the "stacked box" approach.

The system's digital scan converter (image memory) provides you with non-fade displays and gives you instantaneous freeze-frames in any mode without flickering or fading. These advanced display capabilities facilitate diagnostic review and the measurement and recording of scan data.

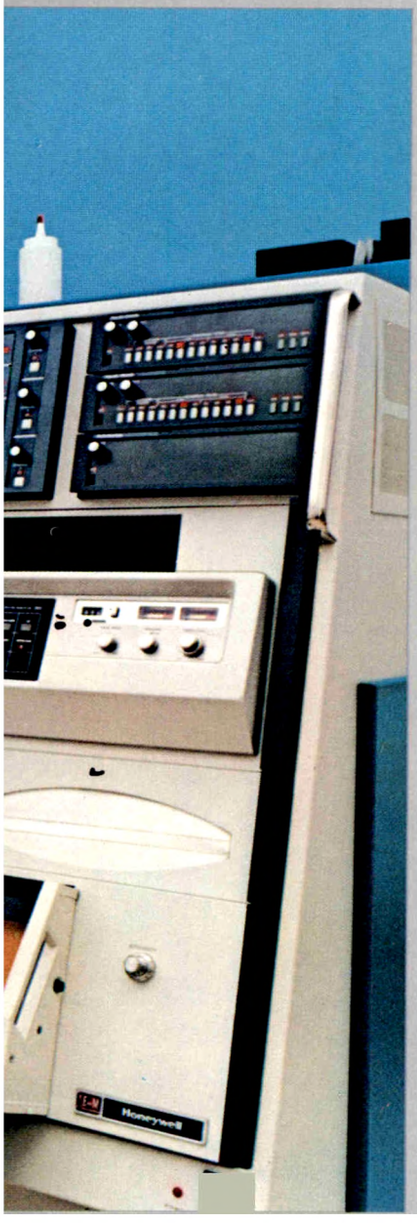
The unique Auto-Test feature of the Ultra Imager allows the system to test itself for failures. If a failure exists, an appropriate indicator light signals the source of the failure. This simplifies servicing of the instrument.

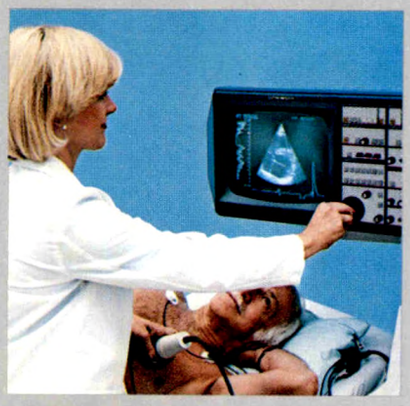
Human engineered with unique operator convenience features

Through careful attention to human engineering details, we have made a sophisticated imaging system easy to operate. For instance, both the monitor and primary control panel are on a movable gantry that can be positioned near the patient for ease of use and viewing. This makes system controls conveniently accessible to the operator while at the patient's bedside.

The Ultra Imager also includes an audiovisual self-teaching feature which employs the system's videotape recorder to play training programs produced by E for M/Honeywell. This convenient feature makes staff training a much simpler procedure.

For operator convenience, all displays can be viewed easily even in a daylit room. There is also built-in storage space for gels, tissues, paper and other supplies. Because the cart is compact and easily maneuvered, it can be moved wherever needed.





Operator can position the transducer and be within convenient reach of all necessary scan controls.

Cardiologist can perform off-line data analysis while listening to voice annotations recorded by the operator.

Audiovisual self-teaching feature facilitates training of new personnel.

A versatile imaging system that offers more diagnostic information and greater clinical utility.

Today the key to diagnostic value in an echocardiography system is the availability of accurate and repeatable pulsed Doppler images. The Ultra Imager offers you this plus the complementary imaging capabilities you need to perform cardiac examinations.

Using a sophisticated spectral analysis technique called Fast Fourier Transform (FFT) the Ultra Imager can process Doppler blood velocity data in real time without the need for an operator to calibrate gain and threshold settings. This makes quantitation of blood flow patterns and flow rates throughout the heart a much simpler clinical procedure.

The Ultra Imager's built-in versatility is made possible by a unique, dedicated array processor designed to handle the high-speed computations required for repeatable Doppler imaging. The computing power of this separate processor makes it possible to combine accurate blood velocities with 2D imaging data to provide the essential measurements for determining stroke volume and cardiac output. The Ultra Imager is the only 2D/Doppler System available offering this level of diagnostic versatility.

Honeywell's new LS-8 recorder is a standard system feature. It allows you to make a hard copy of the display with full gray scale reproduction and high resolution. You can select page print or strip chart modes and get crisp, black-on-white records with immediate dry processing.

High quality videotaped images are formatted to allow off-line data analysis on playback images. This storage feature allows both physician and operator to conduct diagnostic reviews when it is most convenient.

The E for M/Honeywell Commitment

E for M/Honeywell has a special commitment to cardiology. Because we've worked with you for over 30 years, we know the kind of service and performance you demand from a medical instrument company. Over the years, we've developed a professional rapport which has led to the development and manufacture of many of the best-engineered, high performance instruments in the healthcare field. The Ultra Imager is one more example of this continuing commitment to excellence.

Service

The Ultra Imager is supported in the field by our own specially trained ultrasound service technicians. Because there are over 40 service locations in the U.S. alone, E for M/Honeywell service is fast and responsive. A toll-free number connected to the Ultra Imager Support Center makes service available 24 hours a day.

The Ultra Imager's Auto-Test feature further minimizes downtime by pinpointing any failures in the system. Now if a service call is needed the technician knows which parts are required to repair the system on-site. In addition, the Repair/Exchange program provides immediate replacement parts for your service technician with the lowest possible board repair cost through the use of Automatic Test Equipment at the factory.

Quality Assurance

The Ultra Imager was designed with reliability and ease of maintenance in mind. "MIL-Spec" reliability analyses were used to evaluate every aspect of the system design. Each subassembly has been thoroughly tested individually and as part of the complete system. And every completed unit is subjected to rigorous temperature cycling so that any marginal components can be replaced in the factory. This means that the system we install for you is in optimum working order.

Clinicopathologic Correlates of Acute Ischemic Heart Disease Syndromes

L. MAXIMILIAN BUJA, MD, FACC
JAMES T. WILLERSON, MD, FACC

Dallas, Texas

To better define the relations among acute and chronic coronary arterial lesions and different syndromes of acute ischemic heart disease, the clinicopathologic findings in 100 recent myocardial infarcts in 83 patients were reviewed and the results correlated with those of previous studies. Severe atherosclerosis (greater than 75 percent narrowing of luminal cross-sectional area) involved three or more major coronary arteries in 65 percent; two arteries in 16 percent, one artery in 15 percent, and no arteries in 4 percent of cases. The incidence rate of recent occlusive coronary arterial lesions was 61 percent, including 50 (90.2 percent) of 55 grossly apparent transmural infarcts, 9 (34.6 percent) of 26 grossly evident subendocardial infarcts and 2 (10.5 percent) of 19 multifocal microinfarcts associated with clinical episodes of acute coronary insufficiency ($p < 0.001$). The 61 recent occlusive lesions consisted of two thromboemboli, two isolated plaque hemorrhages and 57 in situ thrombi that were associated with a high incidence rate of plaque erosion, rupture and hemorrhage. Clinical conditions predisposing to reduced coronary perfusion were identified before the onset of 26.2 percent of infarcts with recent occlusions and 61.5 percent of infarcts without recent occlusions ($p < 0.001$). Clinical onset of infarction was followed by severe cardiac pump failure or congestive heart failure in 63.9 percent of infarcts with and 41.0 percent of infarcts without recent occlusions ($p = 0.04$).

From this and previous studies, it is concluded that (1) acute ischemic heart disease does not have a constant relation with the severity of chronic atherosclerosis; (2) myocardial necrosis commonly occurs in the absence of acute permanent coronary occlusion, but in this setting is usually limited to subendocardial involvement of variable extent; (3) acute coronary thrombosis frequently acts as a major factor in determining the extent and distribution of an evolving infarct, as indicated by the large incidence of occlusive coronary thrombi with regional transmural infarcts; and (4) coronary thrombus formation is not dependent on a generalized impairment of coronary perfusion, either before or after the onset of infarction.

From the Departments of Pathology and Internal Medicine (Cardiac Unit), Southwestern Medical School, The University of Texas Health Science Center at Dallas, Dallas, Texas. This study was supported in part by Ischemic Heart Disease (SCOR) Grant HL-17669 from the National Institutes of Health, Bethesda, Maryland. Manuscript received June 30, 1980; revised manuscript received September 2, 1980, accepted September 9, 1980.

Address for reprints: L. Maximilian Buja, MD, The University of Texas Health Science Center at Dallas, Department of Pathology, 5323 Harry Hines Boulevard, Dallas, Texas 75235.

Numerous clinicopathologic studies of patients with fatal ischemic heart disease have previously been reported in an attempt to define the pathogenesis of the clinical syndromes.[1–29] However, controversy remains regarding the frequency and significance of severe atherosclerosis, acute coronary thrombi and other acute coronary lesions in patients with acute myocardial infarction and other ischemic heart disease syndromes. A new dimension to this issue has been added with evidence that coronary arterial spasm may act as a pathophysiologic factor in patients with typical and atypical angina pectoris and acute myocardial infarction.[29–36] This study was undertaken to document pertinent findings in a group of hospitalized patients with autopsy evidence of ischemic heart disease

and recent myocardial necrosis, including patients with a clinical diagnosis of acute myocardial infarction and patients with unstable angina pectoris or other forms of acute coronary insufficiency.[37]

Two important features of the study were that (1) all myocardial infarcts occurring within 3 months of death were included whether or not death directly resulted from the infarct, and (2) each pathologic lesion was correlated with clinical findings occurring before and after the clinical onset of infarction. The study was limited to myocardial lesions occurring within 3 months of death because morphologic methods can be used to estimate the age of myocardial and coronary lesions occurring within this time interval on the basis of recognition of stages in the organization and healing process.[15,25,38–40] The goals of this study were: (1) to define more clearly the roles of coronary atherosclerosis and acute coronary lesions, including thrombosis, in the development of clinical coronary insufficiency and acute myocardial infarction; (2) to correlate the findings with those of previous clinicopathologic studies; and (3) to obtain thereby a broader perspective concerning the clinicopathologic features of acute ischemic heart disease.

Methods

Patients studied: The study group was derived from patients who came to autopsy over a 5 1/2 year period (1974 to 1979) at Parkland Memorial Hospital or the Veterans Administration Hospital in Dallas, Texas. The study was limited to 83 patients whose heart was examined for research purposes in a detailed and systematic fashion at the time of autopsy. The autopsy and clinical findings were subsequently reviewed when the data presented herein were compiled.

Two groups of patients were included in the study: (1) 71 patients with autopsy evidence of one or more discrete, usually grossly obvious, recent myocardial infarcts, with or without a definite clinical diagnosis of myocardial infarction, and (2) 19 patients, including 7 from the first group, with autopsy evidence of recent multifocal myocardial necrosis, confirmed histologically, and a clinical history compatible with some type of acute coronary insufficiency syndrome including unstable angina pectoris or recurrent severe angina pectoris. Patients in the category of sudden death without demonstrable myocardial necrosis were not included in this study because of the nature of the patient group and the criteria for inclusion in the study.

An event (myocardial infarction or coronary insufficiency) was defined as recent if autopsy and clinical evidence indicated an occurrence within 3 months of death. The study was limited to myocardial infarcts that developed spontaneously and did not include myocardial infarcts that developed as a possible sequela of cardiac surgery or other diagnostic or therapeutic procedures.

A clinical diagnosis of acute myocardial infarction was based on standard criteria including a history of prolonged chest pain, a clearly abnormal evolutionary pattern of serum enzyme tests including increased serum creatine kinase (CK) and, more recently, increased CK-MB or CK-B isoenzymes, as well as diagnostic or compatible electrocardiographic changes or a positive technetium-99m stannous pyrophosphate myocardial scintigram, or both. A clinical diagnosis of acute coronary insufficiency was made when clinical symptoms were suggestive of episodes of prolonged myocardial ischemia but a definitive diagnosis of acute myocardial infarction was not made. Most patients in the group with acute coronary insufficiency had the diagnosis of unstable angina pectoris, which was defined as severe, recurrent and progressive chest pain that was of recent onset or represented a change in pattern in a patient with previously stable angina.[37] Other acute coronary insufficiency syndromes were diagnosed clinically as recurrent severe angina pectoris and recurrent acute pulmonary edema.

Autopsy studies: The hearts were initially examined in the fresh state but, in some cases, after fixation in a phosphate-buffered solution of 10 percent formalin. Postmortem coronary angiographic procedures were rarely performed. The major coronary arteries were dissected by making multiple transverse cuts at 3 to 5 mm intervals. If the coronary arteries were heavily calcified, fixation and decalcification were performed before extensive coronary dissection was undertaken. This was accomplished either by removal of major coronary segments from the hearts before processing or by incubation of the entire heart in a decalcification solution before the coronary arteries were sectioned in situ.

After gross examination of the coronary arteries, coronary lesions were marked on a standard diagram. For each coronary artery (left main, left anterior descending, left diagonal or marginal (or both), left circumflex and right coronary artery), the extent and severity of coronary artery disease was noted. An estimate was made of the percent narrowing of the luminal cross-sectional area produced by the lesion, taking into account postmortem collapse of the vessels. Selected areas of the coronary arteries were processed for histologic examination, including all occlusive lesions, lesions representing sites of maximal luminal narrowing for all coronary arteries, and representing areas distal to sites of maximal narrowing. Blocks containing occlusive lesions were frequently step-sectioned, but serial sectioning was not performed. Histologic examination was used to evaluate the nature of the coronary arterial lesions as well as to confirm the gross impression regarding percent luminal narrowing.

The heart was opened in most cases by cutting the ventricles into several transverse slices ("breadloafing technique"). Heart weight was determined and evidence of chamber hypertrophy and dilatation and focal lesions were noted. The location and relative size of all grossly visible myocardial infarcts were recorded. Histologic sections of myocardium were prepared and examined in each case. The age of each myocardial infarct was estimated using standard gross and histologic criteria.[25,26,38–40] An infarct was designated transmural if the infarct exhibited prominent involvement of the outer as well as the inner half of the left ventricular wall and subendocardial if it was essentially confined to the inner half of the left ventricular wall. In addition to discrete myocardial infarcts, evidence was recorded of multifocal small foci of myocardial necrosis or fibrosis. These lesions were often detectable only microscopically, but were occasionally extensive enough to be grossly visible. Recent multifocal microinfarcts in the patients with evidence of acute coronary insufficiency consisted of foci of acute or organizing necrosis or myocytolysis, or both.[25,26,38–40]

Statistical analysis: Standard chi-square analysis was used to test for differences in the incidence of coronary arterial lesions between different types of myocardial infarcts (Table I) and between infarcts of different ages (Table II). Chi-square analysis was also used to test for differences in the incidence of various autopsy and clinical findings between infarcts with

and without associated acute coronary occlusive lesions (Tables III to V).

Results

Autopsy Findings

Myocardial infarcts: At autopsy, 81 discrete, usually grossly obvious, recent myocardial infarcts and 19 multifocal microinfarcts were identified (Tables I to III). Of the 100 myocardial infarcts, 67 had clinicopathologic features consistent with an age of 12 hours to 20 days and 33 had features consistent with an age of 3 weeks to 3 months. Each of the 81 gross myocardial infarcts had a discrete focus of coagulation necrosis or of granulation and fibrous tissue consistent with previous coagulation necrosis. Of the 81 gross myocardial infarcts, 55 were transmural and 26 were subendocardial. Of the 55 transmural infarcts, 27 were anterior, 23 inferoposterior, and 5 both anterior and posterior. Of the 26 subendocardial infarcts, 8 were anterior and 10 inferoposterior; 8 exhibited anterior as well as posterior or circumferential involvement. On histologic examination, the 19 multifocal microinfarcts were predominantly located in the subendocardium and consisted of variable combinations of coagulation necrosis, myocytolysis, granulation tissue and fibrosis (Fig. 1).

Associated coronary arterial lesions: The myocardial infarcts were associated with coronary atherosclerosis of variable extent and severity and occurred with and without demonstrable recent coronary arterial lesions. Of the 100 myocardial infarcts, 61 were associated with recent coronary occlusive lesions, 4 were associated with small nonocclusive mural thrombi and 35

* One patient died after coronary arterial bypass surgery performed after the clinical onset of infarction and pump failure. † Cardiac operations consisted of ventricular aneurysm resections in 2 cases, coronary arterial bypass surgery in 1 and aortic valve replacement in 1 case. ‡ Death resulted from cardiac pump failure or arrhythmias, or both, and occurred within 1 to 2 days of operation in 15 cases and after 10 days in 1 case.
CABG = coronary arterial bypass graft; CHF = congestive heart failure; Occl = recent coronary arterial occlusion.

occurred without a demonstrable recent coronary lesion (Table I). The occlusive nature of the lesions was originally evaluated on gross examination. On subsequent light microscopic examination, the occlusive lesions generally showed 100 percent stenosis, although some were associated with very small lumens, which could be accounted for by real or artifactual retraction of thrombus or by recanalization of older thrombi. The 61 occlusive lesions consisted of 2 thromboemboli (defined by previously described criteria),[10] 2 plaque hemorrhages and 57 in situ thrombi (Fig. 2 to 4). Two of the recent occlusive thrombi occurred in atheromatous saphenous vein bypass grafts implanted, respectively, 4 and 6 years previously; the other occlusive lesions occurred in the native coronary arterial circulation.

Recent coronary occlusive lesions: Recent coronary occlusive lesions were associated with 90.2 percent of gross transmural infarcts, 34.6 percent of gross subendocardial infarcts and 10.5 percent of multifocal microinfarcts ($p < 0.001$) (Table I). The interval between occurrence of infarction and death did not have an influence on the detection of coronary occlusive lesions (Table II). Coronary occlusions were detected in association with 61.2 percent of infarcts 12 hours to 20 days old and 60.6 percent of infarcts 3 weeks to 3 months old. The recent myocardial and coronary lesions exhibited generally similar histologic ages, but no attempt was made to determine precisely the relative ages of infarcts and coronary lesions using histologic criteria. The age of the infarct did influence the detection of lesions associated with coronary thrombi because 67.6 percent of coronary thrombi associated with prominent plaque hemorrhage as well as erosion or rupture, or both, occurred with infarcts 12 hours to 20 days old; whereas only 20 percent of thrombi associated with such changes occurred with infarcts 3 weeks to 3 months old ($p = 0.002$). The overall incidence rate of plaque lesions with thrombi was 50.9 percent. Plaque erosion was identified as thinning, degeneration and loss of structural integrity of the fibrous capsule of an atheromatous plaque (Fig 2 and 3), and plaque rupture as a prominent complete break and separation of the capsule (Fig. 4). Plaque disruption was associated with prominent intraplaque hemorrhage and, in some cases, with atheromatous material (foam cells and cholesterol clefts) in the overlying thrombus or lumen of the distal vessel (Fig. 4).

Each of the recent coronary lesions was associated with a single myocardial infarct and, conversely, only one recent coronary lesion was associated with a given infarct. Of the 65 recent occlusive and nonocclusive lesions, 12.3 percent occurred in vessels with minimal to moderate old atherosclerosis and 87.7 percent in vessels with at least focally severe atherosclerosis (Table I). Atherosclerotic narrowing was severe (greater than 75 percent reduction in luminal area) at the site of the recent lesion in 81.5 percent of cases, but severe narrowing of the artery distal to the recent lesion occurred in only 63.1 percent. The recent coronary lesions were generally located in the vessels that supplied the infarcted region. In the seven cases of recent coronary

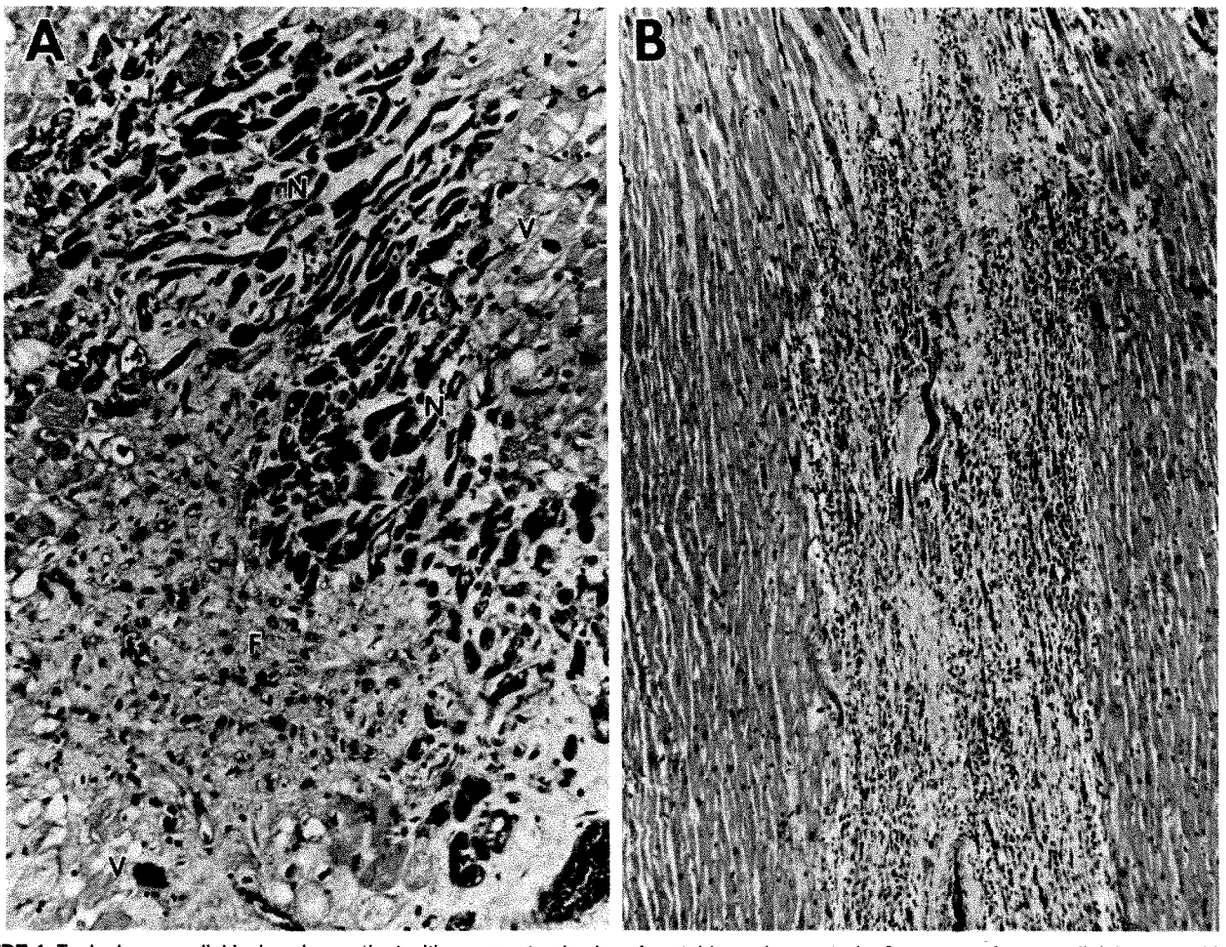

FIGURE 1. Typical myocardial lesions in a patient with recurrent episodes of unstable angina pectoris. **A,** an area of myocardial damage with foci of acute coagulation necrosis (N), early replacement fibrosis (F) and vacuolated muscle cells (V) with hydropic and myocytolytic degeneration. **B,** subacute lesion composed of granulation tissue with a few unresorbed necrotic muscle cells. (Hematoxylin-eosin ×140.)

lesions and multiregional or circumferential myocardial infarcts, the recent coronary lesions were associated with extensive severe multivessel coronary atherosclerosis, usually with one or more old occlusions. Severe and extensive coronary atherosclerosis also was present in one case in association with an acute inferior myocardial infarct and an acute occlusive thrombus of the left anterior descending coronary artery ("paradoxical infarction").

Chronic myocardial changes: Chronic cardiac alterations associated with gross transmural infarcts, gross subendocardial infarcts and multifocal microinfarcts, with and without recent coronary occlusions, are presented in Table III. Cardiac hypertrophy (heart weight greater than 400 g) was present with 85 percent of the recent myocardial infarcts, including 86.9 percent of infarcts with recent coronary occlusions and 82.1 percent of infarcts without recent occlusions. A previous myocardial infarct or patchy fibrosis, or both, occurred before 70 percent of the recent infarcts, including 60.7 percent of infarcts with and 84.6 percent of infarcts without recent associated occlusions ($p = 0.02$).

Chronic coronary arterial changes: Severe coronary arterial narrowing (greater than 75 percent of luminal area) by old atherosclerotic plaques involved none of the major coronary arteries with 4 recent infarcts, one coronary artery with 15 infarcts, two coronary arteries with 16 infarcts and three to five coronary arteries with 65 infarcts. The incidence of vessel involvement by severe atherosclerosis was similar in cases with and without a recent occlusive lesion. Two cases were associated with significant, extensive and severe intramural coronary artery disease. In one case severe atherosclerosis of the extramural arteries was present and in another the extramural arteries were patent; a recent coronary occlusive lesion was not present in either case. There was a significant difference ($p < 0.001$) in the types of myocardial infarcts in the cases with and in the cases without coronary occlusion; regional anterior and inferoposterior infarcts occurred more frequently in the presence of an acute coronary occlusion, and multiregional gross infarcts and multifocal microinfarcts occurred more frequently in the absence of a recent coronary occlusion.

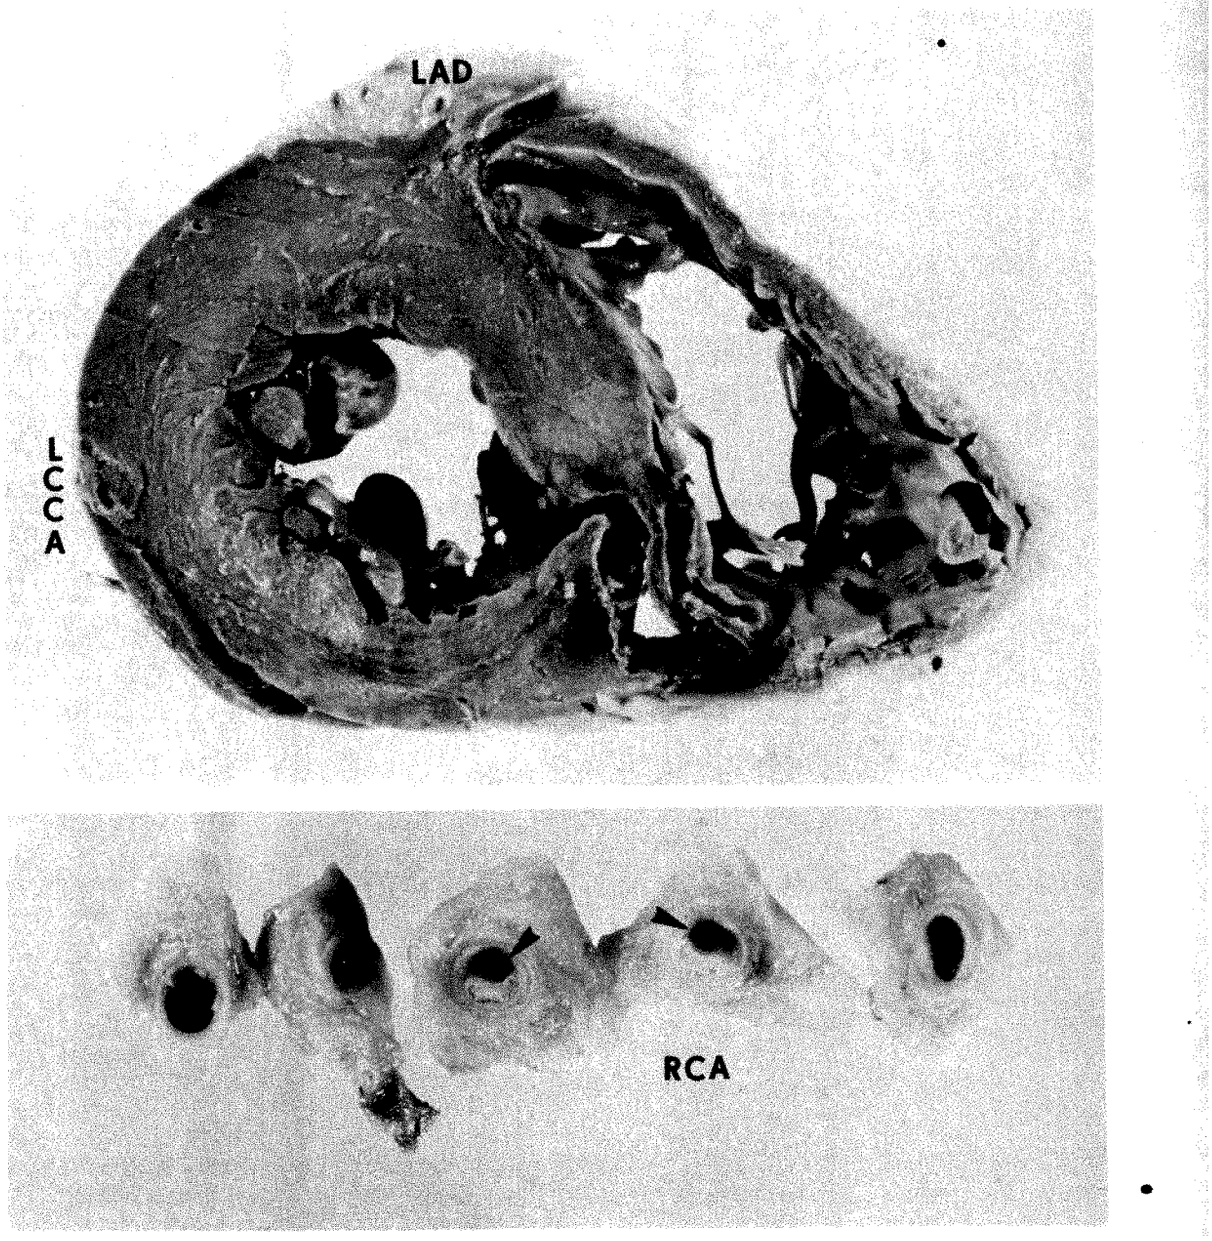

FIGURE 2. Two day old inferoposteroseptal transmural myocardial infarct with ventricular septal rupture in a 51 year old woman. The left anterior descending coronary artery (LAD) shows moderate atherosclerosis and the left circumflex coronary artery (LCCA) is free of disease. At the site of the only severely stenotic plaque in the right coronary artery (RCA), there is an occlusive thrombus adjacent to an area of major plaque hemorrhage. The **arrows** indicate a plane of demarcation formed by a thin strand of attenuated and eroded plaque capsule between the centrally located thrombus and the peripheral plaque hemorrhage (see Fig. 3). Thrombus is also located immediately proximal and distal to the plaque. More distal segments of the artery do not have significant atherosclerosis or thrombus.

Clinical Findings

Clinical diagnosis of myocardial infarction and acute coronary insufficiency: The 100 recent myocardial infarcts occurred in 83 patients. Of the 83 patients, 55 had one, 8 had two and 1 had three gross infarcts; 7 had one gross infarct and a separately identified region of multifocal microinfarction, and 12 had multifocal microinfarcts. Of the 81 gross myocardial infarcts in 71 patients, 70 infarcts (86.4 percent) were associated with a clinical diagnosis of acute myocardial infarction; the remaining 11 lesions (13.6 percent) were not associated with a suspected or established clinical diagnosis of infarction. Eight of the 11 latter lesions were gross subendocardial infarcts. The multifocal microinfarcts occurred in 19 patients who experienced one or more episodes of acute coronary insufficiency within 3 months of death. The clinical diagnoses were unstable angina pectoris in 13 patients, recurrent severe angina

FIGURE 3. Same case. Histopathologic features of the acute right coronary occlusion shown in Figure 2. The coronary plaque shows superficial erosion (E) with disruption of fibrous tissue and hemorrhage in the plaque and thrombus (T) in the lumen. (Hematoxylin-eosin ×144, reduced by 5 percent.)

pectoris in 5 and recurrent painless acute pulmonary edema in 1 patient with diabetes mellitus.

Previous cardiovascular disease and predisposing factors: Clinical cardiovascular alterations occurring before the clinical onset of myocardial infarction are shown in Table IV. A history of prior angina pectoris was noted in 68 percent and a history of documented systemic hypertension in 48 percent. The incidence of these two findings was similar with infarcts with and without associated coronary occlusion. Clinical conditions predisposing to reduced coronary perfusion were diagnosed before the onset of infarction in 40 percent of cases. These alterations consisted of chronic or recurrent congestive heart failure, aortic stenosis and septic or toxic shock. Such alterations were documented before the occurrence of 61.5 percent of infarcts without and only 26.2 percent of infarcts with associated recent occlusions ($p < 0.001$). Among the 39 infarcts without associated recent occlusions, the incidence rate of predisposing hemodynamic alterations was 76.4 percent for gross subendocardial infarcts, 60.0 percent for gross transmural infarcts and 47.1 percent for multifocal microinfarcts. One of the infarcts developing in the absence of a history of a predisposing generalized hemodynamic alteration or a recent coronary occlusive lesion occurred in the only patient in the series with a history of Prinzmetal's variant angina pectoris.

Clinical course: Major features of the clinical course after the clinical onset of myocardial infarction are shown in Table V. Early onset (usually within 24 hours) of progressive and fatal cardiac pump failure occurred in 41 percent of cases, including 29 (47.5 percent) of 61 infarcts with and 12 (30.8 percent) of 39 infarcts without associated recent coronary occlusions ($p = 0.15$). Cardiac pump failure was manifested by hypotension, decreased urinary output and signs of peripheral vasoconstriction with variable degrees of pulmonary congestion. Other syndromes of impaired cardiac output included late onset pump failure and chronic congestive heart failure. The clinical syndromes of cardiac congestive or pump failure were associated with 55 percent of infarcts including 39 (63.9 percent) of 61 infarcts with and 16 (41.0 percent) of 39 without associated recent coronary occlusion ($p = 0.04$). The other 45 infarcts, including 22 of 61 infarcts with and 23 of 39 without associated recent occlusion, were not directly associated with prominent clinical findings of cardiac congestive or pump failure. These 45 infarcts included 15 that were complicated by fatal arrhythmias and 30 that were followed by survival with subsequent death from a new infarct, postoperative acute pump failure or metastatic cancer. All postoperative patients included in this study were judged to have myocardial infarcts that clearly antedated the operative intervention.

Discussion

General Findings

This study has shown that (1) the degree of chronic coronary atherosclerosis does not have a constant relation with the occurrence of acute episodes of ischemic heart disease, although most acute events occur in the setting of significant triple vessel disease; (2) clinical acute coronary insufficiency frequently is associated with multifocal myocardial necrosis in the absence of an acute coronary occlusive lesion; (3) transmural myocardial infarcts are associated with a much greater incidence of acute coronary occlusion than are subendocardial infarcts; (4) acute coronary thrombosis is frequently associated with acute alterations of the arterial wall characterized by plaque erosion, rupture and hemorrhage; and (5) the development of acute coronary thrombosis is not directly dependent on the occurrence of a generalized impairment of coronary perfusion, either before or after the onset of infarction.

A variety of factors involving differences in patient populations, case selection procedures and criteria used for subcategorization of cases undoubtedly influence the incidence of severe coronary atherosclerosis and acute occlusive lesions reported for various categories of ischemic heart disease.[1–28] However, the data indicate that the incidence of recent thrombosis is greatest with regional transmural infarcts, least with multifocal

or circumferential subendocardial infarcts and intermediate with regional subendocardial infarcts.[4,7-11,15,16,20,21,27] Our findings are in accord with previous data indicating a very large incidence of recent coronary thrombosis with regional transmural infarcts.[7,9,11,15,16,20,21] The findings with regard to coronary insufficiency are also in accord with previous data showing frequent occurrence of focal myocardial necrosis and fibrosis with various anginal syndromes.[3,14,17,19,25,26]

A complete picture of acute coronary artery disease also requires consideration of the major category of sudden death. This event typically occurs instantaneously or within minutes to a few hours of onset of

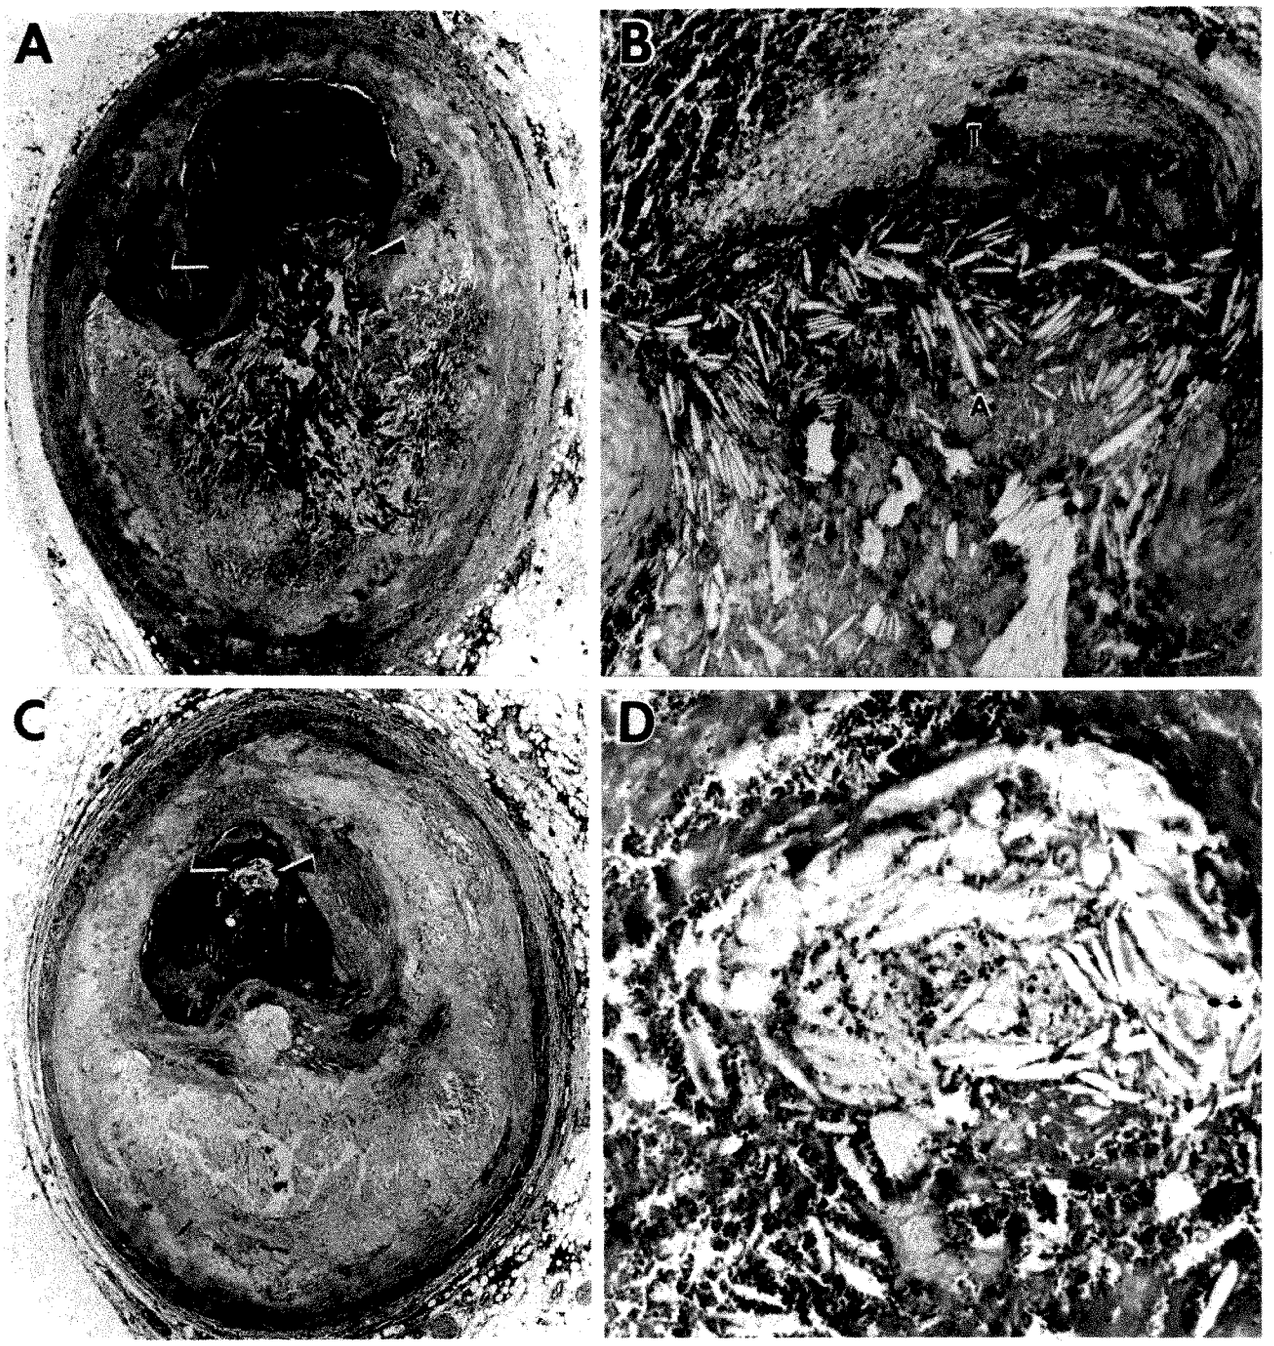

FIGURE 4. Histopathologic features of a coronary occlusion with plaque rupture, hemorrhage and thrombosis. **A,** the ruptured plaque shows separation of the capsule (**arrowheads**), outward displacement of plaque contents across the rupture site and communication with the overlying thrombus. **B,** higher magnification of the site of plaque rupture showing continuity between thrombus (T) and atheromatous (A) material of the plaque core. Note the abundant cholesterol crystals in the atheromatous material. **C,** a more distal segment of the artery shows atheromatous debris within the thrombus (**arrowheads**). **D,** higher magnification view of the atheromatous material within the thrombus. cardiac symptoms, usually in unhospitalized patients.[5,6,12,18,22–24] Previous clinicopathologic studies have shown that only a minority of patients with sudden cardiac death show evidence of discrete acute myocardial infarction or acute coronary occlusion.[5,6,12,18,22–24] The majority exhibit chronic coronary atherosclerosis and have no evidence of an acute coronary occlusion or a discrete myocardial infarct. However, they may have multifocal microscopic foci of hyperacute muscle cell injury characterized by myofibrillar hypercontraction.[18,24] These patients also frequently exhibit microthrombi and platelet aggregation in epicardial and intramural coronary arteries. However, the incidence of these lesions may not be substantially different in patients with sudden coronary death compared with that in patients with chronic coronary disease.[41–43]

Role of Coronary Thrombosis

Arguments for secondary role of coronary thrombosis in acute myocardial infarction: Variation in clinical and pathologic findings has led to differing interpretations of the role of acute coronary thrombosis and related lesions in the genesis of acute ischemic heart disease.[5–10,15,16,20,21,27,44–52] Several observations have been advanced to support the concept that coronary thrombi develop independently of acute myocardial infarction or as purely secondary phenomena relatively late in the course of acute myocardial infarction.[10,27,44–49] These observations include (1) the occurrence of coronary thrombosis without the development of acute myocardial infarction; (2) the small incidence of coronary thrombi in cases of sudden death; (3) the occurrence of myocardial infarction without demonstrable acute coronary thrombosis; (4) the greater incidence of coronary thrombi with relatively large infarcts and transmural infarcts, interpreted as indicating that larger infarct size predisposes to thrombus formation; (5) the large incidence of coronary thrombi with infarcts complicated by cardiogenic shock or severe congestive heart failure; (6) the frequent formation of coronary thrombi at sites of severe atherosclerotic narrowing in arteries that also frequently exhibit long stenotic segments, severe distal disease and prominent collateral anastomoses; and (7) results of initial radiofibrinogen tracer studies showing that coronary thrombi can incorporate tracer injected intravenously several hours after the clinical onset of myocardial infarction.[53,54]

Arguments in favor of a secondary role for coronary thrombi were stronger when available evidence suggested that patients with sudden cardiac death died at an early stage in the evolution of acute myocardial infarction.[10] However, more recent studies have indicated that the sudden cardiac death syndrome and acute myocardial infarction are separate entities with different pathogeneses. Most patients resuscitated from sudden cardiac collapse do not exhibit evidence of major myocardial infarction.[55–57] The sudden cardiac death syndrome appears to result from a primary arrhythmia, usually ventricular fibrillation, induced by an acute ischemic event not usually involving a major coronary thrombosis or by recurrent ventricular arrhythmia occurring in the setting of chronic coronary artery disease.[55–59] A corollary of this concept is that primary arrhythmogenic sudden cardiac death and sudden death induced by an arrhythmia during the course of acute myocardial infarction (secondary arrhythmia) are separate entities.

Arguments for a primary role of acute coronary thrombotic occlusion: Several observations strongly support the view that acute thrombotic occlusion generally exerts an important effect on the evolution of myocardial infarction.[7,15,16,20,21,51,52] Several postmortem studies, including this study, have shown (1) an association between acute coronary occlusion and regional myocardial infarcts, and a very large incidence of acute occlusion with regional transmural infarcts; (2) a spatial relation in most cases between the location of an infarct and an acute occlusion in the artery supplying the infarcted area; (3) a chronologic relation within the limits of the histologic method, between the age of the thrombi and the age of the infarcts; (4) lack of uniformity in the severity of atherosclerosis, including distal disease in arteries that manifest thrombi; and (5) the frequent association of coronary thrombi with the focal arterial lesions (plaque erosion, rupture and hemorrhage) that probably predispose to thrombus formation.[7,21,51,52,60–63]

Initial radiofibrinogen tracer studies suggested that thrombi formed relatively late in the course of infarction.[53,54] However, more recent studies have shown that radiofibrinogen becomes extensively incorporated into thrombi formed in experimental animals before the injection of tracer.[64,65] In addition, Fulton and associates[52,66] have reported that a radionegative central core can be demonstrated in most human thrombi, thus suggesting the initial occurrence of thrombus formation before injection of tracer.

Significance of Plaque Lesions Associated With Thrombi

Arguments have been advanced that coronary intimal plaque disruption and hemorrhage are produced artifactually by resuscitative efforts or by sectioning of the coronary arteries at autopsy. These arguments are contradicted by (1) the frequent association of plaque erosion, rupture and hemorrhage with occlusive thrombi, (2) the frequent association of plaque disruption with plaque debris admixed in the thrombus, and (3) by the histologic appearance of ruptured plaques suggesting disruption due to a force exerted from within the vessel wall and directed toward the lumen.[7,15,20,21,51,52,60–63] The relatively large plaque hemorrhages associated with plaque disruption and thrombosis appear to be derived primarily from influx of blood across the damaged plaque surface. In contrast, small petechial or microscopic hemorrhages frequently develop in plaques by extravasation from intraplaque vessels without associated plaque disruption and thrombosis.[63,67] In our study, the incidence rate of

plaque lesions with thrombi was 67.6 percent for infarcts aged 3 weeks or less. The apparent incidence rate decreased to 20 percent with older infarcts, probably because organization and healing made identification of these lesions more difficult. Other investigators, using serial section techniques, have found a very high incidence rate, usually greater than 90 percent, of plaque erosion and rupture associated with major plaque hemorrhages and acute coronary thrombi.[7,20,21,60–63]

Pathogenesis and causative factors: Plaque erosion, ulceration, rupture and thrombosis commonly occur in atherosclerotic vessels including the aorta and other diseased arteries in addition to coronary arteries. There probably is a variable and diverse pathogenesis for erosion, ulceration and rupture of plaques.[20,21,31,43,63] These phenomena typically involve plaques with prominent atheromatous cores and thin fibrous capsules (soft plaques or atheromas). Causative factors may involve chronic hemodynamic trauma, inflammatory or chemical injury to endothelium and subendothelial tissue, increased intraplaque pressure due to infiltration of blood and, finally, vasospasm in coronary arteries and other muscular arteries. In a recent study, evidence of coronary spasm was found in 6 (40 percent) of 15 patients with coronary atherosclerosis and acute myocardial infarction.[31] The histologic appearance of diseased coronary arteries indicates that an anatomic substrate for spasm frequently is present in the form of segments of well preserved medial smooth muscle in areas with eccentric plaques or less severe disease. However, uncertainty remains regarding the frequency and exact point at which coronary spasm occurs in the sequence of damage to the vessel wall, acute coronary occlusion and evolution of myocardial infarction.[36] Factors involved in this sequence may involve alterations in chemical mediators, such as prostacyclin and thromboxane A_2, platelet aggregation, a local or systemic increase in catecholamines, autonomic neural influences and systemic or local alterations in the clotting and fibrinolytic systems.[68–77]

Significance of Clinical Observations

Clinical correlations have indicated that myocardial infarction can have a variable pathogenesis. Clinical observations have also suggested an important role for acute coronary occlusion in the genesis of many myocardial infarcts. Pertinent clinical observations in this study were: (1) the high incidence rate of hemodynamic factors predisposing to reduced coronary perfusion with infarcts unassociated with coronary thrombi, in accord with the early observations of Friedberg and Horn[2]; (2) the low incidence of such predisposing factors with infarcts associated with coronary thrombi; and (3) the occurrence of coronary thrombi in the presence or absence of cardiac pump failure or congestive failure after onset of infarction. Walston et al.[8] reported a very large incidence of coronary thrombi with myocardial infarction complicated by cardiogenic shock and a small incidence of thrombi with infarcts unassociated with shock. However, other investigators[9,11] reported that smaller infarcts without shock and larger infarcts with shock had a similarly large incidence of coronary thrombi. Thus, the clinicopathologic findings in this and previous[9,11] studies negate the argument that formation of coronary thrombi can be explained on the basis of a generalized impairment in coronary perfusion after the onset of myocardial infarction.

Myocardial Versus Coronary Factors in Myocardial Infarction

Additional considerations have been raised regarding the pathogenesis and effects of acute coronary thrombosis. Some investigators[27,45–47,50] have emphasized that the potentially detrimental effects of an acute coronary occlusion can be counteracted by a coronary collateral system sufficient to maintain blood flow distal to an acutely occluded segment. A further proposal is that myocardial infarction is initiated by subendocardial ischemia resulting from some impairment in the myocardial oxygen supply/demand ratio that does not involve coronary thrombosis. In many cases, the important initiating factor may be a circulatory derangement that decreases coronary perfusion and elevates left ventricular end-diastolic pressure creating a hemodynamic vise in the subendocardium.[50] Vasospasm of small coronary arteries also may be an initiating or contributory factor.[35,48,49] The hypothesis has been advanced that increased vascular resistance in the ischemic or infarcted myocardium could lead to reduced flow and stasis in the arterial system supplying the region. This may be followed by thrombus formation at a site of maximal obstruction and possibly also by plaque rupture and hemorrhage.[27,45–49] Generalized impairment in coronary perfusion has been proposed as a major contributing factor in this process.[44] It has also been proposed that collateral flow around a stenotic segment could contribute to thrombus formation in addition to minimizing a major functional effect of the occlusion.[27,45–49] The latter argument has been linked to the observation that coronary bypass grafting can create a state of competitive flow that predisposes to thrombus formation at the anastomosis and in the proximal artery.[27] Thus, proponents of the extreme form of the myocardial hypothesis regard thrombosis as a frequent secondary event of little functional consequence in myocardial infarction.

The possibility that myocardial factors contribute to the evolution of infarction is intriguing. It is conceivable that some thrombi form without plaque disruption in extensively and severely stenotic arteries in response to increased myocardial vascular resistance and vascular stasis.[10] Experimental studies have shown that increased vascular resistance and reduced reflow develop in the necrotic subendocardium after 90 to 120 minutes of coronary occlusion in the dog.[78,79] However, the extreme form of the myocardial hypothesis is highly speculative. From this hypothesis, it is difficult to explain the variable occurrence of infarction without thrombosis and thrombosis without and with infarction. Postmortem studies have not provided an adequate

explanation for these phenomena on the basis of anatomic differences in extent of coronary collateral development.[45,46] However, there is general agreement that coronary collateral flow in some instances can compensate for acute occlusion so that no myocardial necrosis results.[3,4,27,45–52] Another reasonable conclusion is that variations in the extent of generalized coronary atherosclerosis and of coronary collateral flow influence whether an acute coronary occlusion is followed by no infarct, a subendocardial infarct or a transmural infarct.[3,4,51,52] The positive correlations between coronary occlusions and regional infarcts, transmural infarcts and infarct size[27] strongly suggest that an acute occlusion, typically in the form of a thrombus, usually acts as a major factor in determining the final extent of an evolving myocardial infarct. Furthermore, the frequent association of coronary thrombosis with plaque erosion, rupture and hemorrhage strongly suggests that the key initiating event in thrombus formation occurs in the coronary artery.

Conclusions

A broad perspective on the spectrum of acute ischemic heart disease directs major emphasis to the triggering mechanisms that initiate acute clinical events, including the sudden cardiac death syndrome and acute myocardial infarction with or without associated acute coronary occlusion. Earlier studies have clearly established that acute events can be precipitated by factors that increase myocardial oxygen demand or reduce cardiac or coronary reserve.[2–4] Recent studies[30–36,68–77] have suggested the potential importance of additional factors, such as platelet alterations, imbalance in the prostacyclin-thromboxane A_2 system and altered adrenergic function and the probable influence of these factors on induction of coronary arterial spasm. In this broader context, coronary thrombosis should not be considered in purely primary or secondary terms but as a contributing factor of frequently major importance in the evolution of the dynamic pathophysiologic events that constitute acute ischemic heart disease.

Certain observations related to coronary thrombosis appear important in the selection of patients for some forms of therapy such as anticoagulation and intracoronary administration of fibrinolytic agents.[80–83] These observations include the large incidence of coronary thrombosis with transmural infarcts, the variable incidence of thrombosis with subendocardial infarcts and its frequent association with plaque disruption. The characteristic clinicopathologic features of various ischemic heart disease syndromes also should be considered in the design and evaluation of studies dealing with pharmacologic interventions, definition of risk groups and development of prognostic criteria.

Addendum

De Wood and associates[84] reported clinical coronary arteriographic findings in 322 patients admitted within 24 hours of acute transmural myocardial infarction. The overall incidence rate of total coronary occlusion was 79.8 percent, with incidence rates of 85 to 87 percent within the first 6 hours of infarction and 65 to 68 percent at 6 to 24 hours. A substantial incidence rate of subtotal occlusion (greater than 95 percent narrowing) also was noted. In 79 patients who were undergoing emergency coronary bypass surgery, fresh thrombi were recovered from the coronary arteries of 57 (72.2 percent). Thus, the clinical findings of De Wood and associates[84] confirm the autopsy evidence of a very high incidence rate of occlusive coronary thrombosis with regional transmural infarction.

Response of the Left Ventricle to Stress: Effects of Exercise, Atrial Pacing, Afterload Stress and Drugs

ROBERT SLUTSKY, MD

San Diego, California

A variety of tests are being utilized today to diagnose the presence of ischemic heart disease, assess the prognosis of myocardial and valvular heart disease and evaluate the effects of various pharmacologic agents on cardiac performance. This review summarizes the current evidence regarding the response of left ventricular performance and size to atrial pacing, afterload stress and various forms of exercise. The response in normal persons and in subjects with coronary heart disease is reviewed and, when applicable, the effects of various pharmacologic agents on exercise performance in these patient groups are examined.

In 1959, Rushmer et al.[1] noted that deficiencies in our basic understanding of accepted hemodynamic theories often are corrected with the introduction of new or improved techniques. Although this observation was made more than 2 decades ago in an article about the ventricular response to exercise in animal preparations, the comments are still applicable. It is agreed that the cardiac response to exercise and other forms of stress is complex, but only recently have contrast ventriculography, radionuclide angiography and echocardiography been applied to the heart under stress. In particular, left ventricular function and size can now be serially evaluated with either the radionuclide or the ultrasonic technique without important alterations in loading conditions.

The goal of this review is to discuss the effects of exercise, atrial pacing, afterload stress and isoproterenol on left ventricular size and function in normal subjects and patients with coronary heart disease. The specific effects of supine and erect bicycle exercise, treadmill exercise and isometric (handgrip) exercise will be considered.

Exercise

Supine Bicycle Exercise (Fig. 1)

Normal subjects: End-diastolic volume at rest is near maximum when a subject is reclining, smaller when he is sitting and smallest when he is standing.[2–4] Thus, during supine exercise, only occasionally do alterations in preload play an important role in the normal subject.[4–10] During exercise, myocardial shortening increases, end-systolic volume declines and left ventricular end-diastolic pressure increases slightly.[5,6,10] Additionally, systolic blood pressure and left ventricular systolic pressure increases,[5,6,11] but there is little change in the diastolic pressure-volume relation.[6] In most studies, left ventricular ejection fraction increases with exercise in 80 to 100 percent of normal subjects,[4–6,11–14] although this change has not been found by all investigators[15] and may vary with patient populations[16] and the presence of other illnesses.[11,17] Similarly, right ventricular ejection fraction increases,[18,19] with little change in right ventricular end-diastolic volume.[20]

Patients with coronary artery disease: The presence of significant coronary heart disease alters these findings. Patients with ischemic disease, even in the absence of angina pectoris, are often unable to exercise to work loads or heart rates equal to those of normal control subjects.[7,11,13,18] Usually there is little if any increase in end-diastolic volume during exercise and an elevation in end-diastolic pressure, with

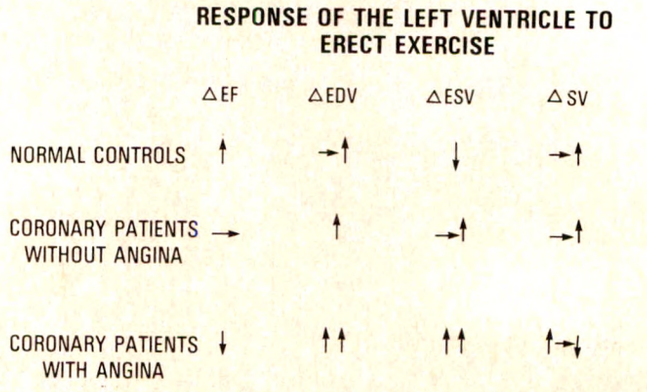

FIGURE 2. Hemodynamic responses to erect bicycle exercise. Abbreviations and symbols as in Figure 1.

no change or an increase in end-systolic volume.[5–7,11,21] Wall motion disorders may appear. If angina is produced during supine exercise, there may be modest to marked ventricular dilatation, with a greater increase in end-systolic volume and a reduction in ejection fraction.[5–7] Many of these exercise-induced abnormalities in left ventricular size and function may be reversed by pretreating the patient with sublingual nitroglycerin or nitroglycerin paste prior to the exercise study.

Erect Bicycle Exercise (Fig. 2)

Hemodynamic effects: The published data on erect bicycle exercise are fewer than on supine exercise, as might be expected from the technical ease with which supine studies may be performed and the difficulty with imaging the erect, exercising patient. Sitting erect produces smaller resting end-diastolic volumes than those obtained by lying flat.[2,22,23] Similarly, left ventricular end-diastolic pressure, pulmonary capillary wedge pressure, cardiac index and stroke volume index are less in the erect than in the supine position.[24,25] In the normal subject during erect exercise, cardiac index and stroke volume index both increase, as do systolic pulmonary capillary wedge and left ventricular end-diastolic pressures.[24] In patients with ischemic disease, pressures increase even more markedly during exercise. In subjects who experience angina during exercise in the supine position, cardiac index and stroke volume index are similar to those of supine values at rest, whereas in the erect position, although angina develops and pressures increase, cardiac index and stroke volume index may still be greater than at rest.[25]

Radionuclide angiography: A variety of recent noninvasive studies have analyzed the response of ventricular size and function to erect exercise.[4,26,27] Rerych et al.,[26] using first-pass radionuclide angiography, evaluated both normal subjects and patients with coronary heart disease during erect bicycle exercise. They found that during exercise the heart rate doubled, the cardiac output tripled and the ejection fraction increased in normal subjects. In addition, there was a minimal increase in end-diastolic volume and a marked reduction in end-systolic volume. In patients with coronary disease, the ejection fraction tended to remain unchanged or decreased with exercise, in association with an increase in end-diastolic and end-systolic volumes. They found that the greater the severity of the coronary disease, the more marked the ventricular dilatation.

Echocardiography: In an echocardiographic study involving semi-supine exercise, Weiss et al.[27] found that marked ventricular dilatation occurred with exercise, with little change in end-systolic volume. Crawford et al.[4] were unable to confirm this degree of dilatation in their supine or erect patients. At present the data from these angiographic and echocardiographic studies,[4,26,27] indicate that during erect exercise, normal subjects have an increase in ejection fraction due to a modest reduction in end-systolic volume, perhaps some degree of ventricular dilatation, and an increase in stroke volume. Patients with coronary heart disease manifest some degree of left ventricular dilatation, along with an increase in end-systolic volume and stroke volume, and a decrease or little change in ejection fraction. End-diastolic volume may not prove to be as important during protracted exercise as during brief bursts of exertion.[28]

Regional pulmonary and cardiac blood volumes: Using a multicrystal positron camera and ^{11}C-carboxyhemoglobin, Nichols et al.[29] examined the effects of upright exercise on regional pulmonary and cardiac blood volumes. In patients with single vessel coronary disease or normal coronary arteries, regional blood volume was unchanged in the upper and lower pulmonary lung fields during exercise, and total cardiac volume was reduced during stress. In patients with multivessel disease, blood volume increased in the upper and lower lung fields with exertion, in association with an increase in cardiac volume. A related study from Okada et al.[30] reported similar blood volume data from the pulmonary bed. Thus, the increase in left ventricular end-diastolic pressure during exercise leads to pulmonary congestion and increased pulmonary blood volume. With more widespread coronary disease, these findings become more prominent, and as might be expected, congestion more marked.

Treadmill Exercise and Upright Exercise

Animal studies: Because treadmill exercise involves fairly active exertion, and presents substantial difficulties with respect to pressure monitoring and cardiac imaging, few data during exercise are available in human subjects. A number of studies involving animals yield information that in all likelihood can be extrapolated to human subjects. Rushmer[31] reported that the most striking response to upright exercise in dogs was an increase in heart rate, with modest increase in stroke volume (rarely exceeding 30 percent of resting values). In addition, left ventricular diameter decreased. Barger et al.[32] found a linear relation between oxygen consumption and cardiac output during graded exercise, and described a variable stroke output response using that technique. Horwitz et al.[33] found similar results in exercising dogs. These data suggested that increased stroke volume is not a necessary feature of standing exercise. Vatner et al.[34] analyzed the left ventricular response to severe exercise by telemetry of direct cardiac measurements. They found that with severe exercise in tethered dogs, stroke volume increased 30 percent, heart rate tripled and thus cardiac output quadrupled. Left ventricular end-diastolic pressure rose (200 percent), but end-diastolic dimension increased only slightly (less than 1 percent) and end-systolic dimension decreased a similarly small amount. Thus the major change in cardiac output was related to heart rate rather than to substantial alterations in cardiac size.

Hemodynamic response in human subjects: Information in human beings about the hemodynamic response to treadmill exercise is mostly indirect. The major physiologic variables that have been measured included maximal oxygen consumption, heart rate, blood pressure, ventilatory volume and respiratory quotient.[35] Maximal oxygen consumption is the highest level of oxygen that an ambulatory person can extract, and equals cardiac output times the arteriovenous oxygen difference. In general, maximal arteriovenous oxygen difference is a constant[36]; thus, within each person, maximal oxygen consumption reflects cardiac output, and thus the limits of that person's cardiovascular system. Although the data are predominantly inferential, increases in heart rate appear to produce the most substantial part of the increase in cardiac output and maximal oxygen uptake. Stroke volume in all likelihood increases slightly.

Radionuclide angiographic studies: In a recent radionuclide study, Battler et al.[37] evaluated ejection fraction changes in the immediate recovery period after exercise. In their study, both normal subjects and patients with coronary disease had a normal ejection fraction before exercise. Additionally, in the immediate recovery period (2 to 4 minutes after completion of the exercise study) normal subjects had an increase in ejection fraction over the resting supine ejection fraction (mean ± standard error of the mean 0.61 ± 0.03 to 0.78 ± 0.06), which remained elevated even 10 minutes after completion of the study (0.73 ± 0.05). Patients with coronary artery disease had a mean post-treadmill ejection fraction that was insignificantly greater than the value at rest (0.59 ± 0.06 to 0.64 ± 0.06) and that returned to the baseline value by 10 minutes after the study. These subjects also underwent supine exercise bicycle exercise, in which the peak exercise ejection fraction was lower for both the normal subjects and patients with coronary disease. Unfortunately, the volume response was not evaluated in this study.

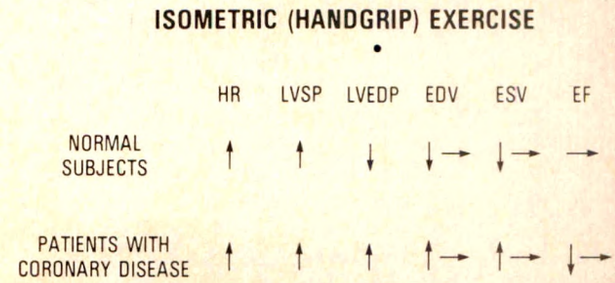

FIGURE 3. Hemodynamic responses to handgrip exercise. HR = heart rate; LVEDP = left ventricular end-diastolic pressure; LVSP = left ventricular systolic pressure; other abbreviations and symbols as before.

Obtaining radionuclide or echocardiographic data during treadmill exercise is practically impossible. Newer radionuclide monitoring devices that may be worn rather than positioned[38] would be of inestimable value in making such analyses more feasible.

Isometric (Handgrip) Exercise (Fig. 3)

Sustained muscular activity directed against an immobile object has been of significant value in providing a reproducible method for producing circulatory alterations directed at stressing the heart. Handgrip exercise is the most convenient and popular form of this type of stress.

Flessas et al.[39] used contrast ventriculography to evaluate the response of left ventricular volume and pressure to handgrip exercise. Normal persons manifested an increase in heart rate and systemic and left ventricular systolic pressures, together with a decrease in end-diastolic pressure, end-systolic volume and stroke volume. End-diastolic pressure declined; cardiac output and ejection fraction increased slightly. A similar study[40] using echocardiography in normal adolescents revealed little change in cardiac volumes and ejection phase indexes during handgrip exercise. Cardiac output increased because of an increase in heart rate. In patients with coronary heart disease, the response is variable, although most patients manifest new wall motion abnormalities[41] or other hemodynamic disturbances.[39,42–44] Most patients with coronary disease also have marked increases in left ventricular systolic and diastolic pressures, with reductions in cardiac volumes and often ejection fraction as well. In a study of patients after cardiac surgery, Savin et al.[45] found that handgrip exercise induced a slight reduction in ejection phase indexes along with a slight increase in end-diastolic and end-systolic volumes. These changes were more marked in subjects with an innervated than in those with a denervated heart, probably in part because of the lesser increase in heart rate in the latter patients.

Thus, although the data vary somewhat, handgrip exercise produces elevations in pressure and heart rate. In normal subjects, cardiac volumes decrease, ejection phase indexes in most studies remain unchanged and end-diastolic pressure declines. In patients with coronary disease, end-diastolic pressure increases, end-diastolic and end-systolic volumes increase or remain the same, stroke volume declines and ejection phase indexes decline or remain the same (Fig. 3). Wall motion abnormalities are either exacerbated or newly appear. This latter phenomenon is the most useful discriminator between normal subjects and patients with coronary disease.

Effects of Propranolol on Cardiac Performance During Exercise

Propranolol is one of the most commonly prescribed drugs in patients with cardiovascular disease. To provide an overall picture of its effect, I will review it here as a separate entity rather than separately with each exercise section.

The mechanisms by which beta adrenergic blockade provides relief of angina pectoris in patients with coronary heart disease have been extensively studied. Presumably, myocardial oxygen requirements are reduced, probably reflected by a reduction of heart rate-blood pressure product during exercise. In normal subjects, propranolol produces a reduction in heart rate and blood pressure; left ventricular dilatation occurs, but there is no change in myocardial shortening.[46,47] Similar results are seen in patients with coronary disease.[48–50]

Supine exercise: During supine exercise in normal subjects, heart rate was slower, blood pressure lower, left ventricular dimensions larger and percent shortening reduced.[46] Similar results were seen using radionuclide angiography.[50,51] The response in patients with coronary heart disease is somewhat more complicated. Battler et al.[49] analyzed the ejection fraction response to exercise in patients who manifested angina and electrocardiographic evidence of ischemia (greater than 1 mm S-T depression) during both treadmill and supine bicycle exercise. They found that propranolol reduced both heart rate at rest and during exercise, blood pressure during exercise and rate-pressure (double) product both at rest and during exercise. Resting ejection fraction remained unchanged, but the peak exercise ejection fraction was higher during treatment. Wisenberg et al.[51] found little change in peak exercise ejection fraction in patients with coronary artery disease after treatment with propranolol, although it was not clear if these patients manifest ischemia during exercise. Rainwater et al.[52] reported improvement in exercise perfusion and function in patients with reversible ischemia, though not in patients with previous infarction. Both Battler[49] and Rainwater[52] and their co-workers suggest propranolol may improve regional myocardial perfusion. Intravenous propranolol has a more marked negative inotropic effect, which can be seen at rest and during supine exercise in patients with coronary disease.[53] At present, few data are available on the volume response to supine exercise in patients with ischemic disease on and off oral propranolol.

Erect bicycle or treadmill exercise: Similar to supine exercise, during either erect bicycle or treadmill exercise, the most consistent effect of oral propranolol was a reduction of rest and exercise pressure-rate products, a slowing of heart rate, and an increase in resting stroke volume.[54] Using first-pass radionuclide angiography, Port et al.[55] evaluated the left ventricular response to erect bicycle exercise in normal subjects pre- and post-administration of oral propranolol (320 mg/day) for 2 days. After propranolol administration, cardiac output and ejection fraction was reduced at rest. During exercise, heart rate, systolic blood pressure, ejection fraction and cardiac output were lower and end-systolic volume higher than at comparable control stages during exercise. End-diastolic volume was also slightly greater at rest and peak exercise after propranolol. Few data are available regarding the response of patients with ischemic heart disease in the erect position to either intravenous or oral propranolol.

Atrial Pacing (Fig. 4)

Normal subjects: Increases in heart rate represent a positive inotropic stimulus, independent of other factors influencing ventricular performance such as the autonomic nervous system.[56–58] In both animal and human studies,[59] velocity ejection phase indexes increase with increases in (paced) heart rate. In this latter study, DeMaria et al.[59] found that fractional shortening declined during atrial pacing in normal subjects. Similar results were reported by Krayenbuehl et al.,[60] who found that ventricular volumes declined during atrial pacing in normal control subjects, along with little change in ejection fraction. Velocity indexes in this study increased. In a radionuclide study, Tzivoni et al.[61] reported a small insignificant increase in ejection fraction during atrial pacing in normals. The pacing rates in the latter study was greater than in the previously mentioned studies. In all studies involving normal subjects and patients with coronary artery disease, little change was found in cardiac output, systemic arterial pressure and peripheral vascular resistance. Analysis of regional shortening velocities demonstrated increases in regional contraction in normal subjects during pacing.

Patients with ischemic heart disease: In these patients ejection fraction decreases or remains un-

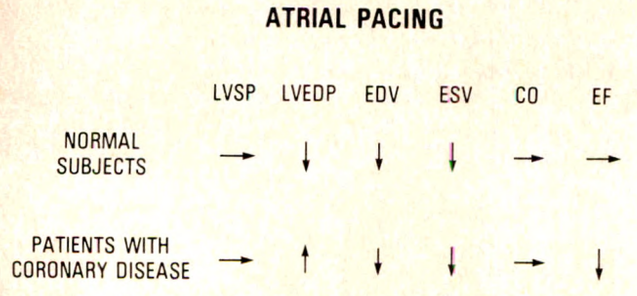

FIGURE 4. Hemodynamic response to atrial pacing. CO = cardiac output; other abbreviations and symbols as before.

changed[60–64] and regional wall motion is modestly altered.[60] If ischemia is produced, volumes may not decrease as markedly,[62,63,65] and end-diastolic pressure may increase.[61,62,65] Ischemia produces regional wall motion abnormalities,[63–65] although subjects with normal coronary arteries may also manifest septal wall motion abnormalities at higher pacing rates.[64] Studies in dogs with experimental coronary stenosis indicate that pacing-induced regional dysfunction persists in the post-pacing period. Later in a study involving patients with ischemic heart disease, Ricci et al.[66] found that, after pacing, control segments had greater regional shortening (when compared with values at rest), whereas myocardial regions supplied by stenotic vessels demonstrated reduced regional shortening. More than 90 percent of segments in compromised regions deteriorated, whereas 85 percent of segments in normal regions improved.

Thus, atrial pacing results in a reduction in cardiac size in normal subjects, with little change in ejection fraction, cardiac output or peripheral vascular resistance. Velocity indexes increase. In patients with ischemic heart disease, ventricular volumes decline, ejection fraction decreases or remains unchanged (although velocity indexes may not) and new wall motion abnormalities may appear, particularly immediately after pacing. In addition, end-diastolic pressure increases. Cardiac output does not change because stroke volume declines in proportion to the increase in heart rate.

Afterload Stress

Normal subjects: Many investigators have both recommended and investigated the use of altered systemic arterial pressure as a means of examining the contractile reserve of the left ventricle.[67–71] In normal subjects, with elevation of arterial pressure, a shortening velocity and isovolumic indexes of cardiac performance are reduced and end-diastolic and end-systolic volumes increase.[72–74] The predictability and reproducibility of these changes have been utilized to examine the effects of pharmacologic agents on left ventricular performance.[46,75,76] In association with ventricular dilatation, end-diastolic pressure[74] and cardiac output[72] increase.

Patients with noncoronary heart disease: Relatively little information is available in patients with coronary heart disease. In patients with noncoronary heart disease, increases in left ventricular and systemic pressure produce reductions in ejection phase indexes of left ventricular performance and increases in end-diastolic and end-systolic volumes. Both peak and mean wall stress increase.[77] It has been suggested that patients with chronic aortic insufficiency may be classified into subgroups depending on their response to pressure stress.[71] In one subgroup, an increase in pressure produced an increase in stroke work index and a modest reduction in ejection fraction. In the second group, the stroke work index declined with elevations in arterial pressure, usually with a reduction of resting ejection fraction to below 0.50. These patients were postulated to have latent or subclinical disturbances in contractile reserve.[71] Various studies involving other cardiac diseases in adults and children have previously been described,[78–81] none yielding as much clinical information as the study involving subjects with aortic insufficiency.

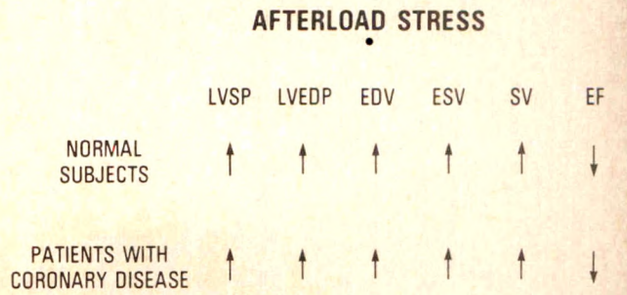

FIGURE 5. Hemodynamic responses to elevation in systemic arterial pressure by pharmacologic infusions. Changes in both patients and normal subjects are similar; however, as might be expected, alterations in end-diastolic volume (EDV) will vary with the volume status of the subject and the compliance characteristics of the individual ventricle. Abbreviations and symbols as before.

Patients with coronary artery disease (Fig. 5): Watkins et al.[82] evaluated both normal subjects and patients with coronary heart disease using equilibrium (gated) radionuclide angiography and phenylephrine. They found that the slope of the relation between systolic blood pressure and end-systolic volume was linear in all subjects ($r \geq 0.91$). End-systolic, end-diastolic and stroke volumes all increased with elevations in systemic pressure and ejection fraction, ejection rate and mean velocity of circumferential fiber shortening decreased. Normal subjects had a slightly greater slope to the end-systolic pressure/systemic volume relation, and a smaller Vo (theoretical end-systolic volume at an extrapolated zero pressure). However, they did not find the slope of the pressure/volume ratio superior to the resting ejection fraction in discerning normal subjects from patients with coronary heart disease. Thus, as previously suggested,[83] elevation in systemic pressure impedes systolic ejection, resulting in acute ventricular dilatation and reduced indexes of ventricular performance. The clinical utility of this technique is primarily restricted to examination of different pharmacologic agents at present.

Isoproterenol Stress

Comparison with exercise stress: The use of isoproterenol infusion to simulate exercise testing has been proposed to study pediatric patients and patients with valve stenosis.[84–86] Because isoproterenol is known to increase myocardial oxygen demand by enhancing myocardial contractile state and increasing heart rate,[87–90] it has been offered in conjunction with electrocardiographic monitoring as an alternate to electrocardiographic exercise testing.[91] Kuramoto et al.[92] found that in young men (mean age 23 years), isoproterenol infusions of 0.02 and then 0.09 μg/kg per min caused an increase in heart rate, cardiac index and stroke index similar to that caused by bicycle ergometric exercise of 50 and 100 watt seconds. Whereas bicycle exercise increased pressures, isoproterenol reduced

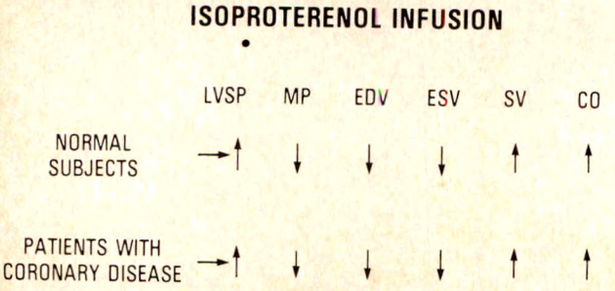

FIGURE 6. The hemodynamic response to isoproterenol infusion is displayed. MP = mean arterial pressure; other abbreviations and symbols as before.

diastolic and mean blood pressure. In an older patient population (mean age 73), the mean maximal bicycle exercise work load was 40 watt seconds. The changes in heart rate, blood pressure and cardiac performance were identical to those of the younger subjects at this work load. After isoproterenol, the increase in cardiac index and stroke index was less in old than in young men, showing either a decreased response to beta adrenergic stimulation or a limited reduction in the "afterload" effect of the drug due to the compliance characteristics of the vessels of the older patients.

Experimental effects: Battler et al.[93] evaluated the effects of isoproterenol on regional function in dogs with mild coronary stenosis. In the absence of an arterial occluder on a coronary artery, isoproterenol produced an increase in normal regional function. After partial occlusion, which produced no regional resting abnormalities, isoproterenol at small dosages (0.02 μg/kg per min) produced a significant decrease in wall thickening, which continued for a short time even after isoproterenol was discontinued, and returned to normal 5 minutes after the infusion was stopped. They concluded that with mild partial coronary stenosis that does not produce electrical or mechanical disturbances, small dose isoproterenol rapidly induces regional myocardial dysfunction and S-T alterations.

Clinical effects (Fig. 6): Isoproterenol is known to produce improvement in cardiac performance in patients with low cardiac output[94,95] because of its potent beta adrenergic effects, although this may not occur in patients with coronary heart disease.[96] Nonetheless, it has clearly been shown[97] that isoproterenol infusions induce: (1) a reduction in systemic vascular resistance; (2) an increase in cardiac output and index, and (3) an increase in ejection fraction with a reduction in both end-diastolic and end-systolic volumes. Similar results were seen in both normal subjects and patients with heart disease.

Conclusion

The ability of the ventricle to adapt itself to work requirements has allowed the creative investigator to stress the heart in any of a number of ways. These methods have included aerobic and anaerobic exercise as well as infusions of agents that alter preload, afterload and inotropic state. Most commonly, the aim has been to induce a degree of regional ischemia or left ventricular dysfunction that can be measured and quantitated by either surface electrocardiography, noninvasive cardiac imaging or intracardiac pressure and volume monitoring. The test, the agent and the measuring device all will vary depending on the original purpose of the protocol. It has been the goal of this review to clarify the basic ventricular responses to these interventions to facilitate these varied investigations, and to point the physician toward the intervention that is most likely not only to provide the answer to the clinical or physiologic question, but also to allow the question to be asked.

Acknowledgment

The long, arduous and continuous assistance of Joel S. Karliner, MD, in the review of this manuscript and in my development as an investigator is sincerely appreciated.

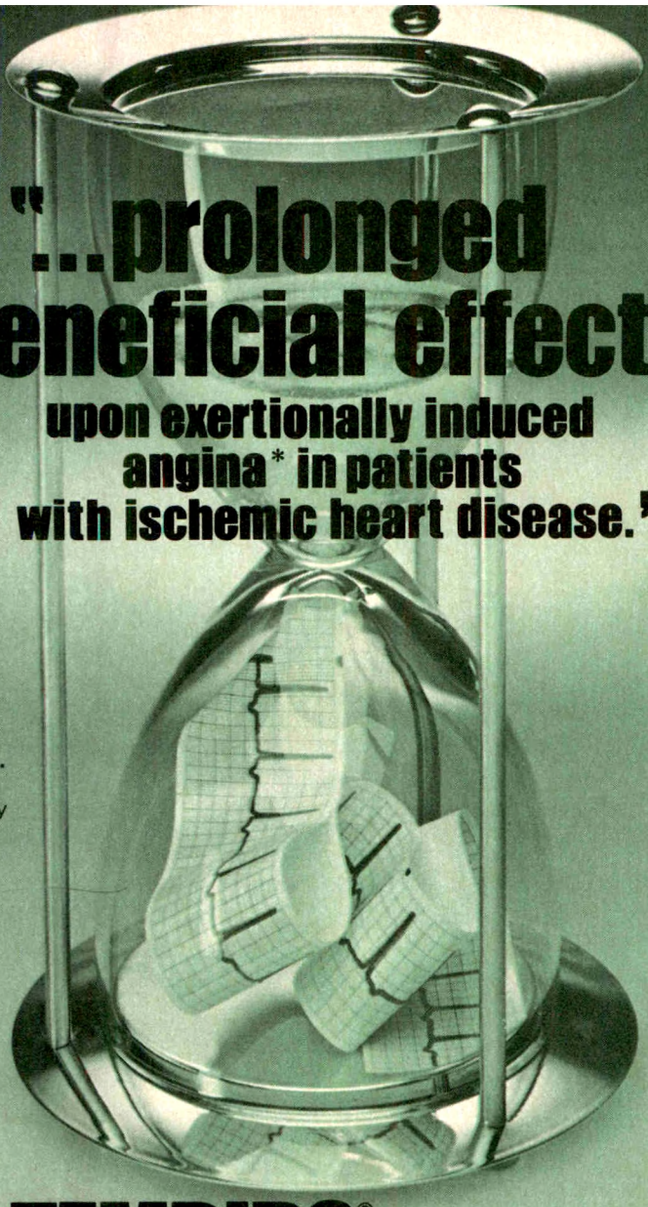
"...prolonged beneficial effects

upon exertionally induced angina* in patients with ischemic heart disease."[1]



A double-blind, controlled study of 28 patients employing maximal treadmill exercise stress tests.

Antianginal efficacy of oral therapy with isosorbide dinitrate capsules. Lee G, Mason DT, Amsterdam EA, Miller RR, and DeMaria, AN. *Chest* 73:327-333, 1978.

ISORDIL® TEMBIDS® CAPSULES

(ISOSORBIDE DINITRATE) SUSTAINED-ACTION CAPSULES, 40 mg

- **gradual release provides up to ten hours of sustained prophylaxis against angina pectoris attacks**
- **bid dosage is frequently satisfactory to prevent angina attacks...dosage range 1 capsule bid to qid**
- **stable...retains potency without significant loss or variation under normal conditions (room temperature, c 73 F)**

***Indications:** Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:
"Possibly" effective: When taken by the oral route, Isordil is indicated for the relief of angina pectoris (pain of coronary artery disease). It is not intended to abort the acute anginal episode, but is widely regarded as useful in the prophylactic treatment of angina pectoris.
Final classification of the less-than-effective indications requires further investigation.

Contraindication: Idiosyncrasy to this drug.

Warnings: Data supporting the use of nitrites and nitrates during the early days of the acute phase of myocardial infarction (the period during which clinical and laboratory findings are unstable) are insufficient to establish safety.

Precautions: Tolerance to this drug and cross-tolerance to other nitrites and nitrates may occur.

Adverse Reactions: Cutaneous vasodilation with flushing. Headache is common and may be severe and persistent. Transient episodes of dizziness and weakness as well as other signs of cerebral ischemia associated with postural hypotension may occasionally develop. This drug can act as a physiological antagonist to norepinephrine, acetylcholine, histamine, and many other agents. An occasional individual exhibits marked sensitivity to the hypotensive effects of nitrite, and severe responses (nausea, vomiting, weakness, restlessness, pallor, perspiration and collapse) can occur even with the usual therapeutic dose. Alcohol may enhance this effect. Drug rash and/or exfoliative dermatitis may occasionally occur.

Consult direction circular before prescribing.

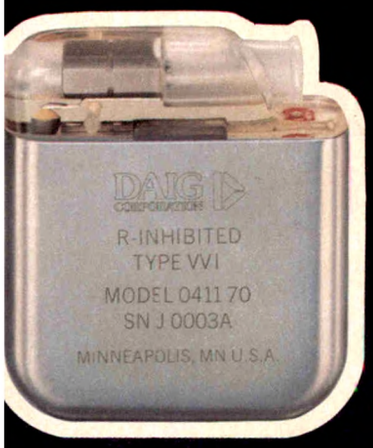
nnovation...

hree new pacemakers o meet or surpass your xpectations.



When your patient needs a simple demand pacemaker.

Our new Lithicron III 411 offers the benefits of proven circuitry and reliable lithium power source*, backed by eight years of clinical history. All designed in a unit that is our smallest model yet.

Our current reliability study on Daig pacemaker technology is based on nearly 00 million hours of pacing.

When your patient needs a multi-programmable pacemaker.

Our new Lithicron 515 allows alterations of rate, pulse width, output, sensitivity, refractory, mode, and features telemetry confirmation . . . and all in the confines of an 11 mm thin configuration.

When your patient needs atrially associated pacing.

Our new VISA pacemakers, Models 520/620 are two of th most advanced pacemakers or the market, giving the patient complete physiological contro of rate in order to adapt to periods of rest and exertion. Simulating normal cardiac activity, P-wave synchronous pacing greatly improves cardia performance.

Experience

ur Permanent Pacing eads offer a complete election of tip configurations, odel lengths, and connector ssemblies. Designed for ability and reduced current ain they are compatible with e majority of today's pulse enerators.

ur external pacemaker, patient onitors, pacemaker rogrammers, temporary leads, ad introducers, adaptors and ccessories complete this full ervice product line that meets l your pacing needs.

CARDIOLOGY UPDATE, 1981: Reviews for Physicians

Elliot Rapaport, M.D., Editor-in-Chief, Professor of Medicine, University of California, San Francisc Cardiology Service, San Francisco General Hospital, San Francisco, California.

The latest volume in the acclaimed *Cardiology Update* series, the 1981 edition contains important n subject matter of current interest to cardiologists, internists, cardiovascular surgeons, house office and students. Topics include: new developments in phonocardiography, emissive tomography, co puterized interpretations of electrocardiograms, the management of hypertension, and clinical expe ence with the newer antiarrhythmic agents.

1981 392 pages Cloth $29.95

Now The European Journal of Cardiology becomes...

THE INTERNATIONAL JOURNAL OF CARDIOLOGY

Editor-in-Chief: John A. Kastor, M.D., Professor of Medicine, University of Pennsylvania, Phi delphia, Pennsylvania—plus an outstanding editorial board drawn from the international community cardiologists.

Already hailed as one of the world's most prestigious cardiology journals, **The European Journal Cardiology** is now changing its name to better reflect its broad international scope and quality. N called **The International Journal of Cardiology,** it will continue to publish the best and most signific basic and clinical research being done today—and to provide practicing clinicians and researchers w an authoritative forum for worldwide progress in their field.

To mark this significant development in the journal's history, the publishers are pleased to announce t introduction of a *personal subscription rate,* bringing **The International Journal of Cardiology** wit easy reach of individual subscribers.

Subscription Rates Including Postage: Personal Rate: $38.00/Dfl. 74.00, Institutions: $93.75/Dfl. 183.00., (1981, 1 Volume in 6 Issues)

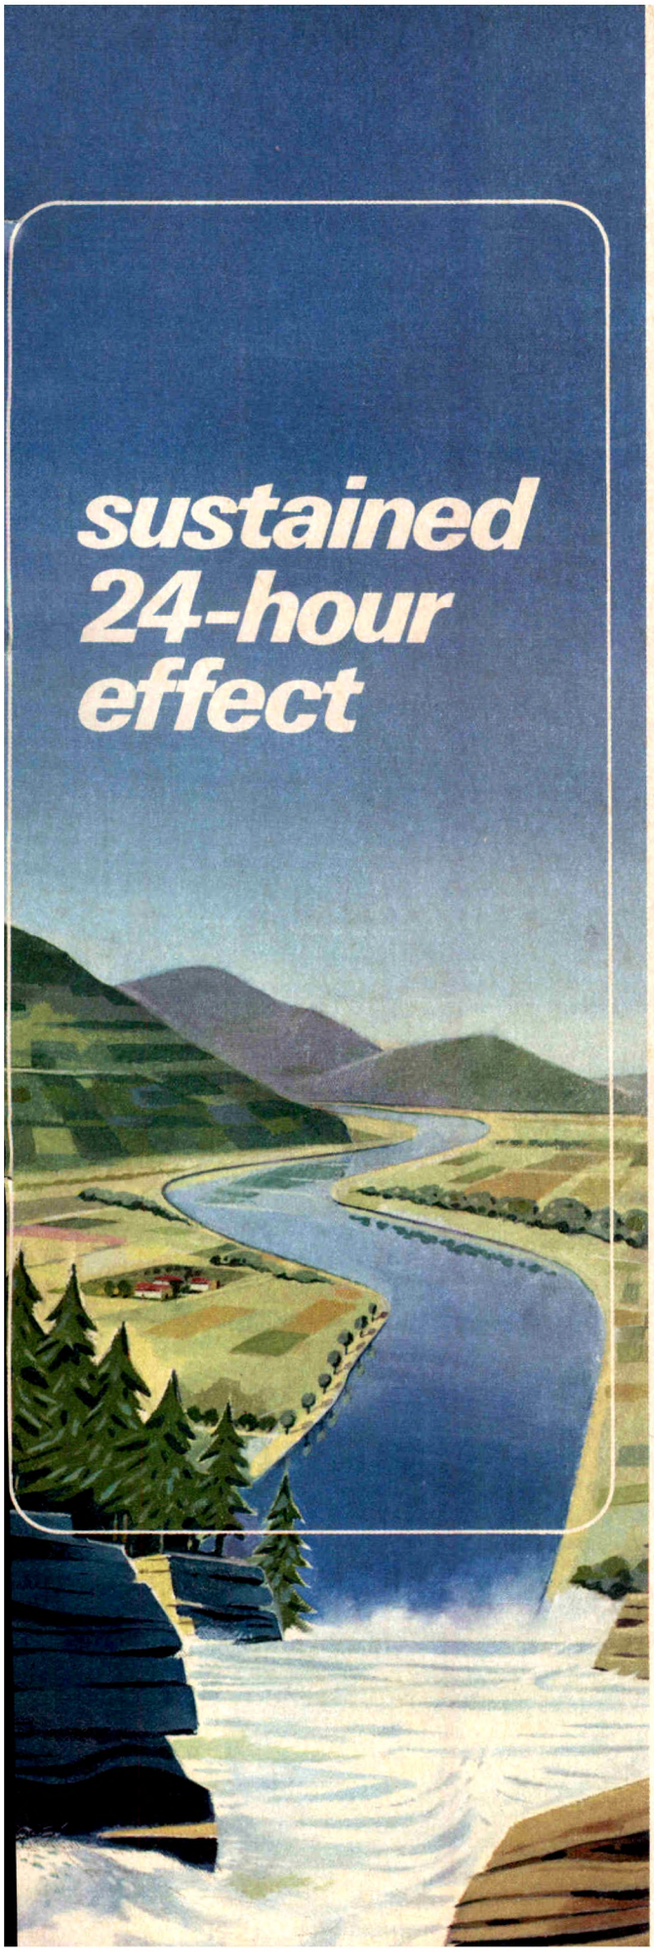
In mild to moderate edema of CHI
DIULO™ 10 MG
(METOLAZONE)
rapid, moderately
potent diuresis



Diulo (metolazone) 10 mg Indicated for use in chronic CHF

In acute pulmonary edema, dramatic volume depletion is desirable. That's why agents capable of producing profound diuresis within a few hours are indicated. But where smooth, prolonged effect is desirable – as in patients with chronic CHF, whether they be bedridden and elderly, ambulatory, or have low GFRs – a single, oral, therapeutic dose of Diulo produces effective natriuresis for up to 24 hours.

With Diulo 10 mg, your patient with chronic CHF benefits from effective diuretic action. But unlike those receiving more potent diuretics, patients receiving Diulo are not "wrung out" in two or three hours.

Although the conditions of some patients can be adequately controlled with a 5-mg dose of Diulo, one 10-mg tablet daily can provide effective diuresis around the clock in your patients with CHF, including those with paroxysmal nocturnal dyspnea.

DIULO™ (metolazone) 2½-mg., 5-mg. and 10-mg. tablets *Before prescribing, see complete prescribing information. The following is a brief summary:* ***Indications:*** *Diulo (metolazone) is an antihypertensive diuretic indicated for the management of mild to moderate essential hypertension as sole therapeutic agent and in the more severe forms of hypertension in conjunction with other antihypertensive agents. Also, edema associated with heart failure and renal disease.* ***Contraindications:*** *Anuria, hepatic coma or precoma; allergy or sensitivity to metolazone.* ***Warnings:*** *In theory, cross-allergy may occur in patients allergic to sulfonamide-derived drugs, thiazides or quinethazone. Hypokalemia may occur, and is a particular hazard in digitalized patients; dangerous or fatal arrhythmias may occur. Azotemia and hyperuricemia may be noted or precipitated. Considerable potentiation may occur when given concurrently with furosemide. When added to other antihypertensives, the dosage of the other agents should be reduced. Use with potassium-sparing diuretics may cause potassium retention and hyperkalemia. Administration to pregnant women or those of childbearing age requires that potential benefits be weighed against possible hazards to the fetus. Metolazone appears in the breast milk. Not recommended for pediatric use.* ***Precautions:*** *Perform periodic examination of serum electrolytes, BUN, uric acid, and glucose. Observe patients for signs of fluid or electrolyte imbalance, hyponatremia, hypochloremic alkalosis and hypokalemia. These determinations are particularly important when there is excessive vomiting or diarrhea, or when parenteral fluids are administered. Patients treated with diuretics or corticosteroids are susceptible to potassium depletion. Caution should be observed when administering to patients with gout or hyperuricemia or those with severely impaired renal function. Insulin requirements may be affected in diabetics, and hyperglycemia and glycosuria may occur in latent diabetes. Chloride deficit and hypochloremic alkalosis may occur. Orthostatic hypotension may occur. Dilutional hyponatremia may occur.* ***Adverse Reactions:*** *Constipation, nausea, vomiting, anorexia, diarrhea, bloating, epigastric distress, intrahepatic cholestatic jaundice, hepatitis, syncope, dizziness, drowsiness, vertigo, headache, orthostatic hypotension, excessive volume depletion, hemoconcentration, venous thrombosis, palpitation, chest pain, leukopenia, urticaria, other skin rashes, dryness of mouth, hypokalemia, hyponatremia, hypochloremia, hypochloremic alkalosis, hyperuricemia, hyperglycemia, glycosuria, raised BUN or creatinine, fatigue, muscle cramps or spasm, weakness, restlessness, chills, and acute gouty attacks.* ***Usual Initial Once-Daily Dosages:*** *Mild to moderate essential hypertension – 2½ to 5 mg.; edema of cardiac failure – 5 to 10 mg.; edema of renal disease – 5 to 20 mg. Dosage adjustment is usually necessary during the course of therapy.* ***How Supplied:*** *Tablets, 2½, 5 and 10 mg.; in bottles of 100 and 500, and cartons of 100 unit-dose individually blister-sealed tablets.*

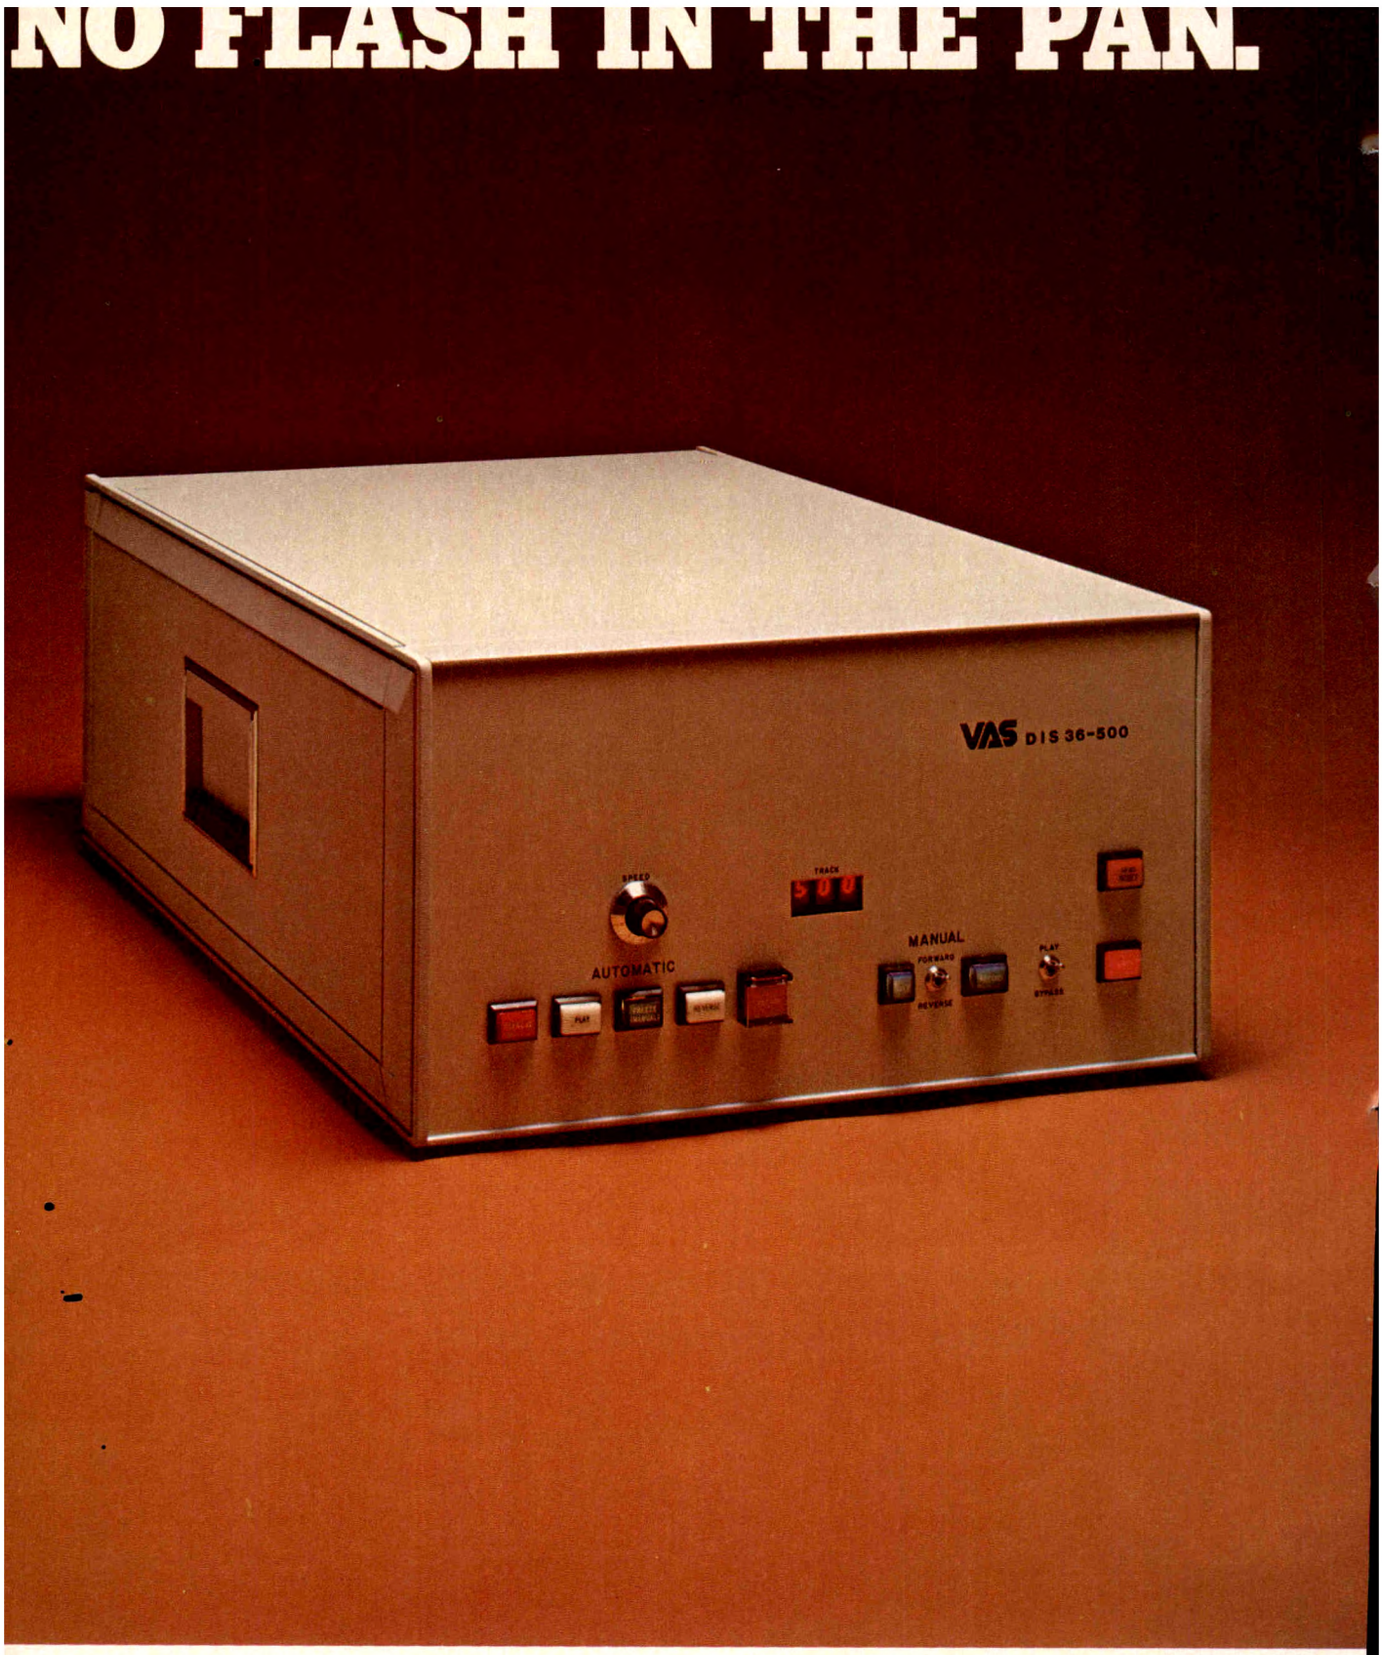
NO FLASH IN THE PAN.



BIOFEEDBACK BIOFEEDBA

The VAS Dynamic Image Store® (DIS) Video Disc Recording System records each sequential flashing image during a spot filming series and then replays that image until the next exposure is made. It's like viewing continuous flouroscopy —without the continuous radiation. So now you can follow the progression of the contrast bolus while panning—without the flashing—without waiting for the film to be developed before you determine the next injection.

Optimally, the DIS reduces radiation dosage by lowering exposure time and letting you replay any sequence over and over again with no image degradation. Instantly and flicker free. It achieves this with Cine Lock, which records the cine run on the disc for instant replay in variable slow motion (6-60 images per second), real-time, or frame freeze that lets you advance the image frame by frame for an analysis of the injection; Photo Spot, which fills in between the flash and plays back the film; and Pulsed Flouroscopy for dose reduction during catheter manipulation.

Ask your system's manufacturer or local sales representative about us. In addition to angiographic and heart catheterization applications, we have a full line of Video Disc Recording Systems that provide instant image replay in Ultrasound and Mobile C-arm, as well as dose reduction in x-ray applications. Then call us at (213) 320-8334. Or write VAS Corporation, 2525 Maricopa Street, Torrance, California 90503. We'll show you how our DIS Video Disc Recording System not only reduces your chances of missing what you wanted on film, but also reduces your patient's radiation dosage.

Pfizer Laboratories
invites you to attend
an Educational Symposium:*

Nifedipine in Ischemic Heart Disease: The International Experience

Chairman:
Dennis Krikler, M.D., F.A.C.C.
Consultant Cardiologist
Royal Postgraduate Medical School
Hammersmith Hospital, London, England

The symposium immediately follows the 30th Annual Scientific Session of the American College of Cardiology and will be held in:

The Imperial Ballroom of
The San Francisco Hilton Hotel
333 O'Farrell St., San Francisco, California

March 19, 1981
1:30-5:30 P.M.

If you would like to attend the symposium and have not yet registered, please do so at the Pfizer booths #2004, 2005 and 1101 at Brooks Hall during the American College of Cardiology Session.

*Science & Medicine is assisting in the organization of the symposium under an educational grant from Pfizer Laboratories.

Nifedipine in the Management of Ischemic Heart Disease: The European Experience

MODERATOR: **Eugene Braunwald, M.D., F.A.C.C.**
Hersey Professor of the Theory and Practice of Medicine
Harvard Medical School

TOPICS:

Echocardiographic Mimicry of Pericardial Effusion

PATRICIA C. COME, MD*
MARILYN F. RILEY*
NICHOLAS J. FORTUIN, MD†

Boston, Massachusetts
Baltimore, Maryland

Echocardiography is a sensitive technique for the detection of pericardial effusion, but the abnormal echocardiographic patterns seen with effusions are not, however, entirely specific for that diagnosis. This study describes four patients in whom anatomic structures, a coronary artery to coronary sinus fistula (one case) and tumors metastatic to pericardium (three cases), produced posterior and, in two cases, anterior spaces compatible with pericardial fluid. Echocardiographic patterns mimicking pericardial effusion have previously been reported in patients with anatomic abnormalities such as mitral anular calcification, pleural effusions, left atrial enlargement, anterior mediastinal or pericardial tumors, foramen of Morgagni hernia and pseudoaneurysm of the left ventricle. It appears that structures of fluid or tissue density, interposed between the heart and the airfilled lung, can produce echocardiographic patterns simulating pericardial effusion.

Since pericardial effusion was first recognized by ultrasonic techniques in 1955,[1] echocardiography has become the primary means of detecting the presence of pericardial effusion.[2] The technique is sensitive, capable of detecting abnormal patterns of pericardial movement and of epicardial-pericardial separation associated with even minimal effusions.[3] However, the abnormal echocardiographic pattern of a space behind the left ventricular posterior wall or anterior to the right ventricular wall is not entirely specific for the diagnosis of pericardial effusion. Improper technique and intracardiac and extracardiac anatomic abnormalities may produce abnormal echocardiographic patterns that mimic the echocardiographic appearance of pericardial fluid.[2–19]

We describe here four patients in whom anatomic structures located anteriorly and posteriorly relative to the heart produced spaces compatible with pericardial effusion. In the first case, the echocardiographic free space was produced by a large circumflex coronary arterial aneurysm or coronary artery to coronary sinus fistula. In the other three patients, the spaces were produced by metastatic tumors.

Methods

The M mode echocardiographic examinations were performed according to standard technique using a Smith Kline Ekoline 20 A ultrasonoscope, an Irex 101 ultrasonoscope or an Irex System II ultrasonoscope and a 0.5 inch (1.27 cm) diameter, 2.25 megahertz transducer focused at 7.5 cm. The studies were recorded on a Cambridge strip chart recorder, a Honeywell direct writing recorder or an Irex recorder. The two dimensional echocardiographic scans were obtained in several planes using an 80° Varian, model 3000, sector scanner.

Case Reports

Case 1

A 67 year old woman with a history of rheumatic fever at age 17 was admitted to the Beth Israel Hospital to evaluate a 10 to 12 year history of fatigue, exertional dyspnea and epigastric tightness. A murmur had been noted for 50 years. Medications included digoxin and furosemide.

The pulse rate was 72/min and regular and the blood pressure was 125/55 mm Hg. There was no jugular venous distension. Examination of the lungs was normal. There was a right ventricular heave, and a vigorous left ventricular

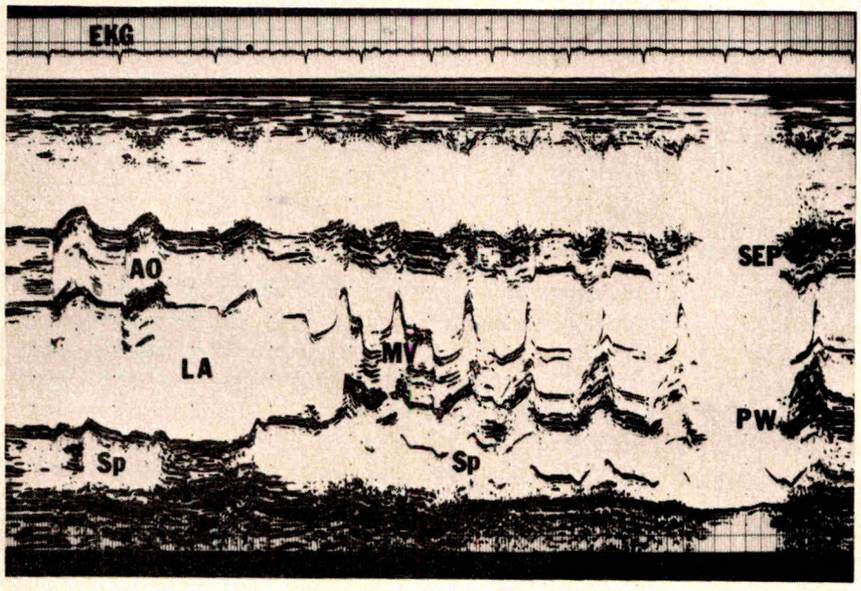

FIGURE 1. Case 1. M mode echocardiographic scan from the aortic root (AO) and left atrium (LA) to the left ventricular apex. Echo-free spaces (Sp) are seen posterior to the left atrium and to the left ventricular posterior wall (PW). EKG = electrocardiogram; MV = mitral valve; SEP = septum.

impulse was palpable in the fifth to sixth intercostal space 2 cm to the left of the mid clavicular line. A grade 2/6 holosystolic murmur was heard at the apex and radiated to the axilla. A continuous murmur was heard over the left lower thorax posteriorly. The electrocardiogram revealed atrial fibrillation and left ventricular hypertrophy and S-T and T wave changes. The chest X-ray film revealed upper zone redistribution and an enlarged heart with apparent right ventricular and left atrial enlargement. No pleural effusion was present.

An echocardiogram (*Fig. 1*) revealed enlargement of the right ventricle and left atrium and a left ventricular diastolic dimension of 5.4 cm. The mitral and aortic valves appeared normal. An echo-free space, measuring in some areas 2 to 2.5 cm, was seen in the area of the atrioventricular (A-V) groove and disappeared with scanning toward the aortic root and left atrium. With damping, all intracardiac echoes disappeared, the only remaining echo being that distal to the space.

At cardiac catheterization, an oxygen content step-up found in the right atrium suggested a left to right shunt. Calculated pulmonary to systemic blood flow ratio was 2.4:1. Aortic root injection (Fig. 2, left) and left coronary angiography revealed a large, long main left coronary artery. There was a very large aneurysm in the proximal left circumflex coronary artery. The remainder of the left circumflex artery was dilated and tortuous and appeared to empty into a dilated coronary sinus. Axial left anterior oblique views obtained following injection of contrast medium into the aortic root and right anterior oblique views obtained during left ventriculography (Fig. 2, right) demonstrated that the descending thoracic aorta was separated from both the left atrium and the left ventricle by the huge coronary arteriovenous fistula and dilated coronary sinus.

At cardiac surgery, there was no evident pericardial effusion. The angiographic findings were confirmed. The distal

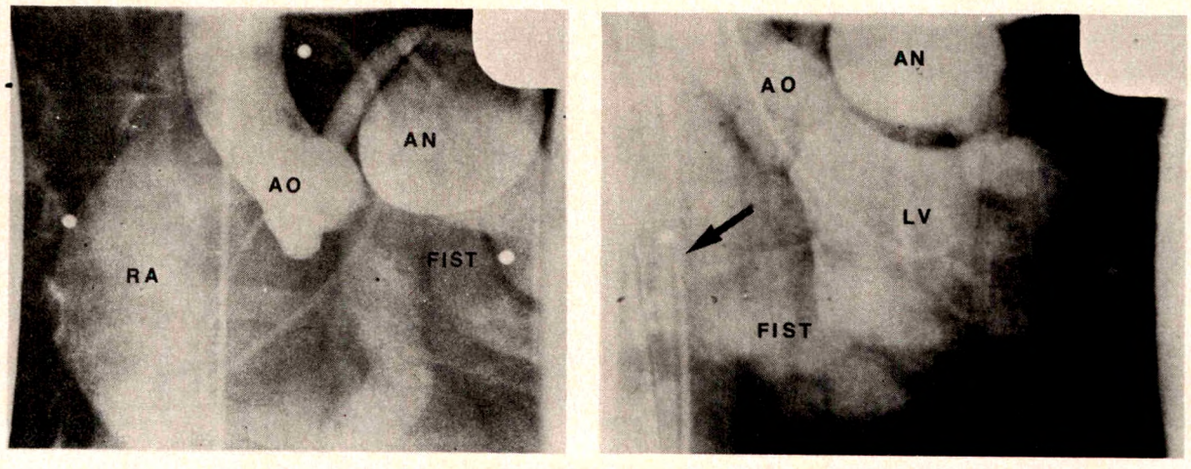

FIGURE 2. Case 1. **Left,** aortic root (AO) injection in the right anterior oblique projection demonstrates a large aneurysm (AN) of the proximal circumflex coronary artery and the coronary artery to coronary sinus fistula (FIST). The right atrium (RA) is seen to fill from the left to right shunt. **Right,** left ventriculogram in the right anterior oblique projection demonstrates the aneurysm (AN) of the left circumflex coronary artery and the large coronary arteriovenous fistula (FIST), which empties into the coronary sinus. The **arrow** points to the location of the angiographic catheter in the descending aorta. The fistula is seen to separate the left ventricle (LV) from the descending thoracic aorta. AO = ascending aorta; LV = left ventricle.

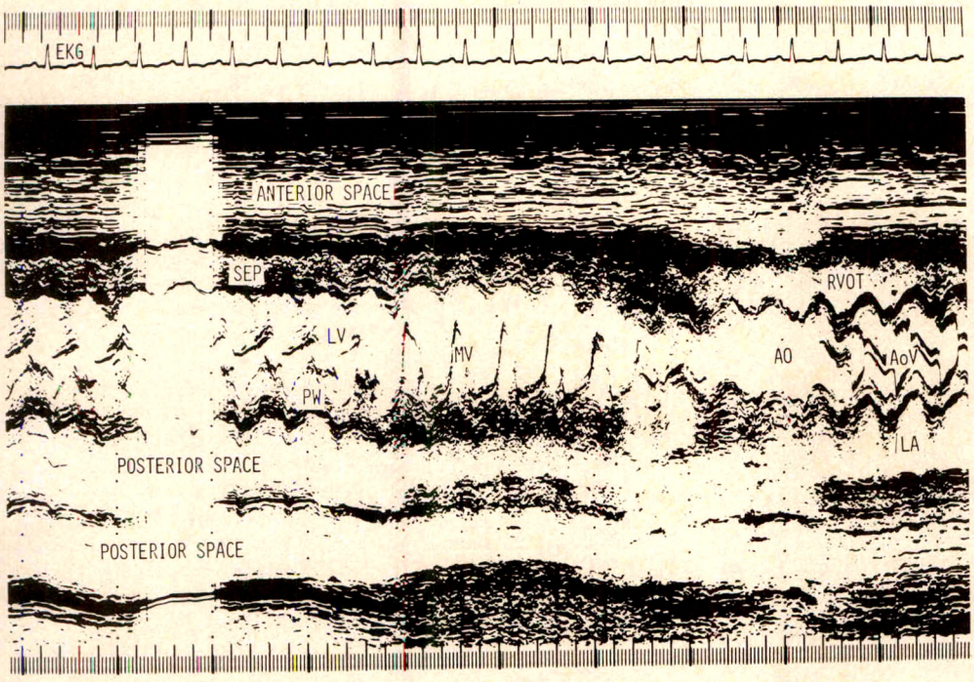

FIGURE 3. Case 2. M mode echocardiographic scan from the left ventricle (LV) to the aortic root (AO) and left atrium (LA). An anterior echo-filled space and two posterior echo-free spaces, all confirmed at autopsy to represent pleural and pericardial infiltration by lymphoma, are visualized. The tumor appeared to compress the right ventricular cavity between the right ventricular wall and septum (SEP). AoV = aortic valve; EKG = electrocardiogram; MV = mitral valve; PW = posterior wall; RVOT = right ventricular outflow tract.

end of the circumflex coronary artery at the site of its anastomosis with the coronary sinus was ligated.

Case 2

A 62 year old man was admitted to the Beth Israel Hospital with increasing dyspnea. After a diagnosis of stage IVB poorly differentiated lymphocytic lymphoma 17 months previously, the patient had received chemotherapy and radiotherapy, including mediastinal and later total body irradiation. Three months before admission, he had undergone chest tube drainage of a left pleural effusion and instillation of tetracycline to sclerose the pleura.

His pulse was 110/min and regular and his blood pressure was 125/60 mm Hg with a 35 mm Hg pulsus paradoxus. His respirations were 27/min and labored. The jugular veins were distended to the angle of the jaw with the patient sitting. Basilar dullness and decreased breath sounds, rales in the mid lung fields and diffuse wheezing were present. The heart sounds were faint and a pericardial friction rub was noted. The liver and peripheral lymph nodes were enlarged. Chest X-ray film revealed hilar lymphadenopathy. The heart appeared enlarged and the epicardial fat pad was seen to lie several centimeters within the anterior heart border on the lateral film. A left pleural effusion was noted on decubitus films and the upper zone pulmonary vessels were distended, suggesting left heart failure.

An echocardiogram was obtained to evaluate the possibility of pericardial tamponade. On M mode echocardiographic study (Fig. 3) an echo-filled anterior space was visualized between the chest wall and the right ventricular wall. Two echo-free spaces were visualized posterior to the left ventricular wall. One appeared to disappear behind the left atrium. There was no swinging movement to the heart. The aortic valve ejection time decreased appreciably during inspiration. Two dimensional echocardiography, including views obtained with long and short axis as well as apical scanning (Fig. 4), demonstrated echo-free spaces surrounding the anterior, apical and posterior parts of the heart. The possibility of a large pericardial effusion could not be excluded, but echocardiographic abnormalities due to pleural effusion and tumor encasement of the heart were considered equally likely. The patient died the following day.

At autopsy, lymphoma was found throughout the body. Lymphomatous infiltration of the pleura on the left resulted in a 1 to 3 cm thick mass in continuity with the mediastinal and hilar lymph nodes. The heart was entirely encased by a 3 to 4 cm thick shell of lymphoma (Fig. 5). Only 150 cc of left pleural fluid and 20 cc of pericardial fluid was found.

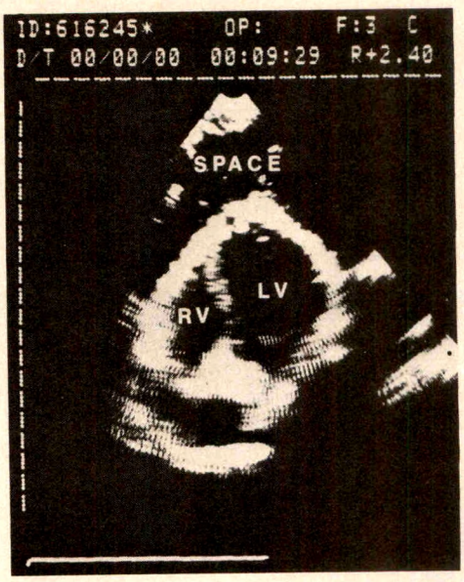

FIGURE 4. Case 2. Two dimensional echocardiogram with the transducer placed at the apex demonstrates a large echo-free space separating the chest wall from the left (LV) and right (RV) ventricular walls. The space appears to surround the base as well as the apex of the heart.

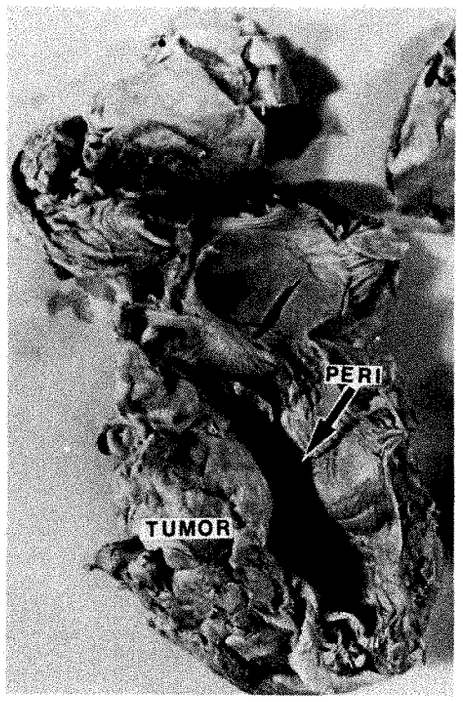

FIGURE 5. Case 2. Autopsy specimen showing the thick tumor surrounding the entire parietal pericardium (**arrow**). The heart has been removed from the pericardial cavity.

Case 3

A 91 year old woman admitted to the Johns Hopkins Hospital for evaluation of lethargy underwent echocardiographic examination to determine the origin of a systolic ejection murmur. The echocardiogram revealed severe thickening and probably calcification of the aortic valve leaflets. However, when best seen, systolic aortic leaflet excursion was maintained, with a maximal cusp separation of 1.6 cm. The pericardial echo was flattened and very minimally separated from the epicardial echo in systole and diastole, suggesting a minimal posterior effusion. With scanning from the apex to the aortic root and left atrium, a 2.3 cm echo-free space was apparent behind the posterior left ventricular wall, in the region of the junction of the left ventricle and left atrium (Fig. 6). The echo-free space disappeared with scanning toward the apex as well as toward the base of the heart. A diagnosis of probable loculated pericardial effusion or pleural effusion was suggested. The patient died unexpectedly.

At autopsy, a squamous cell carcinoma was found to have infiltrated the right middle and right upper lobes of the lung, the diaphragm and the right pulmonary artery. Metastases were found in the lungs, hilar lymph nodes, right and left atria, diaphragm and kidneys. A large, homogeneous-appearing tumor nodule was located on the posterior wall of the heart at the junction of the left ventricle and left atrium.

Case 4

A 65 year old woman who had undergone left pneumonectomy and chemotherapy 1 year previously for oat cell carcinoma metastatic to regional lymph nodes and pleura was admitted to the Beth Israel Hospital with increasing shortness of breath, peripheral edema and ascites. The pulse was 110/min, the blood pressure 110/70 mm Hg and the respiratory rate 30/min. The jugular veins were elevated to the angle of the mandible with the patient sitting. Examination of the lungs revealed basilar dullness and decreased breath sounds. The heart sounds were unremarkable. Ascites and gross peripheral edema were noted. Low voltage was present on the electrocardiogram. A chest X-ray film revealed a moderate-sized right pleural effusion, right lower lobe consolidation and evidence for previous left pneumonectomy.

The echocardiogram was technically difficult to perform, probably because of the mediastinal shift resulting from the prior pneumonectomy. However, definite spaces were detected between the chest wall and the right ventricular wall and between the posterior left ventricular wall and the presumed posterior pericardium (Fig. 7). The differential diagnosis was considered to include both pericardial effusion and tumor metastasis to the pericardium.

The patient had progressively increasing shortness of breath, tachycardia and hypotension. She was judged not to be a candidate for further chemotherapy and died.

Autopsy revealed oat cell carcinoma involving the entire left thoracic cavity. One to two cm thick tumor encased the heart. Seventy-five cc of fluid was present within the pericardial cavity.

Discussion

The pericardial space separating the epicardium and the parietal pericardium normally contains only a very

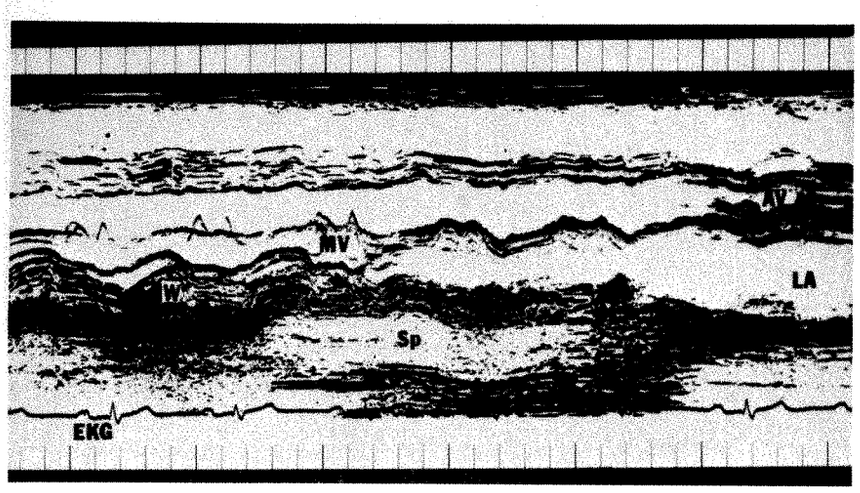

FIGURE 6. Case 3. M mode echocardiographic scan from the left ventricle to the aortic root and left atrium (LA). An echo-free space (Sp) is seen below the posterior left ventricular wall (W), near its junction with the left atrium. AV = aortic valve; EKG = electrocardiogram; MV = mitral valve.

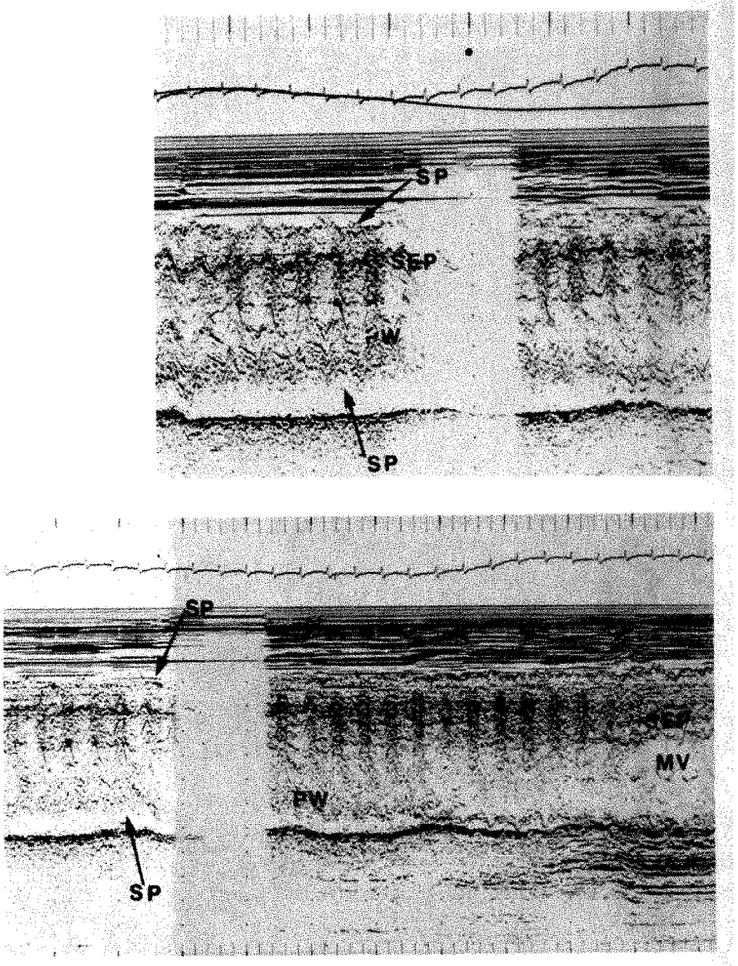

FIGURE 7. Case 4. **Top,** the left ventricular echogram was technically difficult to obtain in this patient because of her prior pneumonectomy. However, in the left ventricular area an anterior echo-free space (SP) and a posterior space (SP), measuring up to 2.3 cm, were visualized, suggesting a sizable pericardial effusion. The most intense distal echo, which could easily be mistaken for pericardium, was nonmoving. **Bottom,** M mode echocardiographic scan from the left ventricle to the mitral valve (MV) again demonstrates anterior and posterior spaces (SP) easily mistaken for a moderately large pericardial effusion. The heater element in the recorder has caused the differences in paper color. PW = posterior wall; SEP = septum.

small amount of fluid.[2,20–22] Echocardiographically, the pericardium can normally be recognized as the structure immediately adjacent to and moving in concert with the outer surface of the ventricular wall.[2,3] It is normally the strongest reflector of ultrasound in the heart because it serves as a specular reflector and because it separates heart muscle from the air-filled lung, which has an acoustic impedance only a fraction of that of other body tissues,[23] including the heart. Therefore, when the amount of energy emanating from the echocardiographic transducer is decreased, with use of a technique known as damping, the posterior pericardial echo is usually identified as the last remaining echo.

Echocardiographic signs of pericardial effusion: A pericardial effusion represents accumulation of excess fluid between the epicardium and pericardium. Because the pericardium remains a specular reflector and continues to separate the air-filled lung from a medium, now fluid, with a higher acoustic impedance, it will still be identifiable echocardiographically as the strongest reflecting surface. However, a space, usually echo-free but occasionally echo-filled, will now be seen between pericardium and epicardium.[2,3] This space typically disappears behind the left atrium because of the tight reflection there of the pericardium onto the pulmonary veins.[2,9,20–22] Occasionally, in the case of a large effusion or one under increased pressure, pericardial fluid may be seen behind the left atrium.[2,8,9] If an effusion is very small, the pericardial echo may retain some movement.[3] However, as the size of the effusion increases, the pericardium becomes insulated from the movement of the epicardium, causing the pericardial echo to become nonmoving,[2,3] and an anterior echo-free space may develop.

Simulators of pericardial effusion: In the four patients presented, spaces were visualized echocardiographically between the left ventricular epicardium and the strongest reflecting surface distal to the heart, suggesting pericardial effusions. However, no effusion was detected at surgery in the first patient and only 20, 36 and 75 cc, respectively, of pericardial fluid was found at autopsy in the others. The large echo-free spaces seen on ultrasonic examination were almost certainly produced by the large coronary artery to coronary sinus fistula or coronary aneurysm in Case 1 and by the pericardial metastases in the other three cases. The posterior margins of the fistula and of the tumors were likely the most intense echo-producing interfaces because, lying posterior to the cardiac wall, they separated the air-filled lung from soft tissue. The echo-free space in Case 3 simulated a loculated pericardial effusion because it was limited to the level of the tumor and the pericardium appeared normal above and below this level. Occasionally the posterior thoracic aorta may be

visualized as an echo-free space posterior to the heart. This possible cause of the echo-free space was excluded in Patient 1 by cineangiography (Fig. 2B). Lymphoma and carcinoma separated the heart from the descending thoracic aorta in Patients 2 and 4. Visualization of the aorta posterior to the A-V groove cannot be definitely excluded as the reason for the posterior echo-free space in the third patient. However, the discovery of a large metastatic carcinoma nodule in an anatomic position corresponding to the echo-free space seen on ultrasonic examination strongly suggests that the echo-free space was, in fact, produced by the tumor nodule. It should be noted that tumor encasement of the heart, as in our Case 2, may result in clinical and echocardiographic findings that resemble those observed in pericardial tamponade.

Other conditions mimicking pericardial effusion: Other unusual pathologic conditions previously reported to produce echocardiographic patterns compatible with pericardial effusion include a markedly dilated left atrium,[10] a foramen of Morgagni hernia,[11] a large retrosternal lymphoma,[2] left ventricular pseudoaneurysms[12–15] and a tumor involving the pericardium that resulted in an echo-filled space between the left ventricular posterior wall and the distal pericardial echo.[24] Mitral anular calcification[6,7] and pleural effusions[8,9] have been recognized as more common anatomic abnormalities capable of producing echocardiographic patterns that could be misinterpreted as representing pericardial effusions. In addition, it is recognized that normal anatomic structures such as the left inferior pulmonary vein,[16] the descending thoracic aorta and the coronary sinus,[17–19] especially when dilated, may produce echo-free spaces posterior to the heart.

Differential diagnosis: Echocardiography is a sensitive technique for the identification of pericardial fluid[3] and has become the foremost tool for evaluating patients with suspected effusion. Because an improper diagnosis of pericardial effusion may result in unwarranted pericardiocentesis or more aggressive surgical procedures, appropriate attention must be paid to recognition of technical artifacts and to consideration of other anatomic conditions that may simulate pericardial effusion. Slow scanning from the apex to the base of the heart will allow visualization of the location of the echo-free space relative to the left ventricular and left atrial walls and allow assessment of left atrial wall movement. Such scanning may permit differentiation of pericardial fluid from other common anatomic abnormalities such as pleural effusion and mitral anular calcification. The presence of a somewhat atypical echocardiographic pattern of pericardial effusion, such as apparent loculation of fluid or the absence of an anterior echo-free space in a patient with an apparent large posterior pericardial effusion, should raise the possibility of a false positive diagnosis. Such a diagnosis might be caused by the presence of a vascular structure or solid mass adjacent to the posterior left ventricular wall. Two dimensional echocardiography, which permits visualization of anatomic structures in two distance dimensions, is becoming increasingly available and may also facilitate differential diagnosis.

"Supernormal" Phase of Atrioventricular Conduction With Concealed Capture Beats

Significance of Odd Numbers of P Waves Between Capture Beats

ALAN LINDSAY, MD*
LEO SCHAMROTH, MD, DSc, FACC†

Salt Lake City, Utah
Johannesburg, South Africa

In 1968 Moe and associates postulated multilevel atrioventricular (A-V) block as a mechanism for some forms of the supernormal phase of A-V conduction. In 1971 Schamroth further postulated that, if this were correct, there would only be odd numbers of sinus P waves between the capturing impulses. This report presents two cases of sinus rhythm dissociated from idionodal escape rhythm as a result of high grade A-V block. The rhythm is complicated by manifest and concealed A-V captures during the so-called supernormal phase. There are only odd numbers of P waves between the capturing impulses.

The "supernormal" phase of atrioventricular (A-V) conduction is an apparent paradoxical electrocardiographic manifestation wherein relatively early supraventricular impulses, which should encounter more refractoriness, are conducted through the A-V node to the ventricles, and where relatively late supraventricular impulses, which should encounter less refractoriness, are blocked. Many of these so-called paradoxical manifestations of the "supernormal" phase of A-V conduction have been examined in elegant studies[1] and are subject to logical electrocardiographic deduction. The following two cases are of special interest because they reflect, for the first time, concealed supernormal A-V nodal penetration and also provide confirmatory evidence of a mathematical hypothesis that was propounded to explain this particular manifestation of A-V nodal supernormality.[2]

Case Reports

Case 1

The electrocardiogram (Fig. 1, a continuous strip of lead V_1, and Fig. 2, a later strip of the same lead, diagrammed) was recorded from an elderly man with a 1 week history of weakness. He was taking no medications.

The electrocardiogram in Figure 1 shows a basic normal sinus rhythm. The P-P intervals measure 0.84 second, representing a sinus rate of 71/min. Most of these sinus P waves are dissociated from an A-V junctional escape rhythm with an R-R interval of 1.52 seconds, representing a heart rate of 39 beats/min. This basic manifestation is reflected by the first two QRS complexes and the first four P waves in the top strip. This dissociation between a faster sinus rhythm and a slower A-V nodal escape rhythm represents high degree A-V block. Some of the ensuing sinus impulses that occur very early in the R-R interval and others that are so early that they actually precede the R wave (of the R-R interval containing the capture [see later]) and thus occur very late in the preceding R-R interval are conducted.

Conduction may take one of the following forms: (a) through the A-V node without reaching the ventricles; (b) through the A-V node and with normal intraventricular conduction; and (c) through the A-V node and with aberrant ventricular conduction resulting in a left or a right bundle branch block pattern. These sinus impulses are labeled with numbered arrowheads in Figure 1. Impulses 3 and 5 are conducted normally to the ventricles resulting in capture beats

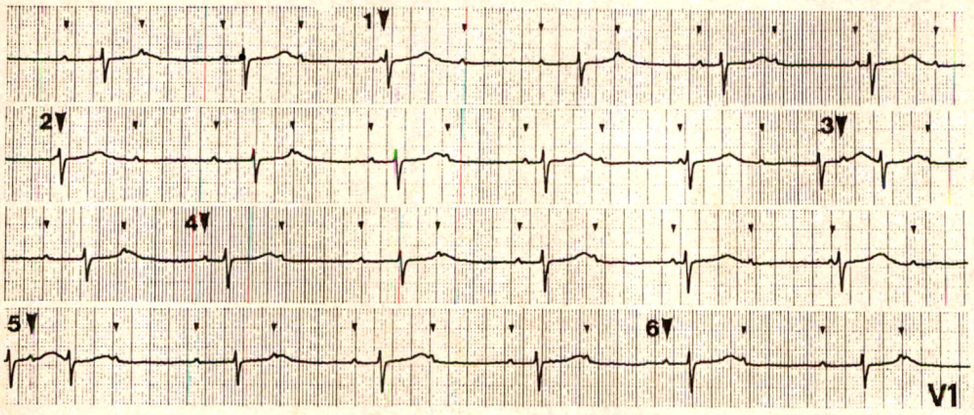

FIGURE 1. Case 1. Electrocardiogram (a continuous strip of lead V_1) showing manifest and concealed 'supernormal' captures with only odd numbers of intervening P waves. **Arrows** reflect the capturing impulses.

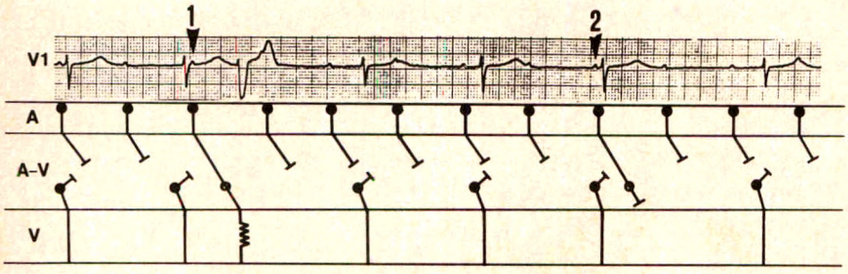

FIGURE 2. Case 1. A later diagrammed section of lead V_1. **Arrows** reflect the capturing impulses.

with a normal QRS complex (form b). The first capturing impulse in Figure 2 is conducted with a left bundle branch block pattern (form c). Other capturing impulses (1, 2, 4, 6 in Fig. 1 and the second capturing impulse in Fig. 2) reflect concealed A-V nodal conduction (form a). This is evidenced by the resetting of the A-V nodal cycle due to the premature discharge of the A-V nodal pacemaker by the concealed A-V nodal penetration of the supraventricular impulse. The postponed A-V nodal cycle results in a relatively long R-R interval. These intervals range from 1.82 to 2.08 seconds.

The relation to the near synchronous QRS complex of the sinus impulses resulting in concealed conduction, aberrant ventricular conduction and normal intraventricular conduction is depicted in Figure 3. P waves that occur relatively late after the R wave are associated with normal intraventricular conduction (open circles in Fig. 3). P waves that occur relatively early after the R waves are associated with right or left bundle branch block (cross in Fig. 3). P waves that occur synchronously with or before the R wave are associated with concealed conduction (black dots in Fig. 3). There were three instances of concealed conduction with P waves that overlapped with, or occurred later than, the period of bundle branch block conduction. These probably reflect a critical state of bundle branch refractoriness. It is also noteworthy that a sinus impulse that occurs 280 ms before the QRS complex can capture the A-V nodal pacemaker after the manifest discharge, as represented by the QRS complex, and reset the ensuing A-V nodal cycle. This reflects an exceptionally long partial refractory period in the upper part of the A-V node.

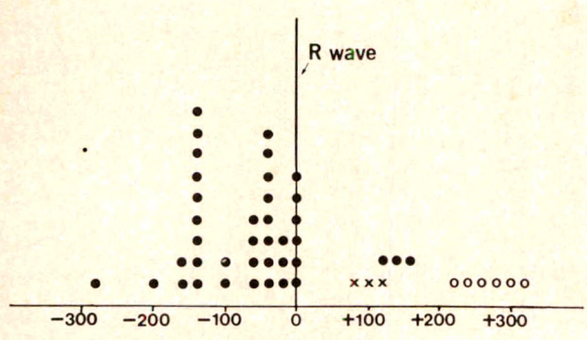

FIGURE 3. Case 1. Diagram illustrating the P to R or R to P relationship of capturing sinus impulses. The **closed circles** or **dots** represent concealed conduction. The **crosses** represent conduction with bundle branch block. The **open circles** represent capture with normal intraventricular conduction. Figures represent milliseconds.

The P waves between the sinus impulses that penetrate into the A-V node or are conducted to the ventricles occur in odd numbers only. Thus, between the various arrows in Figure 1 are seven, nine, three, nine and seven P waves, respectively; and there are five P waves between the capturing impulses in Figure 2. Forty-seven intervals between capture beats were observed and, with one exception, the P waves in these intervals occurred in odd numbers. The exception was an interval with two intervening sinus P waves.

Case 2

The electrocardiogram (Fig. 4, a continuous strip of lead V_1) was recorded from a 77 year old man who went into a coma 2 days before the insertion of a pacemaker; the tracing was recorded at a later date when the pacemaker failed. The small ineffective pacing spike artifacts are evident throughout the tracing. The P-P intervals of the basic sinus rhythm measure 0.79 second, representing a heart rate of 76 beats/min. The sinus rhythm is dissociated from an A-V junctional escape rhythm as represented by the narrow and normal QRS complexes. The R-R intervals measure 1.42 seconds, representing

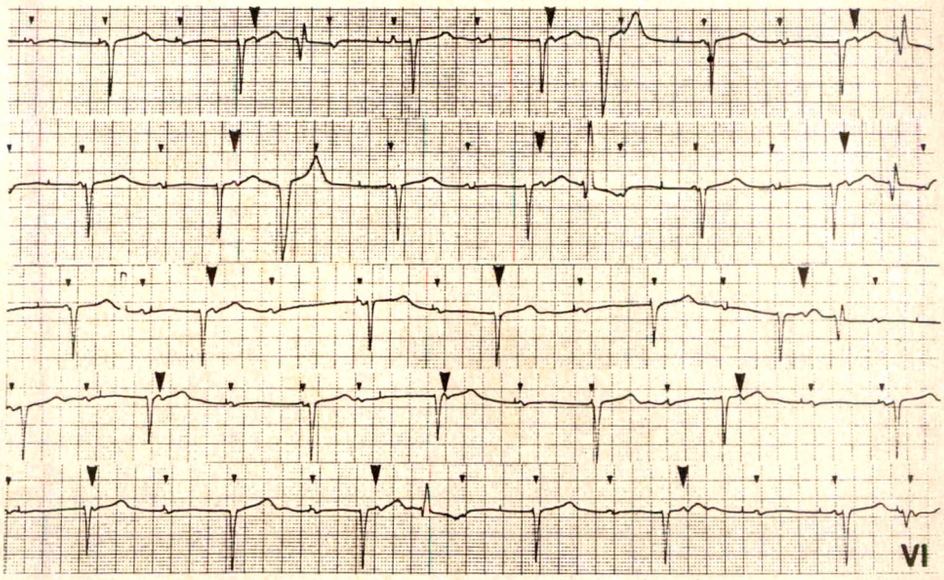

FIGURE 4. Case 2. Electrocardiogram (a continuous strip of lead V_1) showing manifest and concealed 'supernormal' captures with only odd numbers of intervening P waves. **Arrows** reflect the capturing impulses.

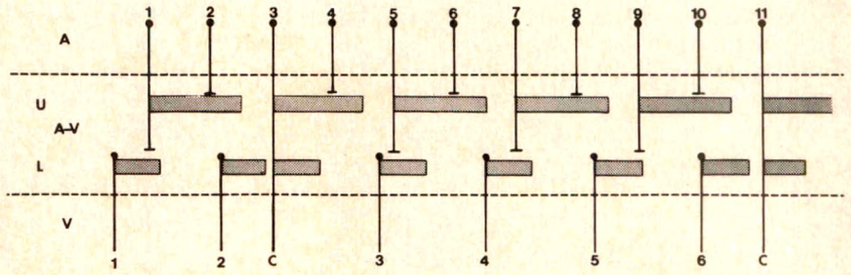

FIGURE 5. Diagram illustrating the effect of differential horizontal A-V junctional refractoriness. There is 2:1 A-V block in the upper part of the A-V node (U) with 1:1 conduction in the lower part of the A-V node (L).

a heart rate of 42 beats/min. This dissociation between a faster sinus rhythm and a slower A-V junctional escape rhythm reflects the presence of high grade A-V block. Sinus impulses that occur very early in the cycle (labeled with a large arrowhead) are conducted. These represent the "supernormal" phase of A-V conduction because later impulses are blocked.

The conduction takes one of the following forms: (1) Conduction to the ventricles with right bundle branch block. This pattern is represented by the first and last captures in the top strip (Fig. 4). (2) Conduction to the ventricles with left bundle branch block. This pattern is represented by the second capture beat in the top strip and the first capture beat in the second strip. (3) Concealed A-V nodal conduction. This pattern is reflected by resetting of the A-V nodal cycle by the sinus impulse that penetrates into the A-V node to discharge the A-V junctional pacemaker but fails to reach the ventricle. It is represented by the long cycles in the third and bottom strips, which reflect concealed supernormal capture beats.

The sinus impulses intervening between the capture beats (labeled with the small arrowheads) occurred, as in Case 1, in odd numbers only. Seventy-six such intervals were analyzed and these contained only odd numbers of P waves (Table I).

Discussion

Mechanisms of supernormal phase of A-V conduction: Several hypotheses have been put forward to explain the supernormal phase of A-V conduction. For example, phase 4 A-V block may explain the block of late impulses and the conduction of relatively early impulses. Another possible mechanism (based on the work of Moe et al.[1]) is the assumption of differential "horizontal" refractoriness within the A-V node (Fig. 5). The refractory period of the upper part of the A-V node (U) is longer than the refractory period of the lower part of the A-V node (L). This results in a 2:1 A-V block in the upper part of the node, and 1:1 conduction in the lower part. The 2:1 A-V block increases the effective sinus cycle at the level of the lower A-V node; that is, the conducted sinus cycle at this level is, in effect, twice the normal sinus cycle. This is represented, for example, by the interval between sinus impulses 1 and 3. This in-

TABLE I

Case 2. Analysis of Numbers of P Waves Between the Capture Impulses

P Waves (n)	Measurements (n)

Total	76

crease in the effective conducted sinus cycle permits the escape of a subsidiary A-V nodal pacemaker situated in the lower part of the A-V node.

Although the A-V junctional cycle (represented by A-V nodal impulses 1 and 2, Fig. 5) is longer than the true sinus cycle, it is shorter than the effective conducted sinus cycle. The A-V nodal rhythm thus escapes through default of the sinus impulse as a result of the 2:1 A-V block. Interference dissociation now ensues between (1) the sinus impulses represented by the effective conducted sinus cycle, and (2) the A-V nodal impulses. The A-V dissociation is complicated by occasional ventricular capture beats (labeled C) (the momentary conduction of the sinus impulse to, and capture of, the ventricles). This creates the illusion of a paradoxical situation. The P wave representing the conducted impulse occurs at a relatively short R-P interval after the preceding A-V junctional beat—represented by the interval between A-V nodal beat 2 and the ensuing capture beat (interval 2-C). Interval 6-C is an analogous situation. P waves that occur at longer R-P intervals are "paradoxically" not conducted; for example, sinus impulse 8 occurs at a long R-P interval after A-V nodal impulse 4 and yet is blocked. The capture beats are thus conducted in an early critical phase of the lower cycle.

Hypothesis of only odd numbers of intervening P waves: When this particular form of interference dissociation occurs, namely, 2:1 A-V block in the upper A-V node associated with 1:1 conduction in the lower A-V node, only odd numbers of P waves can occur between the intervening capture beats. This is because only the odd-numbered impulses can penetrate the upper part of the A-V node. Their conduction through the lower part of the A-V node will depend on the state of responsiveness resulting from the A-V junctional escape rhythm. For example, in Figure 3 there are only seven P waves (numbered 4 to 10) between the two capture beats.

This theoretical mathematical manifestation of the hypothesis of Moe et al.[1] was first propounded by Schamroth[2] in 1971, and there can be no doubt from the many observations in these two cases that the hypothesis of only odd numbers of intervening P waves holds. This mathematical manifestation thus confirms the original hypothesis proposed by Moe et al.[1] in 1968. This case is thus of particular interest because the phenomenon of concealed supernormal A-V captures has not previously been described, and the mathematical hypothesis of the intervening odd numbers of sinus beats to confirm the hypothesis of differential horizontal refractoriness is now clearly established.

Fruitful.

KATO Supplement.
It's fruitless for fruitful compliance.

- tangy, tomato taste well accepted for long-term compliance
- B.I.D. regimen encourages compliance
- liquid form minimizes potential for gastrointestinal irritation
- corrects both hypokalemia and hypochloremic alkalosis
- convenient, easy-to-carry single-dose packets

KATO®
(potassium chloride
for oral solution) 20 mEq (1.5 g KCl)

SYNTEX

SYNTEX PUERTO RICO, INC.
HUMACAO, PUERTO RICO 00661

Please see prescribing information on following page.

A129

KATO
(potassium chloride for oral solution)

20 mEq (1.5 g KCl)

Prescribing Information

DESCRIPTION:
Spray-dried tomato powder containing 20 mEq potassium (equivalent to 1.5 g KCl) per 6 grams powder (one dose) with natural and synthetic flavors, spices and colors. Benzoic acid and potassium benzoate added as preservatives. When reconstituted as directed, makes a pleasantly flavored, low sodium tomato juice drink. Each daily dose (2 packets) contains approximately 0.5 mEq sodium.

INDICATIONS:
The prevention or correction of potassium deficit, particularly when accompanied by hypochloremic alkalosis in conjunction with thiazide diuretic therapy, in digitalis intoxication, or as the result of long-term corticosteroid therapy, low dietary intake of potassium, or excessive vomiting or diarrhea.

CONTRAINDICATIONS:
Potassium is contraindicated in severe renal impairment involving oliguria, anuria or azotemia; in untreated Addison's disease, familial periodic paralysis, acute dehydration, heat cramps, hyperkalemia from any cause. Potassium chloride should not be employed in patients receiving potassium-sparing agents such as aldosterone antagonists and triamterene.

PRECAUTIONS:
KATO is a concentrate and should be taken only after reconstituting with water as directed. This preparation, like other potassium supplements, must be properly diluted to avoid the possibility of gastrointestinal irritation. Do not use in patients with low urinary output or renal decompensation. Administer with caution; it is impossible to assess accurately the daily dose required. Excessive dosage may result in potassium intoxication. Frequent checks of the clinical status of the patient, ECG and/or plasma potassium level should be made. High plasma concentrations of potassium ion may cause death through cardiac depression, arrhythmias or arrest. Use with caution in patients with cardiac disease.

ADVERSE REACTIONS:
Vomiting, diarrhea, nausea, and abdominal discomfort may occur. Gross overdosage may produce signs and symptoms of potassium intoxication: mental confusion, listlessness, paresthesia of the extremities, weakness and heaviness of legs, flaccid paralysis, hyperkalemia, ECG abnormalities, fall in blood pressure, cardiac arrhythmias and heart block. The characteristic changes in the ECG are disappearance of the P wave, widening and slurring of QRS complex, changes of the S-T segment, tall peaked T waves, etc.

TOXICITY:
Potassium intoxication may result from overdosage of potassium or from therapeutic dosage in conditions stated under "Contraindications." Hyperkalemia, when detected, must be treated immediately because lethal levels can be reached in a few hours.

TREATMENT OF HYPERKALEMIA:
1. Dextrose solution 10% or 25% containing 10 units of crystalline insulin per 20 g dextrose, given I.V. in a dose of 300cc to 500cc in an hour. 2. Adsorption and exchange of potassium using sodium or ammonium cycle cation exchange resin, orally or as retention enema. 3. Hemodialysis or peritoneal dialysis. 4. Elimination of potassium-containing foods and medicaments. Warning: Digitalis toxicity can be precipitated by lowering the plasma potassium concentration too rapidly in digitalized patients.

ADMINISTRATION AND DOSAGE:
Mix with water to make a pleasant tomato juice drink. Each 6-gram unit dose packet provides 20 mEq of potassium. Usual adult dose—1 packet of KATO mixed with about 2 ounces of water twice daily—supplies 40 mEq potassium per day. Take with meals or follow with ½ glass of water. Larger doses may be required, but should be administered under close supervision because of the possibility of potassium intoxication.

HOW SUPPLIED:
Cartons of 30 and 120 6-gram unit dose packets, 20 mEq each.

CAUTION:
Federal law prohibits dispensing without a prescription.

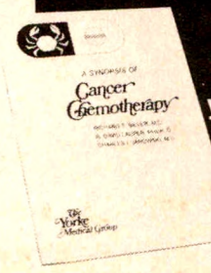
How to Keep Up with Drug Interaction in Cancer Chemotherapy



Three authorities from a leading medical center show you how to use the most current chemotherapeutic agents

A SYNOPSIS OF
Cancer Chemotherapy

At last a way to keep up with the bewildering proliferation of new chemotherapeutic drugs which have come into use relatively recently. This recently published guide will be valuable to every hospital, and every oncology specialist, general internist, clinical pharmacist, and nurse oncologist.

A SYNOPSIS OF CANCER CHEMOTHERAPY is a concise, readily understandable "how to" manual. Developed originally for staff use at The New York Hospital-Cornell Medical Center, the concept proved so successful it was decided to make it available to other professionals. The new users of the SYNOPSIS have the advantage of a proven, time-tested learning system. It is written in a unique, compact work-book style to keep reading time to a minimum.

The reader can quickly find the following for both commercially available and investigational drugs:
- Structure
- Mechanism of Action
- Pharmacokinetics
- Toxicity
- Therapy
- Availability

The chemotherapeutic agents in the main listing section cover these categories:
- Alkylating Agents
- Antimetabolites
- Mitotic Inhibitors
- Antibiotics
- Miscellaneous (includes such drugs as Mithramycin, Mitotane, etc.)

RICHARD T. SILVER, MD, F.A.C.P., F.A.B.C.O.
Chief, Oncology Service, Div. Hematology-Oncology. Clinical Professor of Medicine, Cornell University Medical College, Attending Physician, New York Hospital, Exec. Officer, Cancer & Leukemia Group B.

R. DAVID LAUPER, Pharm. D.
Asst. Director for Education and Information, Pharmacy Dept., New York Hospital-Cornell Medical Center.

CHARLES I. JAROWSKI, MD
Instructor in Medicine, Cornell University Medical College, Senior Chemotherapy Fellow, Div. of Hematology-Oncology, The New York Hospital.

Use it for 30 days—FREE

Refer to it for chemotherapeutic-drug information for a full month. Then keep the book only if you want it for permanent reference. Otherwise simply return it and owe nothing. You have nothing to lose and a whole world of valuable life-saving knowledge to gain. Order right now!

FAMOUS DOMES

One disposable dome stands out from every other in sight. Why? Probably because Bell & Howell's DISPOSADOME® excells in so many ways.

Some say they like the convenience . . . "It's so fast and easy!" (They refer to the individual snap-open sterile package and quick installation — you don't have to use a fluid between the membrane and the transducer diaphragm — and of course the disposable feature.)

Some quote the economy factor. (Yes, considering the time and labor costs for cleaning and sterilizing other types — plus the possibility of transducer damage — that's certainly true.)

Others agree to these advantages, but additionally cite the ready availability of either Linden or Luer fittings. (And, we might add, you can switch transducers or domes without disturbing the fluid path.)

Whatever your reasons for helping to make DISPOSADOME famous, you also have the assurance of the Bell & Howell name and experience. And that's really the best reason of all.

(DISPOSADOME is designed exclusively for use with Bell & Howell physiological pressure transducers.)

360 Sierra Madre Villa, Pasadena, California 91109 (213) 796-9381

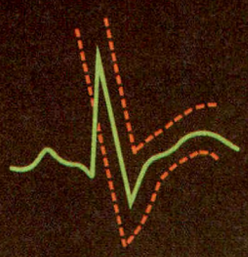
No other arrhythmia detection system gives you all three.

1



2

Dramatically reduced false alarms

We start with template matching—the preferred method—to discriminate between the patient's dominant beat and ectopics. But only Arrhythmia II adds two unique features to screen out artifact, ensuring that only qualified ectopic activity triggers alarms or is included in trends: (1) each abnormal beat must appear four times before it's accepted as a "true" ectopic class, and (2) our "over-range" circuitry suspends ECG processing for a minimum of five seconds when it detects excessive noise.

MEMORY BANK OF CLASSES		NUMBER OF OCCURRENCES 1	2	3	4	5	6	7 →

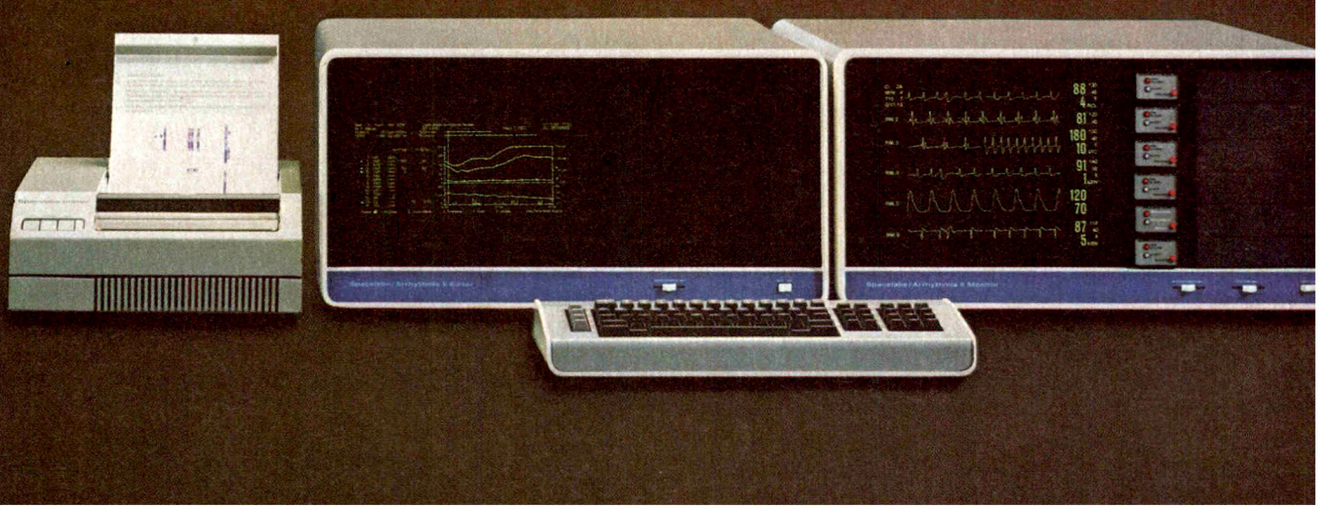
4-MATCH CRITERIA

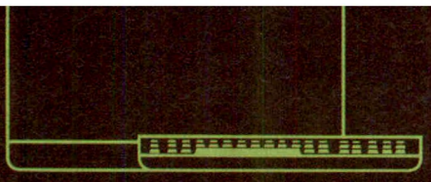
More meaningful patient information

Other computerized arrhythmia detection systems may accurately detect and record ectopic activity. But we just start there. Only Arrhythmia II allows you to select those ectopics that are particularly important for a patient and to include only those ectopics in trends. You can quickly recall classes of ectopics and their frequency over 24 hours. And, on the Editor, you can trend a specific class or combination of classes for 1, 2, 8 or 24 hours, without having to edit out each occurrence of unwanted information.

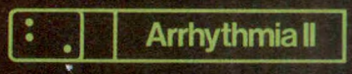
Arrhythmia II



3

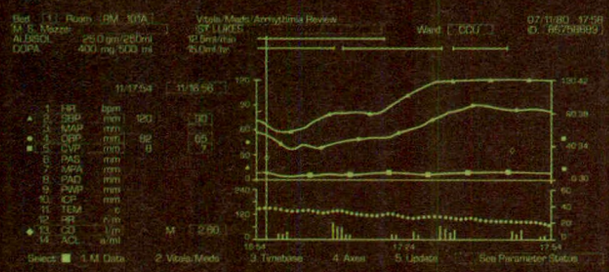


4



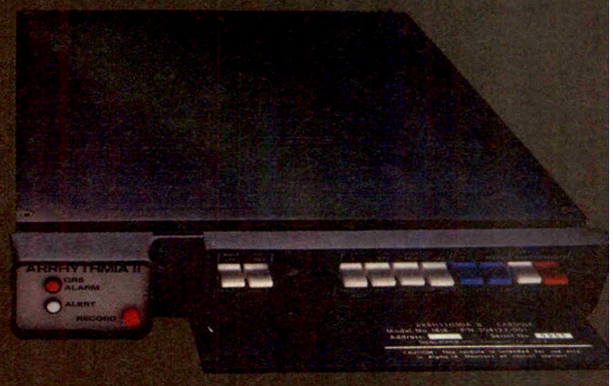
See effects of treatment on one screen

Only Arrhythmia II lets you trend medications, ectopics and vital signs on one display, in a concise and easy-to-interpret format. And it provides 24-hour recall so the precise information on ectopics, vital signs and medications is available for any specific time.

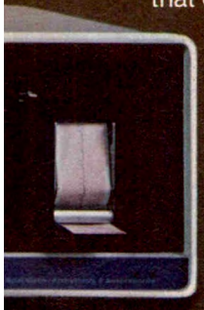


A computer for each patient

Hospitals using minicomputer systems have experienced the loss of critical data on all patients connected to the system when the computer malfunctions. But that can't happen with Arrhythmia II, because each patient has his own computer. And any malfunction only affects that one patient. The microprocessor-based cardule can then be replaced in minutes and easily repaired by simply inserting a new circuit board.



We designed Arrhythmia II to solve clinical problems that other arrhythmia systems have not even tried to solve. We feel it represents our care and concern in applying technology to the clinical setting—an approach that has made Spacelabs the fastest growing company in patient monitoring today.



But you don't have to take our word for it. Call us today (213-882-9560, collect) to arrange for an evaluation in *your* hospital. Then we think you'll agree with the growing number of your colleagues who believe that Arrhythmia II is the best system available.

For **every** professional with an interest in Exercise and the Heart.

EXERCISE in Cardiovascular Health and Disease

Edited by
Ezra A. Amsterdam, MD, Chief Coronary Care Unit, Univ. of Calif. School of Medicine
Jack H. Wilmore, PhD, Professor and Head Dept. of Physical Education & Athletics, Univ. Arizona
Anthony N. DeMaria, MD, Dir. Echocardiography Section, Univ. of Calif. School of Medicine

SEPTEMBER 1977, 408 PAGES, ILLUS.

This comprehensive work covers every aspect of exercise and its role in Diagnosis, Treatment, and Prevention of cardiac disease.

The scope of EXERCISE IN CARDIOVASCULAR HEALTH AND DISEASE is so broad that it goes from something as basic as a detailed study of the heart muscle itself to the latest advances in cardiac rehabilitation.

Special attention is given to such subjects as:

- ☐ Present status of exercise testing and training in terms of physiological bases and clinical applications
- ☐ Nuclear cardiology
- ☐ Computer analysis of the exercise ECG
- ☐ Stress myocardial scintigraphy
- ☐ Various interpretations of exercise tests in the asymptomatic population

The editors have brought together a distinguished group of specialists—all of whom have made major contributions to the field. Included are outstanding scientists, clinicians, exercise physiologists, and physical educators.

For you who have any interest—professional or personal—in exercise and the heart, we urge you to *look* at a copy of EXERCISE IN CARDIOVASCULAR HEALTH AND DISEASE. That's right! You're invited to *look* it over before buying it.

Send for your copy of Exercise in Cardiovascular Health and Disease today. *Then use it for 30 days without risk.*

KLOTRIX®

(POTASSIUM CHLORIDE)
SLOW-RELEASE TABLETS 10 mEq

DESCRIPTION KLOTRIX is a film-coated (not enteric-coated) tablet containing 750 mg potassium chloride (equivalent to 10 mEq) in a wax matrix. This formulation is intended to provide a controlled release of potassium from the matrix to minimize the likelihood of producing high localized concentrations of potassium within the gastrointestinal tract.

INDICATIONS— BECAUSE OF REPORTS OF INTESTINAL AND GASTRIC ULCERATION AND BLEEDING WITH SLOW-RELEASE POTASSIUM CHLORIDE PREPARATIONS, THESE DRUGS SHOULD BE RESERVED FOR THOSE PATIENTS WHO CANNOT TOLERATE OR REFUSE TO TAKE LIQUID OR EFFERVESCENT POTASSIUM PREPARATIONS OR FOR PATIENTS IN WHOM THERE IS A PROBLEM OF COMPLIANCE WITH THESE PREPARATIONS.

1. For therapeutic use in patients with hypokalemia with or without metabolic alkalosis; in digitalis intoxication and in patients with hypokalemic familial periodic paralysis.
2. For prevention of potassium depletion when the dietary intake of potassium is inadequate in the following conditions: Patients receiving digitalis and diuretics for congestive heart failure; hepatic cirrhosis with ascites; states of aldosterone excess with normal renal function; potassium-losing nephropathy, and certain diarrheal states.
3. The use of potassium salts in patients receiving diuretics for uncomplicated essential hypertension is often unnecessary when such patients have a normal dietary pattern. Serum potassium should be checked periodically, however, and, if hypokalemia occurs, dietary supplementation with potassium-containing foods may be adequate to control milder cases. In more severe cases supplementation with potassium salts may be indicated.

CONTRAINDICATIONS In patients with hyperkalemia, since a further increase in serum potassium concentration in such patients can produce cardiac arrest. Hyperkalemia may complicate any of the following conditions: chronic renal failure, systemic acidosis such as diabetic acidosis, acute dehydration, extensive tissue breakdown as in severe burns, adrenal insufficiency, or the administration of a potassium-sparing diuretic (*eg*, spironolactone, triamterene).
Wax-matrix potassium chloride preparations have produced esophageal ulceration in certain cardiac patients with esophageal compression due to enlarged left atrium.
All solid dosage forms of potassium supplements are contraindicated in any patient in whom there is cause for arrest or delay in tablet passage through the G.I. tract. In these instances, potassium supplementation should be with a liquid preparation.

WARNINGS Hyperkalemia: In patients with impaired mechanisms for excreting potassium, administration of potassium salts can produce hyperkalemia and cardiac arrest. This occurs most commonly in patients given potassium intravenously but may also occur when given orally. Potentially fatal hyperkalemia can develop rapidly and be asymptomatic. Use of potassium salts in patients with chronic renal disease, or any other condition which impairs potassium excretion requires particularly careful monitoring of the serum potassium concentration and appropriate dosage adjustment.
Interaction with potassium-sparing diuretics: Hypokalemia should not be treated by the concomitant administration of potassium salts and a potassium-sparing diuretic (*eg*, spironolactone or triamterene), since the simultaneous administration of these agents can produce severe hyperkalemia.
Gastrointestinal lesions: Potassium chloride tablets have produced stenotic and/or ulcerative lesions of the small bowel and deaths. These lesions are caused by a high localized concentration of potassium ion in the region of a rapidly dissolving tablet, which injures the bowel wall and thereby produces obstruction, hemorrhage, or perforation. KLOTRIX is a wax-matrix tablet formulated to provide a controlled rate of release of potassium chloride and thus to minimize the possibility of a high local concentration of potassium ion near the bowel wall. While the reported frequency of small-bowel lesions is much less with wax-matrix tablets (less than one per 100,000 patient-years) than with enteric-coated potassium chloride tablets (40-50 per 100,000 patient-years) cases associated with wax-matrix tablets have been reported both in foreign countries and in the United States. In addition, perhaps because the wax-matrix preparations are not enteric-coated and release potassium in the stomach, there have been reports of upper gastrointestinal bleeding associated with these products. The total number of gastrointestinal lesions remains less than one per 100,000 patient-years. KLOTRIX should be discontinued immediately and the possibility of bowel obstruction or perforation considered if severe vomiting, abdominal pain, distention, or gastrointestinal bleeding occurs.
Metabolic acidosis: Hypokalemia in patients with metabolic *acidosis* should be treated with an alkalinizing potassium salt such as potassium bicarbonate, potassium citrate, or potassium acetate.

PRECAUTIONS Potassium depletion is ordinarily diagnosed by demonstrating hypokalemia in a patient with a clinical history suggesting some cause for potassium depletion. In interpreting the serum potassium level, the physician should bear in mind that acute alkalosis *per se* can produce hypokalemia in the absence of a deficit in total body potassium, while acute acidosis *per se* can increase the serum potassium concentration into the normal range even in the presence of a reduced total body potassium. Treatment of potassium depletion particularly in presence of cardiac disease, renal disease, or acidosis, requires careful attention to acid-base balance and appropriate monitoring of serum electrolytes, electrocardiogram and clinical status of patient.

ADVERSE REACTIONS Most common to oral potassium salts: nausea, vomiting, abdominal discomfort, and diarrhea. These symptoms are due to irritation of the gastrointestinal tract and are best managed by diluting the preparation further, taking the dose with meals, or reducing the dose. One of the most severe adverse effects is hyperkalemia (see Contraindications and Warnings). There also have been reports of upper and lower gastrointestinal conditions including obstruction, bleeding, ulceration and perforation (see Contraindications and Warnings); other factors known to be associated with such conditions were present in many of these patients. Skin rash has been reported rarely.

DOSAGE Usual dietary intake potassium by the average adult is 40 to 80 mEq per day. Potassium depletion sufficient to cause hypokalemia usually requires loss of 200 or more mEq of potassium from the total body store.
Dosage must be adjusted to the individual needs of each patient but is typically in the range of 20 mEq per day for prevention of hypokalemia to 40-100 mEq per day or more for treatment of potassium depletion.
Note: KLOTRIX slow-release tablets must be swallowed whole and never crushed or chewed.
HOW SUPPLIED Bottles of 100.

SOPHISTICATED, SIMPLE

AND DELIVERABLE.

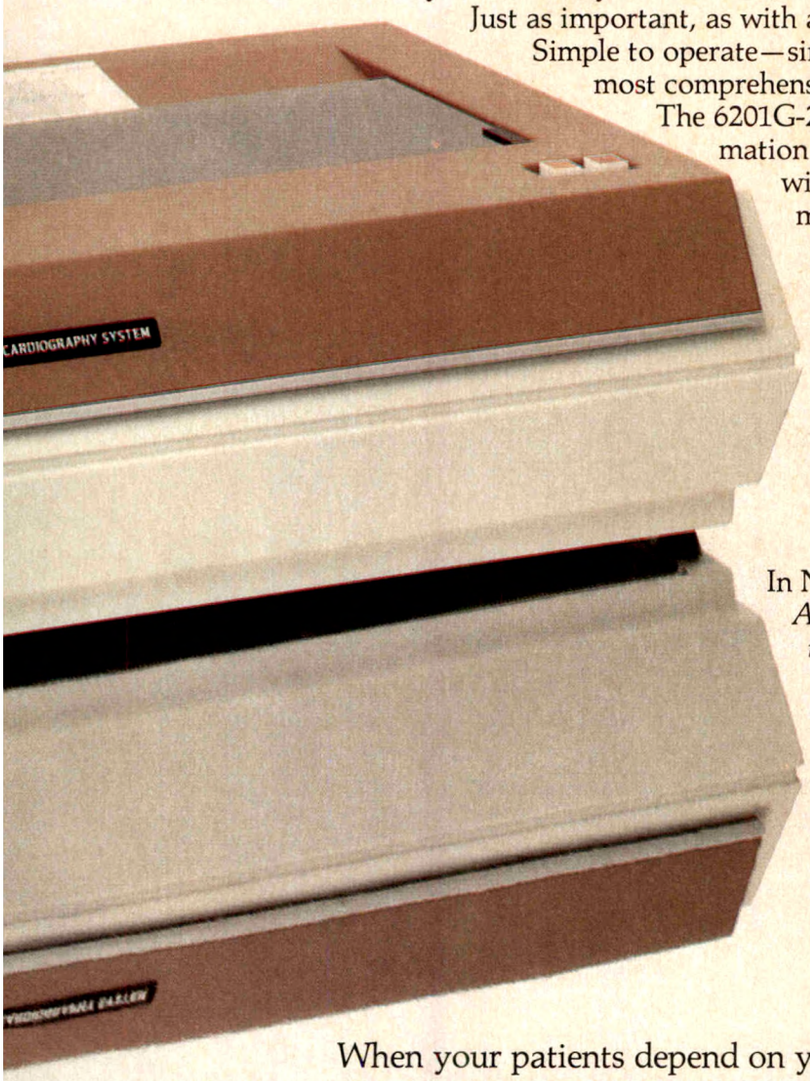
The ICR 6201G-2b: an information breakthrough in Holter cardiography.

A breakthrough in Holter cardiography doesn't do medicine a bit of good if it's still on the drawing board. At ICR, not only can *every* Holter system we make be delivered quickly and dependably, but each is also the result of an aggressive clinical evaluation program.

For instance, our new 6201G-2b Holter system is *ready right now for day-to-day use.* It's the most sophisticated ever developed.

Sophisticated in terms of its microprocessor design, its superior range of scanning functions, and its sensitivity to and analyses of cardiac information.

Just as important, as with all ICR Holter systems, *it's simple.* Simple to operate—simple to upgrade—and simply the most comprehensive system available.



The 6201G-2b allows you to choose the information summary format you prefer from a wide range of options. This flexibility makes the 6201G-2b the most practical and powerful Holter system ever developed.

ICR makes a full range of Holter systems to meet virtually any diagnostic or budget consideration. We build these systems to *your exact needs.*

Call toll-free
1-(800)-448-1675.

In New York, call collect: (315) 437-7291.

Ask for a copy of our beautifully illustrated "Failsafe Holter Hook-up" poster and more information on the wide range of ICR Holter systems. Or write: Instruments for Cardiac Research, 6057 Corporate Drive, East Syracuse, N.Y. 13057, U.S.A.

When your patients depend on you, depend on our technology.

CARDIOLINE®

A living presence

CARDIOLINE - thirty years of experience in the field of recording electromedical phenomenon and of collaboration with the medical profession.
CARDIOLINE - technology and know-how resulting from daily marketing and the diligent development of cardiological equipment throughout the world.
CARDIOLINE - in hospitals, diagnostic centres, outpatient clinics and private medical studios - a living presence.

CARDIOLINE equipments are made in accordance with the most stringest international Safety Standards (I.E.C. 601/1 ⊡♥).

In addition, they are based on a "completely modular" concept; they can be run both on mains supply or on battery and are therefore completely reliable in all places under all conditions.
In short, eta-system stands for accurate and essential design made in functional and practical materials.
Thanks to these "guarantees" the Cardioline eta-system appliances have become a constant aid in the support and at the service of the medical profession.

Congestive Heart Failure

Mechanisms, Evaluation and Treatment
Dean T. Mason, M.D.

This rare treatment of such a multifaceted subject provides an unusual opportunity for the busy clinician to add to his knowledge in a minimum amount of time. Any area of immediate interest can be rapidly located and as much data as needed can be quickly extracted. The concentration on improved clinical management will be appreciated by every internist, cardiologist, generalist, and any professional involved in cardiovascular medicine.

Dean Mason, President of the American College of Cardiology, has organized this monograph within the three areas relevant to an understanding of congestive heart failure: *mechanisms, evaluation* and *treatment*. Fifty-six recognized authorities have been assembled by Dr. Mason, each contributing their expertise to make this book the foremost text covering the highly important and common disorders of abnormal heart function.

This presentation of recent advances in basic research and clinical progress has been highly acclaimed for its major contribution to the improvement of patient care. We invite you to see if you don't agree. Order and take 30 days to look over the book. If you're not totally satisfied, return it.

About the author . . . Dean T. Mason, M.D.

Professor of Medicine, Professor Physiology, Chief of Cardiovascular Medicine, University of California, School of Medicine, Davis.

President, American College of Cardiology; President, Western Society for Clinical Research.

Member of the American Board of Internal Medicine Cardiovascular Diseases.

Has authored more than 400 original articles on cardiovascular science and clinical cardiology.

Serves on the editorial boards of The American Journal of Cardiology, The Journal of Clinical Investigation, Circulation, Chest, Clinical Pharmacology and Therapeutics, Catheterization and Cardiovascular Diagnosis, and Heart and Lung.

Recipient of Experimental Therapeutics Award in 1973 from the American Society of Pharmacology and Experimental Therapeutics, the Research Awards in 1965 from the American Therapeutic Society, and the Theodore and Susan B. Cummings Humanitarian Awards in 1972, 1973, and 1975 from the U.S. State Department and the American College of Cardiology.

YORKE MEDICAL BOOKS 666 Fifth Avenue, N.Y., N.Y. 10103

Please send me a copy of CONGESTIVE HEART FAILURE for 30 days free examination and use. If I decide to keep it, your invoice will be honored ($35.00 plus shipping cost). Otherwise, the book will be returned for full credit or refund.

☐ Full payment enclosed, publisher absorbs shipping cost.
☐ Send invoice (U.S. and Canada only)
Countries outside Western Hemisphere: $40.00 prepaid in U.S. funds.

Aldactone®
(spironolactone)

WARNING
Spironolactone has been shown to be a tumorigen in chronic toxicity studies in rats (see Warnings). Aldactone should be used only in those conditions described under Indications. Unnecessary use of this drug should be avoided.

Indications: *Diagnosis and treatment of primary hyperaldosteronism. Essential hypertension, edema of congestive heart failure and the nephrotic syndrome, when other measures are considered inappropriate. Cirrhosis of the liver accompanied by edema and/or ascites. Hypokalemia.*

Contraindications: *Anuria, acute renal insufficiency, significant impairment of renal function, or hyperkalemia.*

Warnings: *Excessive potassium intake may cause hyperkalemia. Potassium supplements should not be given with Aldactone. Do not administer concurrently with other potassium-sparing diuretics.*

Spironolactone has been shown to be a tumorigen in chronic toxicity studies in rats. In one study using 25, 75, and 250 times the usual daily human dose (2 mg./kg.) there was a statistically significant dose-related increase in benign adenomas of the thyroid and testes. In female rats there was a statistically significant increase in malignant mammary tumors at the mid-dose only. In male rats there was a dose-related increase in proliferative changes in the liver. At the highest dosage level (500 mg./kg.) the range of effects included hepatocytomegaly, hyperplastic nodules and hepatocellular carcinoma; the last was not statistically significant.

Precautions: *Patients should be carefully evaluated for possible disturbances of fluid and electrolyte balance. Hyperkalemia may occur in patients with impaired renal function or excessive potassium intake and can cause cardiac irregularities which may be fatal. Hyponatremia may be caused or aggravated, especially when Aldactone is administered in combination with other diuretics. Transient elevation of BUN and/or mild acidosis may occur. Aldactone potentiates the effect of other diuretics or antihypertensive agents, particularly ganglionic blocking agents; therefore the dosage of such drugs should be reduced by at least 50 percent when adding Aldactone. Gynecomastia may develop and in rare instances some breast enlargement may persist. Vascular responsiveness to norepinephrine may be reduced.*

Spironolactone may cross the placental barrier. Use in pregnant women requires that the anticipated benefit be weighed against possible hazard to the fetus. Breast feeding should be discontinued when Aldactone is being used.

Adverse Reactions: *Gynecomastia is observed not infrequently. Gastrointestinal symptoms including cramping and diarrhea, drowsiness, lethargy, headache, maculopapular or erythematous cutaneous eruptions, urticaria, mental confusion, drug fever, ataxia, inability to achieve or maintain erection, irregular menses or amenorrhea, postmenopausal bleeding, hirsutism and deepening of the voice. Carcinoma of the breast has been reported but a cause-and-effect relationship has not been established. Adverse reactions are usually reversible upon discontinuation of the drug.*

Dosage and Administration

For primary hyperaldosteronism: *400 mg. daily for three to four weeks (long test), or for four days (short test). For preparation for surgery or for long-term maintenance therapy, 100 to 400 mg. daily.*

For edema in adults: *Initial daily dosage is 100 mg. in divided doses but may range from 25 to 200 mg. daily. If after five days an adequate diuretic response has not occurred, a second diuretic which acts more proximally in the renal tubule may be added. The dosage of Aldactone should remain unchanged when other diuretic therapy is added.*

For edema in children: *Initial daily dosage should provide approximately 1.5 mg. per pound of body weight (3.3 mg./kg.) in divided doses.*

For essential hypertension: *Initial adult daily dosage of 50 to 100 mg. in divided doses, alone or with diuretics which act more proximally in the renal tubule, or with other antihypertensive agents. Continue treatment for at least two weeks since maximal response may not occur before this time. Adjust subsequent dosage according to patient response.*

For hypokalemia: *25 to 100 mg. daily in divided doses.*

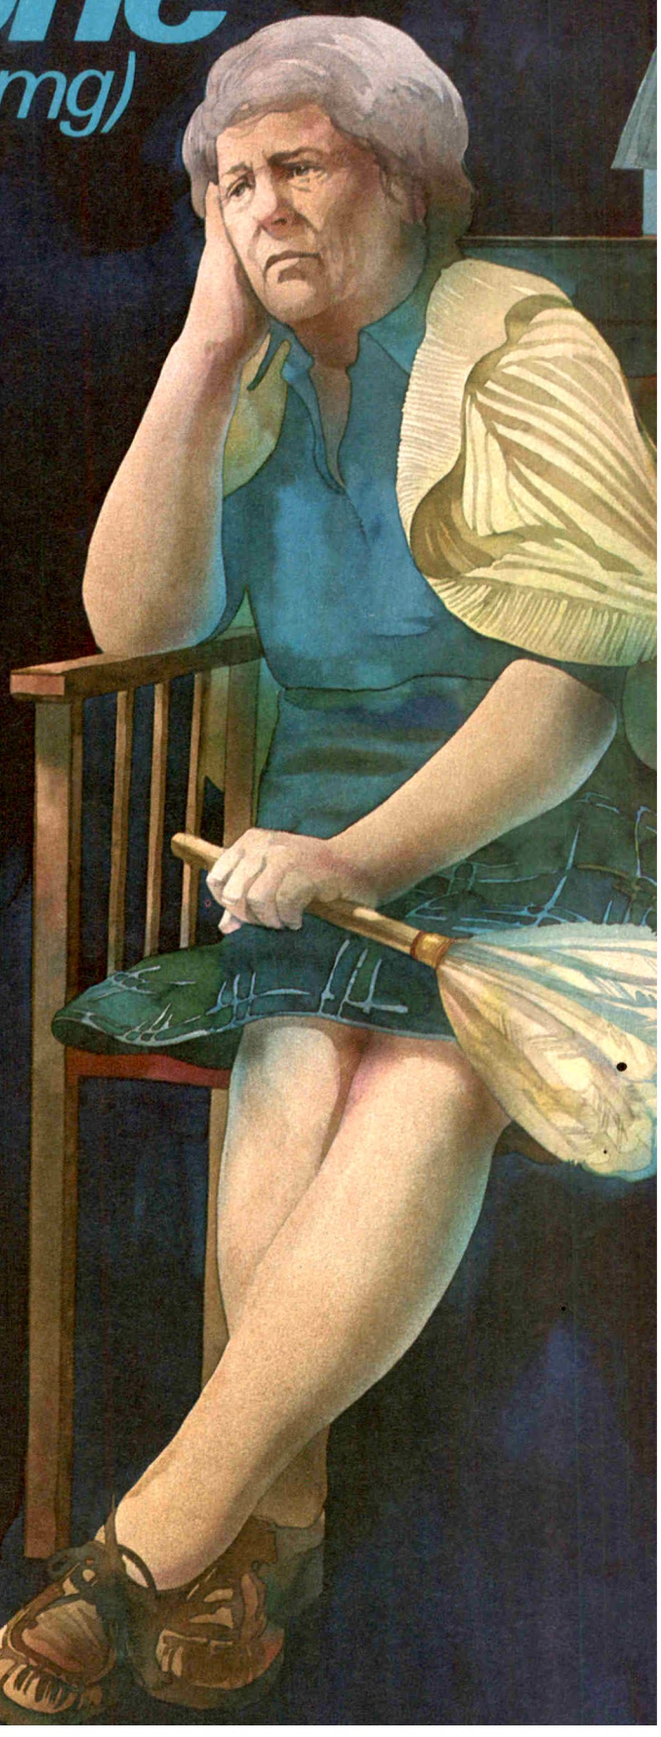
When other measures are considered inadequate or inappropriate

Aldactone®
(spironolactone 25 mg)

The uncomplicator in CHF therapy



"Round-the-house" edema, electrolyte washout, subtle secondary volume buildup

☑ *Aldactone, an effective diuretic in its own right, also enhances the efficacy of other diuretic agents.*

☑ *The unique potassium-regulating mechanism of Aldactone can prevent hypokalemia with limited risk of hyperkalemia. This helps protect your patient from digitalis-induced arrhythmias.*

☑ *Unlike other potassium-sparers, Aldactone specifically antagonizes aldosterone, thereby mitigating secondary volume buildup.*

For these reasons, Aldactone is a valuable adjunct in the treatment of CHF.

Limitations to Consider: *Spironolactone has been shown to be a tumorigen in chronic toxicity studies in rats. Thus, Aldactone should be prescribed only when other measures are considered inadequate or inappropriate. (See boxed warning and* Warnings *section of Aldactone prescribing information.)*

Before prescribing, please consult the complete prescribing information, a brief summary of which appears on the preceding page.

Continued Gains in Hypertension*

EDWARD D. FROHLICH, MD, FACC

New Orleans, Louisiana

During the decade of the 1970s dramatic achievements were realized in the field of hypertension. The prior decade witnessed the introduction of a remarkable array of antihypertensive therapeutic agents: diuretic drugs, beta adrenergic receptor blocking drugs, other sympathetic inhibitors and oral and parenteral vasodilators. The impact of these major achievements in therapy is still being appreciated in other areas of cardiovascular medicine (for example, vasodilating therapy for heart failure).

Treatment of Hypertension in the 1970s

The first fruits from these contributions were the data reported from the Veterans Administration Cooperative Studies on hypertension, ably led by Edward D. Freis.[1–3] These studies conclusively demonstrated the merits of systematic antihypertensive drug therapy in reducing morbidity and mortality from the complications of hypertensive cardiovascular disease in patients whose diastolic blood pressure exceeded 104 mm Hg. As a result of this landmark study, Elliot Richardson, the then Secretary of Health, Education, and Welfare, and Theodore Cooper established the High Blood Pressure Education Program and permitted the granting of funds for the Hypertension Detection and Follow-Up Program.

The initial reports from the 5 year prospective study involving 14 medical centers and almost 11,000 treated patients were published at the end of the decade.[4,5] These studies indicated that vigorous treatment of female as well as male patients of all ages with diastolic pressure in excess of 90 mm Hg was associated with significant reduction in both cardiovascular and noncardiovascular mortality. Thus, the merits of vigorous pharmacologic antihypertensive therapy were established in the 1970s. The interested reader is referred to these now-classic cardiovascular therapeutic documents[1–5] for details of these studies; this is not the purpose of the present editorial.

The reason for this communication is to draw attention to the most recent reports concerned with the ongoing saga of successes in hypertension. Total cardiovascular deaths have declined from 54 percent at the beginning of the 1970s to 50 percent at the end. This sharp break in the downslope of this mortality curve may be related temporally to the dissemination of a series of recommendations by a Joint National Committee of authorities concerned with the detection, evaluation and treatment of high blood pressure. To be sure, it is always unwise to attribute a cause of a multifactorial problem to one agent. The decade of the 1970s was associated not only with widespread implementation of the Joint National Committee's recommendations through the High Blood Pressure Education Program but also with a decline in cigarette smoking; greater public consciousness of dietary controls (caloric, animal fat and sodium intake, for example); widespread establishment of hospital coronary intensive care units; development of mobile ambulance services; and even the phenomenon of the 1970s—jogging. Nevertheless, when one closely scrutinizes the data, the reduction in death rate could be related importantly to the decline in mortality from strokes.[6] And if we know of one major risk factor related to this reduction, it surely would be control of the abnormally elevated arterial pressure.[7] Thus, we see the merits of a vigorous antihypertensive treatment program and the birth of a new era of cardiovascular medicine—preventive cardiology.[8]

Hypertension in the 1980s

And now we have entered into the 1980s. Already we have seen major contributions. First, we have learned

From the Alton Ochsner Medical Foundation and Ochsner Clinic, New Orleans, Louisiana. Dr. Frohlich is Representative of the American College of Cardiology to the High Blood Pressure Education Program Coordinating Committee. Manuscript received October 27, 1980, accepted November 19, 1980.

Address for reprints: Edward D. Frohlich, MD, Alton Ochsner Medical Foundation, 1516 Jefferson Highway, New Orleans, Louisiana 70121.

* Editorials published by the Journal reflect the views of the authors and do not necessarily represent the views of the Journal or of the American College of Cardiology.

ıat pharmacologic control of arterial pressure is es-
ntial for patients with diastolic pressure in excess of
) mm Hg. This was shown by the compelling data of
ıe Hypertension Detection and Follow-up Program.
nd we now have further inklings from multinational
ıoperative studies indicating that antihypertensive
ıerapy may be expected to reduce morbidity and
ortality from events related to ischemic heart disease.
he first report from Australia has recently been pub-
ıhed,[9] and we can anticipate similar reports from Great
ritain, Scandinavia and the United States.

A revised report from the Joint National Committee
ıs just been published presenting in detail the current
inking of experts concerned with detection, evaluation
ıd management of patients with hypertension.[10] And
ıcause the lower limit of diastolic pressure elevation recommended for treatment has been reduced from 105 to 90 mm Hg, we now include among the potential beneficiaries of therapy upwards of 54—not 23—million Americans.

The American College of Cardiology is pleased with its role in this success story. The College is a charter member of the High Blood Pressure Education Program and has been ably served on the Joint National Committee by a practicing cardiologist member and Joint National Committee vice-chairman; this physician, Dr. Marvin Moser, has been part-time consultant to the High Blood Pressure Education Program. We can anticipate, with great confidence, that with continued contributions in "preventive cardiology" the mortality rates from cardiovascular diseases will be reduced even further in the 1980s.

The Laennec Bicentennial*

PAUL D. KLIGFIELD, MD

New York, New York

Cardiologists in the United States join with physicians around the world this month in remembering René Théophile Hyacinthe Laennec on the occasion of the bicentennial of his birth. Quite naturally, the inventor of the stethoscope remains honored in his native France, where many of the historic locations associated with the frail but energetic Breton who founded bedside chest diagnosis may be visited.

Laennec was born in February 1781 in Quimper, a port city in western Brittany. His birthplace along the Rue de Quai adjacent to the river Odet no longer exists, but an imposing memorial statue has been erected that overlooks the Place St. Corentin next to the town's great gothic cathedral. In Nantes, Laennec's childhood home still stands in the Place Buffay, the site of one of the Terror's most active guillotines. Although the old Hôtel Dieu of Nantes has been thoroughly modernized, a small room in the nearby medical school library has been dedicated to the discoverer of mediate auscultation and contains a fascinating exhibit of texts, portraits, manuscript material and personal memorabilia relating to Laennec. One of his residences in Paris stands unmarked at 23, Rue du Cherche Midi, a brisk walk from the Hôpital Necker, where in 1816, a rolled quire of paper served as the first stethoscope and where today, Laennec's achievement is commemorated by a plaque at the hospital's outer gate.

A short drive from Quimper leads to the wooded manor of Kerlouarnec, the country home near Ploaré to which Laennec frequently retired in ill health after publication of *De l'Auscultation Médiate* in 1819. It is now a private estate. Here, surrounded by his beloved Breton fields, Laennec died in 1826 at the age of 45. His simple grave may be visited in the nearby hillside cemetery along the road leading to Douarnenez. But clearly, his true memorial exists every time we examine a patient.

Insight into the personality of Laennec is available in the English translation of Kervran's biography,[1] which supplements more traditional accounts of his life and times.[2,3] The splendid comprehensive biography by Rouxeau[4,5] has not been translated. A recent facsimile of the 1821 English edition of Laennec's masterpiece is available[6] for those who wish to review his classic observations.

FIGURE 1. Statue of Laennec in the Place St. Corentin, Quimper.

INVITATION FROM THE PRESIDENT

It is a privilege for me to extend a personal invitation to you and your family to attend the 30th Annual Scientific Session of the College in San Francisco, March 15–19, 1981.

The Scientific Program Committee, Co-chaired by Drs. Emilio Giuliani and Dwight McGoon, have developed a broad comprehensive program that will have areas devoted to the entire spectrum of cardiovascular disease, from the basic sciences to diagnosis, management, and prevention. Mini-Courses, Core Curricula, Self-Assessment, Symposia, Luncheon and Fireside Panels, and Meet the Experts sessions will enable you to hear and have involvement with recognized experts. Progress and new knowledge will be reflected in the sessions of submitted papers on original investigation, the sessions on Controversies in Cardiology, and in the special lectures.

Doctor Hilliard J. Katz is in charge of local arrangements with the marvelous ambience of San Francisco as his backdrop. He and the members of his committee have proposed some interesting and unique programs that will reflect the cosmopolitan and cultural features of the great western city.

I look forward to seeing you and welcoming you to this 30th Annual Scientific Meeting of our College. I am certain you will find it stimulating and scientifically challenging. In addition, you will find the social and cultural aspects outstanding.

Robert O. Brandenburg, MD, FACC
President, 1980–81
American College of Cardiology

GREETINGS FROM SAN FRANCISCO

I am pleased to report that plans for the 30th Annual Scientific Session of the American College of Cardiology in San Francisco are rapidly developing in an effort to surpass the success of the 1973—22nd Annual Scientific Session held in our favorite city by the Golden Gate. San Francisco needs no introduction as one of the world's most attractive cities with unmatched cultural, culinary and geographic opportunities for delightful visiting and enjoyment. The Golden Gate Bridge, Chinatown, Japanese Tea Gardens, Fisherman's Wharf, Nob Hill Fine Arts Museums and Performing Arts Center all are part of our fascinating city.

A stimulating Hospitality Program provides varied opportunities to visit many of the outstanding local attractions such as half or full day tours to the famous Flower Mart and Orchid Farms, and to Victorian, traditional and modern homes, as well as ferry boat trips and architectural walks. Additional offerings of visits to the various ethnic areas of the city will be available. The program will also provide in-house lectures with wide appeal.

I look forward to seeing you in San Francisco.

Hilliard J. Katz, MD, FACC
Chairman, Local Arrangements Committee
30th Annual Scientific Session

REMARKS FROM THE SCIENTIFIC PROGRAM COMMITTEE

The Scientific Program Committee cordially welcomes you to the 30th Annual Scientific Session of the American College of Cardiology. In this age of rapidly expanding knowledge of the heart and improving management of its diseases, the Annual Program of the College should overview the entire broadly advancing field, look more deeply into specific areas of interest, and provide the means for dialogue at all levels. To this end, a wide variety of educational sessions has been arranged.

The *Core Curricula* run throughout the program, bringing to the practitioner comprehensive current knowledge relevant to modern approaches to specific clinical problems. The *Symposia,* also scheduled for each day of the program, provide in-depth analyses of a wide variety of specifically focused topics. The greater informality and variety of *Luncheon* and *Fireside Panels* are designed to facilitate interchange between the panel of experts and their audiences concerning a broad range of practical problems. The ultimate opportunity for dialogue is provided by the *Meet the Experts* sessions, wherein a pair of authorities visit openly with a small group of attendees. Considerable excitement surrounds the *Controversies in Cardiology*—debates about timely but unsettled issues. Because of its popularity, this year two sessions of *Controversies* are planned, rather than one as in years past. The program this year has been expanded to allow presentation of even more *Original Contributions* by leading workers from around the world. These sessions are grouped into broad categories of interest. Additional high points of the program are the *Young Investigators Awards Competition,* the *Self-Assessment* program, the *Opening Plenary Address* (*Franz Groedel Lecture*), and the *Louis F. Bishop Lecture.*

Still another excellent opportunity to expand the educational experience of the Annual Meeting is provided on the Sunday prior to the formal Scientific Sessions, in the form of *Mini-Courses.* These are in-depth workshops on a variety of timely areas of interest.

The Scientific Program Committee earnestly hopes that its efforts to organize this ambitious program will prove to be rewarding to each participant and each person in attendance. If so, the credit will belong to the expertise, cooperation, and selfless dedication of the members of the Committee, the many session Chairmen and others who have given invaluable advice, President Brandenburg who worked closely with the Committee, the staff of the College, and Julianne E. Osborn, Program Coordinator.

The 1981 Scientific Program Committee: Robert O. Brandenburg, MD; C. Richard Conti, MD, Coordinator of Luncheon and Fireside Panels: Jesse E. Edwards, MD; Richard E. Kerber, MD, Coordinator of Core Curricula sessions; Richard P. Lewis, MD; Dan G. McNamara, MD; Eldred D. Mundth, MD, Coordinator of Controversies in Cardiology sessions; Jacqueline A. Noonan, MD, Coordinator of Mini-Courses; Bertram Pitt, MD; Charles E. Rackley, MD; Richard O. Russell, Jr., MD; James Scheuer, MD, Coordinator of Meet the Experts sessions; James A. Shaver, MD, Coordinator of Symposia sessions; Arnold M. Weissler, MD.

Emilio R. Giuliani, MD, FACC
Co-Chairman, 1981 Scientific Program Committee

Dwight C. McGoon, MD, FACC
Co-Chairman, 1981 Scientific Program Committee

THIRTIETH ANNUAL SCIENTIFIC SESSION
GENERAL INFORMATION

Every effort has been made to organize the 1981 Annual Meeting in such a way that it provides a productive and worthwhile experience for all in attendance.

San Francisco Registration Schedule

General Registration:

San Francisco Hilton Hotel

Date	Hours
Saturday, March 14	1:00 p.m.–6:00 p.m.
Sunday, March 15	7:00 a.m.–6:00 p.m.

Main Lobby, Civic Auditorium

Date	Hours
Monday, March 16	7:00 a.m.–5:00 p.m.
Tuesday, March 17	8:00 a.m.–5:00 p.m.
Wednesday, March 18	8:00 a.m.–5:00 p.m.
Thursday, March 19	8:00 a.m.–12:00 Noon

Hospitality Registration:

Beginning at 8:00 a.m., Sunday, March 15 in the Georgian Room Foyer of the Hotel St. Francis.

Registration Fee

There is no registration fee for the members of the American College of Cardiology, program participants and scientific exhibitors. Non-member fee is one hundred and fifty dollars. Medical students, interns, residents, fellows, nurses, and technicians may attend without fee as guests of the American College of Cardiology **upon presentation of a letter of certification.** (Letter of certification **must** accompany advance registration card. If registering at the meeting, letter of certification **must be shown** to personnel at registration counter in San Francisco.)

Requests for refund of registration fee, Mini-Courses, Meet the Experts, Luncheon or Dinner-Dance will be honored if received in the College office in writing by Friday, February 27, 1981.

Presentation of Submitted Papers

Ten minutes for presentation and three minutes for discussion is the time limit for each paper.

Continuing Medical Education Credit

As an organization accredited for continuing medical education, the American College of Cardiology certifies that this continuing education offering meets the criteria for 20 1/2 credit hours in Category 1, provided it is used and completed as designed. For credit which may be acceptable to state medical associations, specialty societies, or state boards of medical licensure, please contact those organizations.

Each Luncheon Panel attended meets the criteria for 1 credit hour in Category 1.
Each Mini-Course attended meets the criteria for 3 credit hours in Category 1.
Each Fireside Panel attended meets the criteria for 1 1/2 credit hours in Category 1.

Luncheon Panels

Seating is limited at these sessions; therefore, early reservation of luncheon tickets is advisable. **Admission to the luncheon panel discussion is by ticket only.** The Advance Registration Form provides for the reservation of your choice.

Mini-Courses

Registration is limited for each course; therefore, early reservation of Mini-Course tickets is essential to assure a place in the subject of your choice. **Admission to the Mini-Courses is by ticket only.** The Advance Registration Form provides for the reservation of your choice.

Fireside Panels

The Fireside Panels will be held in the Hotel St. Francis and the San Francisco Hilton Hotel. Tickets are not required for Firesides. Attendance is, however, limited to the seating capacity of the room.

Self-Assessment Program

The 1981 Self-Assessment Program will be offered Monday, Tuesday, and Wednesday from 8:00 a.m. to 5:00 p.m., and Thursday from 8:00 a.m. to 12:00 Noon. The program will require 50 minutes.

"MEET THE EXPERTS"

These workshops provide a forum for person-to-person discussion of a variety of cardiovascular problems. Registration is limited for each Meet the Experts group. **Admission is by ticket only,** therefore, early reservation of the Meet the Experts tickets is advisable. The Advance Registration Form provides for the reservation of choice. Participants are assumed to have a basic understanding of the topics discussed at the workshops and are encouraged to bring applicable tracings or problems for group discussion.

Monday, March 16

Group I	10:30 a.m.–11:30 a.m.
Group I	2:30 p.m.–3:30 p.m.
Group II	4:00 p.m.–5:00 p.m.

Tuesday, March 17

Group I	9:00 a.m.–10:00 a.m.
Group II	10:30 a.m.–11:30 a.m.
Group I	2:30 p.m.–3:30 p.m.
Group II	4:00 p.m.–5:00 p.m.

Wednesday, March 18

Group I	9:00 a.m.–10:00 a.m.
Group II	10:30 a.m.–11:30 a.m.
Group I	2:00 p.m.–3:00 p.m.

Thursday, March 19

Group I	9:00 a.m.–10:00 a.m.
Group II	10:30 a.m.–11:30 a.m.

Technical and Scientific Exhibits

More than 500 exhibits will be featured at the 30th Annual Scientific Session. The 1981 exhibits are designed to update the physician's knowledge of products and research and they deserve the attention of all physicians and scientists in attendance. Exhibit hours are:

Date	Hours
Monday, March 16	9:00 a.m.–5:00 p.m.
Tuesday, March 17	9:00 a.m.–5:00 p.m.
Wednesday, March 18	9:00 a.m.–5:00 p.m.
Thursday, March 19	9:00 a.m.–12:00 Noon

Transportation

Shuttle bus service will be provided at regular intervals for all registrants to and from the San Francisco Civic Auditorium and all hotels in the official College commitment. Schedules and routes will be posted in the main lobbies of all hotels within the College commitment and will also be listed in the final program.

Joggers

There will be a jogging tour led by Past President Henry D. McIntosh, MD, FACC, come rain or shine on Monday, Tuesday, and Wednesday mornings. Departure will be at 6:30 a.m. from the Union Square entrance to the St. Francis Hotel.

At 7:00 a.m., there will be a cool-down continental breakfast served in the California East Room of the St. Francis. We look forward to seeing you each of the three days.

Fellowship Candidates

Fellows who are to be inducted at the 1981 Convocation will receive separate instructions. Please remember that you must sign the Convocation Register prior to 10:00 a.m. on Wednesday, March 18, 1981. The Register will be located on the second floor of Civic Auditorium.

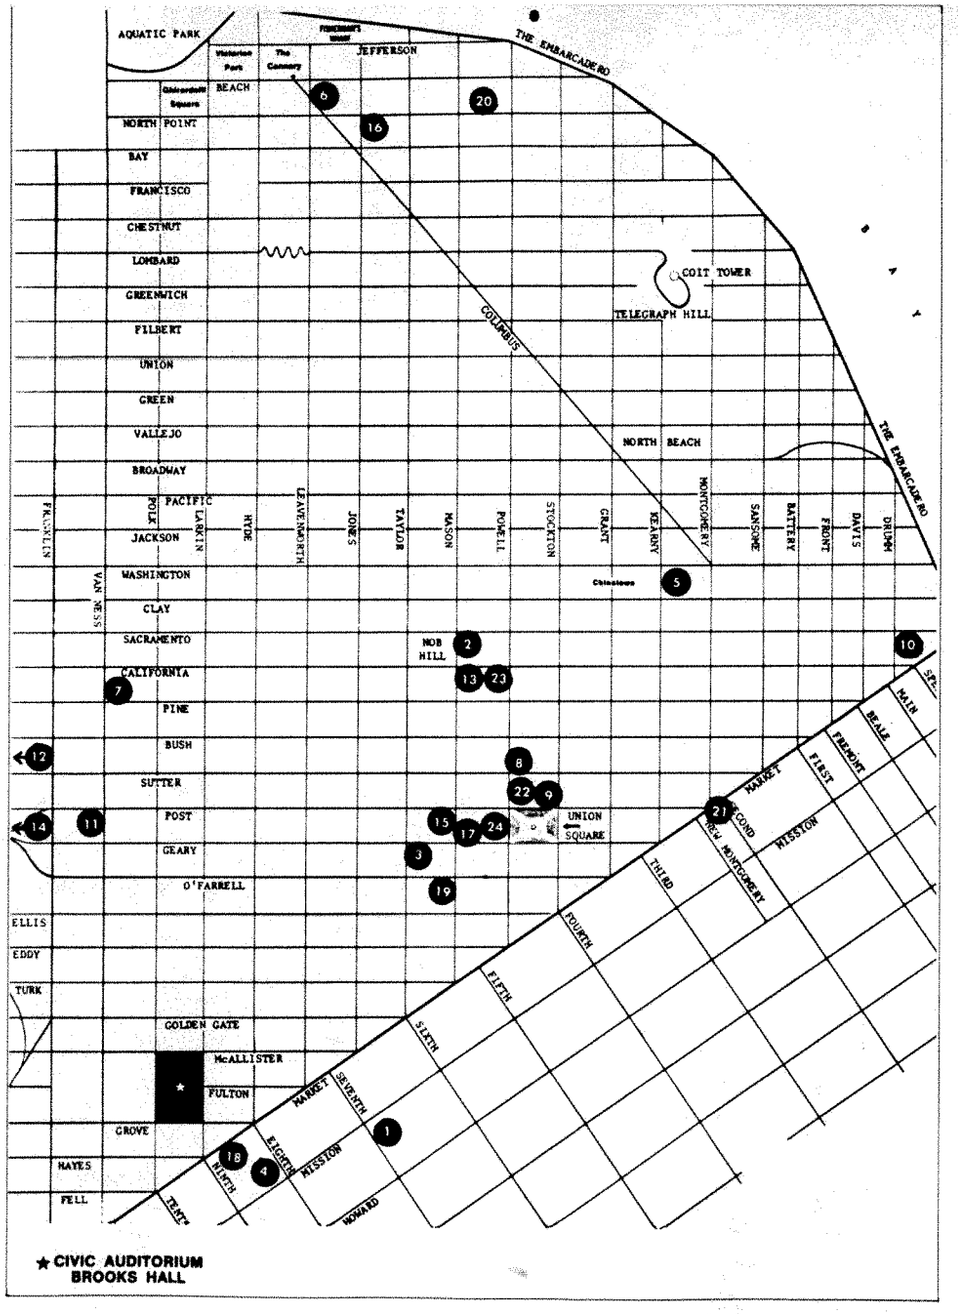
Application for Hotel Accommodations

A map and application form for hotel accommodations are shown on pages 384 and 385. Please note:

1. The form must be received by the Housing Bureau **no later than February 12** to ensure receipt of a written confirmation.
2. **After February 12,** the Housing Bureau may be contacted directly to determine availability of rooms. After contacting the Bureau at 415 626-5500, you must then contact the hotel directly to make your reservation.

For more information contact:

Ellen Nitzberg, Assistant Director
Annual Scientific Session Department
American College of Cardiology
9111 Old Georgetown Road
Bethesda, Maryland 20014
(301 897-5400).



The following are hotels in San Francisco, where reservations are available. Please refer to number and map for location.

MAP LOC	HOTEL	SINGLES	DOUBLES/ TWINS	SUITES

*A guaranteed reservation will be held for late arrival. However, you will pay for the first night's lodging even if you do not occupy the room — UNLESS you cancel your reservation 24 hours in advance.

CALENDAR OF EXTRAMURAL PROGRAMS

The aim of each program is to increase the theoretical and practical knowledge of the normal and abnormal function of the cardiovascular system in man. Most of the programs are pertinent to direct care of patients with heart disease. The need for such programs increases with the ever increasing amount of scientific and clinical data, the constant changes in technology and methodology, and the greater availability of therapeutic options. Today most cardiologists, internists and family practitioners feel the need of supplementing their professional reading by direct contact with the authors, research workers and leaders in the field.

To solve these problems the Committee selects each year series of carefully supervised programs which are usually preceded by extensive consultations with the program directors recruited among the foremost specialists educators and scientists in the field of clinical cardiology and allied basic science disciplines.

Although each program director is personally responsible for the choice of faculty, and the structure of the program, the Continuing Education Committee for Extramural Programs assumes the overall responsibility for the caliber of the postgraduate education and the relevance to the practice of cardiology. This is accomplished by the processes of meticulous scrutiny of the objectives, analysis of the educational methods, and studying the impact of each course on the knowledge and attitudes of the participants.

These programs should help each physician to keep up with the new knowledge, to put into practice the new advances and to retract gracefully from the obsolete and useless practices. An effective practitioner must learn and relearn, listen to new ideas, share past experiences and observe the work of his peers. The Continuing Education Committee for Extramural Programs of the American College of Cardiology believes that these goals can be accomplished by all members and nonmember professionals participating in our continuing education programs.

Leonard S. Dreifus, MD, FACC
Chairman, Continuing Education Committee for Extramural Programs

Programs and faculty are subject to change. For further information write Registration Secretary, Extramural Programs Department, American College of Cardiology, Heart House, 9111 Old Georgetown Road, Bethesda, Maryland 20014.

FEBRUARY THROUGH AUGUST 1981

1981

To be arranged individually — **Preceptorships in Cardiology.** Arthur Selzer, FACC, director, Pacific Medical Center, San Francisco, CA

To be arranged individually — **Preceptorships in Cardiology.** Jules Constant, FACC, director. Buffalo General Hospital, Buffalo, NY

FEB. 2–4 — **Clinical Echocardiography 1981—M-Mode, 2-Dimensional and Pulsed Doppler Techniques,** Pravin M. Shah, FACC, director and John S. Child, FACC, Joseph K. Perloff, FACC, and Maylene Wong, co-directors. Sheraton Harbor Island Hotel, San Diego, CA

FEB. 9–11 — **Calcium (Slow Channel)-Inhibiting Drugs in Cardiovascular Therapy: Mechanism of Action and Application.** Borys Surawicz, FACC and Attilio Maseri, FACC, directors. New Orleans Marriott, New Orleans, LA

FEB. 19–20 — **Ventricular Arrhythmias and Sudden Cardiac Death.** Thomas B. Graboys, FACC and Bernard Lown, FACC, directors. Sheraton Boston Hotel, Boston, MA

MAR. 30–APR. 3 — **Electrocardiographic Interpretation of Complex Arrhythmias: A Physiological Approach.** Charles Fisch, FACC and Douglas P. Zipes, FACC, directors. Krannert Institute of Cardiology, Indiana University Medical Center, Indianapolis, IN

APR. 6–15 — **Cardiology for the Consultant: A Clinician's Retreat.** E. Grey Dimond, FACC and James E. Crockett, FACC, directors. Rancho Santa Fe Inn, Rancho Santa Fe, CA

APR. 16–18 — **New Diagnostic and Therapeutic Modalities in Cardiology.** Edmund H. Sonnenblick, FACC and James Scheuer, FACC, directors. Grand Hyatt New York, New York, NY

APR. 23–24 — **Contemporary Phonocardiography (With Echocardiographic Correlation).** Morton E. Tavel, FACC, director. Methodist Hospital, Indianapolis, IN

APR. 27–MAY 1 — **Consultant's Course in Cardiology.** Richard Gorlin, FACC, Louis E. Teichholz, FACC, Simon Dack, FACC and Ephraim Donoso, FACC, directors. Mount Sinai Medical Center, New York, NY

APR. 29–MAY 1 — **Vectorcardiography—An Advanced Workshop.** Alberto Benchimol, FACC, director. Scottsdale Hilton Hotel, Scottsdale, AZ

MAY 7–9 — **The Pathology of Acquired Diseases of the Heart and Conduction System.** Jesse E. Edwards, FACC, Maurice Lev, FACC and Saroja Bharati, FACC, directors. Radisson Hotel, St. Paul, MN

MAY 7–9 — **Cardiac Emergencies.** Arthur Selzer, FACC and Richard Pasternak, co-directors. The Mark Hopkins, San Francisco, CA

MAY 7–9 — **Practical Cardiology for the Primary Care Physician,** Leonard S. Dreifus, FACC and Joel Morganroth, FACC, directors. Sarasota Hyatt Hotel, Sarasota, FL

MAY 13–15 — **Clinical Auscultation of the Heart.** W. Proctor Harvey, FACC, director and Antonio C. de Leon, Jr., FACC and John F. Stapleton, co-directors. Gorman Building Auditorium, Georgetown University Medical Center, Washington DC

MAY 14–16 — **Cardiac Diagnostic Techniques—A Clinical Perspective.** Arnold M. Weissler, FACC and Nicholas Z. Kerin, FACC, directors and Franklin E. Hull, FACC, S. C. Khullar, FACC and Melvin Rubenfire, FACC, co-directors. Detroit Plaza Hotel, Renaissance Center, Detroit, MI

MAY 18–22 — **Modern Cardiology.** J. Willis Hurst, FACC and Robert C. Schlant, FACC, directors. Sheraton Atlanta Hotel, Atlanta, GA

MAY 28–31 — **Sixth Annual Symposium on Cardiovascular Nursing.** Henry J. L. Marriott, FACC and Leo Schamroth, FACC, directors. Sheraton Sand Key Hotel, Clearwater Beach, FL

JUNE 17–19 — **The Patient with Arrhythmia—A Clinical Approach.** Ross D. Fletcher, FACC and W. Proctor Harvey, FACC, directors. Gorman Building Auditorium, Georgetown University Medical Center, Washington, DC

JUNE 30–JULY 3 — **Eighth Annual Symposium on Clinical Echocardiography: Current Applications and New Developments.** Arthur D. Hagan, FACC, director and Anthony N. DeMaria, FACC and William F. Friedman, FACC, co-directors. Snowbird Conference Center, Snowbird Ski and Summer Resort, Snowbird, UT

AUG. 29–31 — **Tutorials in the Tetons: Clinical Cardiology: Diagnostic and Therapeutic Advances (Seventh Annual).** Robert S. Eliot, FACC, director and James C. Buell, Timothy Fleming, FACC and Gerald L. Wolf, co-directors. Jackson Lake Lodge, Moran, WY

EARNING CENTER: PROGRAM CALENDAR

The American College of Cardiology's Learning Center is located at the College's headquarters in Bethesda, Maryland. The purpose of the Learning Center is to support professional commitment to quality patient care by providing a standard of excellence in continuing medical education.

For additional information or a complete program calendar, contact the Program Registrar, Heart House Learning Center, American College of Cardiology, 9111 Old Georgetown Road, Bethesda, Maryland 20014. Telephone (301) 897-5400.

LEARNING CENTER PROGRAMS: FEBRUARY to JULY 1981

Program Number	Date	Program Director	Title of Program
334	February 5–6	August M. Watanabe, MD	Fundamental Cardiac Biochemistry for the Cardiologist

329	June 15–17	Robert A. O'Rourke, MD	Detection of Cardiac Disease by Physical Examination
302	June 22–24	Paul C. Gillette, MD	Decisions in Clinical Pediatric Cardiac Surgery
331	June 29–30, July 1	B. Leonard Holman, MD	Nuclear Cardiology
330	July 8–10	Michael R. Rosen, MD	Clinical Pharmacology and Electrophysiology of Antiarrhythmic Drugs

IN MEMORIAM: MARIANO ALIMURUNG, MD, FACC

On Sunday night, November 16 or Monday morning, November 17, a man was murdered in his hotel room by strangulation by a thief. That story and similar madness can be found in each day's news. This man was a special friend, not only of myself but of the United States, of international medicine and cardiology, of the American College of Cardiology, and all who knew him. He was Dr. Mariano Alimurung from The Philippines, in the United States as he has been so many times for heart meetings, this time the annual meeting of the American Heart Association in Miami, Florida. On the last evening of his life, he had dinner with old friends, Dr. and Mrs. Louis Lemberg, returned to his hotel and, it is assumed, surprised someone ransacking his room and was killed, defending himself.

Dr. Alimurung was trained by Paul White and was first here in the United States in 1947. He was the first governor for the College in The Philippines and the host of the College's first circuit course. In 1973 Dr. Alimurung was made a Distinguished Fellow of the College. His affection for this country and its people brought him here yearly, and hundreds of us have been under his vigorous guidance in Manila. Vigorous is the only way to describe the happy, wholehearted, gracious enthusiasm with which he took over the management of one's visit.

The utter meanness that ended the life of this friend of Americans is awful. No logic, no imagination, no justification can make clear why this special man had to lose his life while carrying on one more act of the medical ambassadorship which he made his life's work. Mariano Alimurung was equally a citizen of both countries and few physicians were such complete internationalists. The sorrow in his passing is a sorrow felt by men and women of cardiology in every nation. A fitting farewell to him does not need to list degrees, honors, awards, officerships, academic posts, editorships and papers, for all who read these notes have their special memory of the very human qualities that made Mariano the unusual man he was.

Dr. Alimurung **(left)** *with Past College Presidents Eliot Corday* **(center)** *and E. Grey Dimond* **(right).**

To his wife Natividad and to their children and to his colleagues in The Philippines, we Americans send a message of profound grief, sympathy and, above all, an apology for his unjust end on American soil.

E. Grey Dimond, MD, FACC

CARDIOLOGY BOARD REVIEW: Update in Cardiology

September 9–11, 1981 **Atlanta, Georgia**

Presented by: The American College of Cardiology

Directors: **J. WILLIS HURST, MD, FACC and ROBERT C. SCHLANT, MD, FACC**

For brochure and further information contact: Registration Secretary, Extramural Programs Department, American College of Cardiology, 9111 Old Georgetown Road, Bethesda, Maryland 20014. Telephone: Area Code 301 897-5400

Take a close look at Compu-Scan
The future in Holter Technology

inaccuracy of first and
ond generation Holter
opic Counters is legend.
se analog-based voltage
asurements have proven so
ccurate in fact that most
rs preferred to disbelieve the
opic counters and count on
ir own visual identification of
normal beats.

ut now there's Compu-scan
he eye that never looks away.
ew generation in Holter
ems, Compu-scan utilizes
icrocomputer to build in
mory an average or typical
nplex for each patient.
"normal" is constantly up-
ed as the patient's activity
anges. In microseconds,
computer makes all of the calculations on each new QRS complex that the human mind would take minutes to determine. It's a quantum leap ahead in ectopic beat recognition . . . both in speed and accuracy.

- Only Compu-scan can scan tapes produced on virtually any Holter recorder, cassette, reel to reel, direct recording or FM.
- The large 15" monitor provides over a minute of ECG on the screen at one time, plus up to 512 seconds in memory.
- Complete summary reports and graphics are produced on Compu-scan's high speed line printer while summary graphs and reports are displayed in color on the Color-graphics display.
- Modular in design, Compu-scan can be incorporated into your facility a step at a time as your needs dictate. Take a close look at Compu-scan and you'll see the future in Holter technology.

For the complete Compu-Scan brochure, call us toll free, 800-638-2896.

The Agony and the Ecstasy and the Agony of installing your own Holter System.

The Agony.

Seemed like a good idea. Your very own Holter System. Right there in the hospital. Then you shopped around.

What you found was an easy way to get lost. Umpteen totally different models. Endless claims and testimonials. And more miracles of modern technology than there are gas guzzlers on America's used car lots. And not one decent, long-running track record in the bunch.

The Ecstasy.

But you hung in there. Took some chances and made a few guesses. And chose the spiffiest new model with the most splendiferous features you could find. How could it ever be obsolete? Buttons by the dozen. Dials, screens, and keyboards. And more switches, levers, lights, meters, buzzers and whistles than you'll ever know what to do with.

You were *so* happy when it arrived.

And the Agony.

Now all you had to do was find a bit of space for it—well, maybe a little more. And train a technician or two to operate it—if you could find them.

Then there was that financing (what financing?). Maybe up to seventy thousand dollars worth? And the interest—at rates known as usury in Biblical times. Oh, and salaries for the nurses and technicians.

Not to mention maintenance. The down time. What to *do* when it's down. What to do when the *staff* is down, or on strike, or. . . , or whatever!

The Alternative.

After all this, one begins to realize that what was really wanted was, not gadgets, gizmos, lights, dials, and whistles—but *information*. Accurate data. Clearly reported. The kind of well documented, intelligently presented, quantitated data you get with every Clinical Data LCG Report.

Even if you've seen one of Clinical Data's LCG Reports, you haven't really seen one of Clinical Data's *new* LCG Reports. We've made the best even better. Call or write. We'll send you one.

Introducing the
of Interrogatable

Programalith® 6 is the full six-parameter interrogatable, programmable pacemaker. In conjunction with the Programmer, Programalith 6 provides the physician with

- the means for comprehensive paced-patient management
- while obviating many common reasons for invasive pacing system revision.

For less critical applications, Programalith 3 provides the physician with the same basic interrogation capabilities as Programalith 6, as well as three programming functions – pacing rate, pulse width and sensitivity – all with multiple options.

Only after you have reached the ultimate in sophistication can you truly simplify This new 6-3-1-0 family of Programalith® Interrogatable™ pacemakers is idea demonstration of that fact. It is the most flexible system ever offered the physician Even the simplest of these four pulse generators offers the all-important Pacesette exclusive: a simple method of calculating years of remaining battery capacit as well as an accurate determination of possible problems and their location through measurement by interrogation of lead and heart interface impedance

Complete Family Pacemakers.

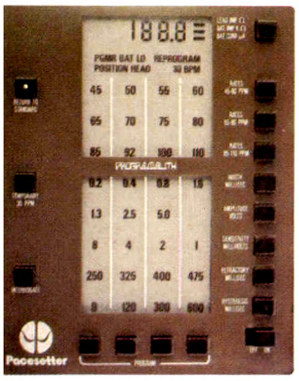
Programalith 1 interrogates and programs a single parameter – pacing rate – allowing the physician to choose from 12 different options and provides the all-important interrogation function as well.

For simplest applications, Programalith 0 requires no programming, yet can still be interrogated for all measured data, providing invaluable assistance in long term patient management.

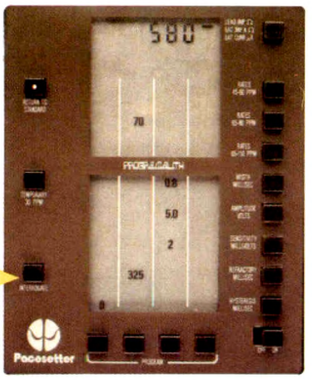
ttery impedance and battery current. Part of the exibility of this new system derives from the mplete integration of all units with the one single rogrammer the physician will ever need – e one Pacesetter supplies to you with the first nplant of any one of these pacers. o wonder they call us Pace*setter*.

Pacesetter speaks your language.

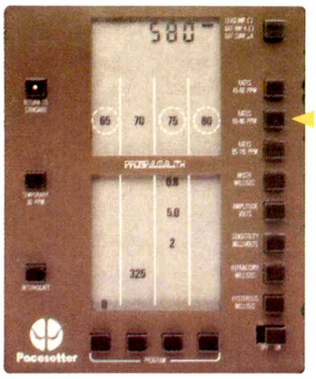
6310



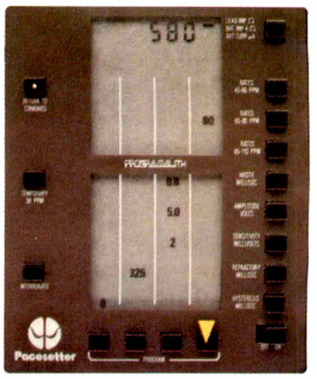
urn on the programmer. The display creen flashes and then fully illumi- ates as the programmer performs a ystem self-check.



Press "Interrogate" button. Telemetry confirmation of programmed settings and measured data will appear on the display screen.



Any individual parameter may be selected for change. Press the button next to the desired parameter. The programmable alternatives will flash.



Effect programming by pressing the "Program" button directly below the appropriate column. When confirming telemetry is received, the new value will be displayed.

With Programalith you can determine all parameters affecting pacemaker performance and optimize the system to best satisfy the patient's needs while extending service life.

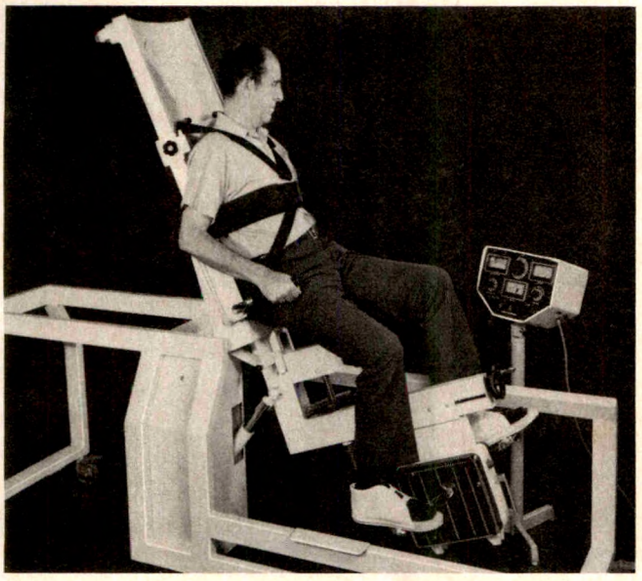
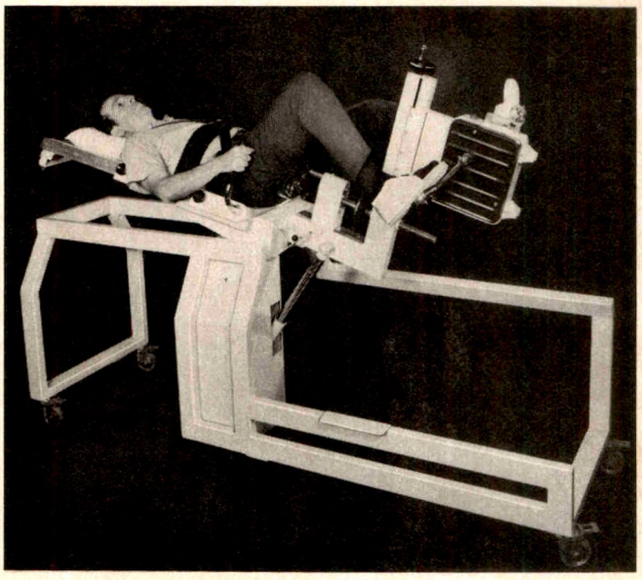
UPRIGHT SUPINE

Get BOTH...and all positions between



Erect stress test position.



Supine stress test position. Far side of table is unobstructed to easily accommodate a gamma camera.

With this
Nuclear Cardiology Stress System*

- **Motorized patient positioning.**
- **Compatible with all cameras.**
- **Motion-free for high resolution.**
- **Converts to standard imaging table.**

Here is the most versatile, easy-to-operate, stress imaging table available. It permits radionuclide imaging under stress in ANY position, from supine to upright. Just flip a switch, and the patient is moved effortlessly to the desired position. Unlike with other stress tables, you are not restricted to supine imaging.

Whatever your nuclear cardiology requirements, this unique system fills them quickly and easily...full gamma camera clearance, complete mobility, motion-free stability, positive (but comfortable) patient restraints, unobstructed access to the patient and controls, choice of Collins or Quinton ergometers, and much more. The unit can even be used for conventional imaging.

Send for full details.

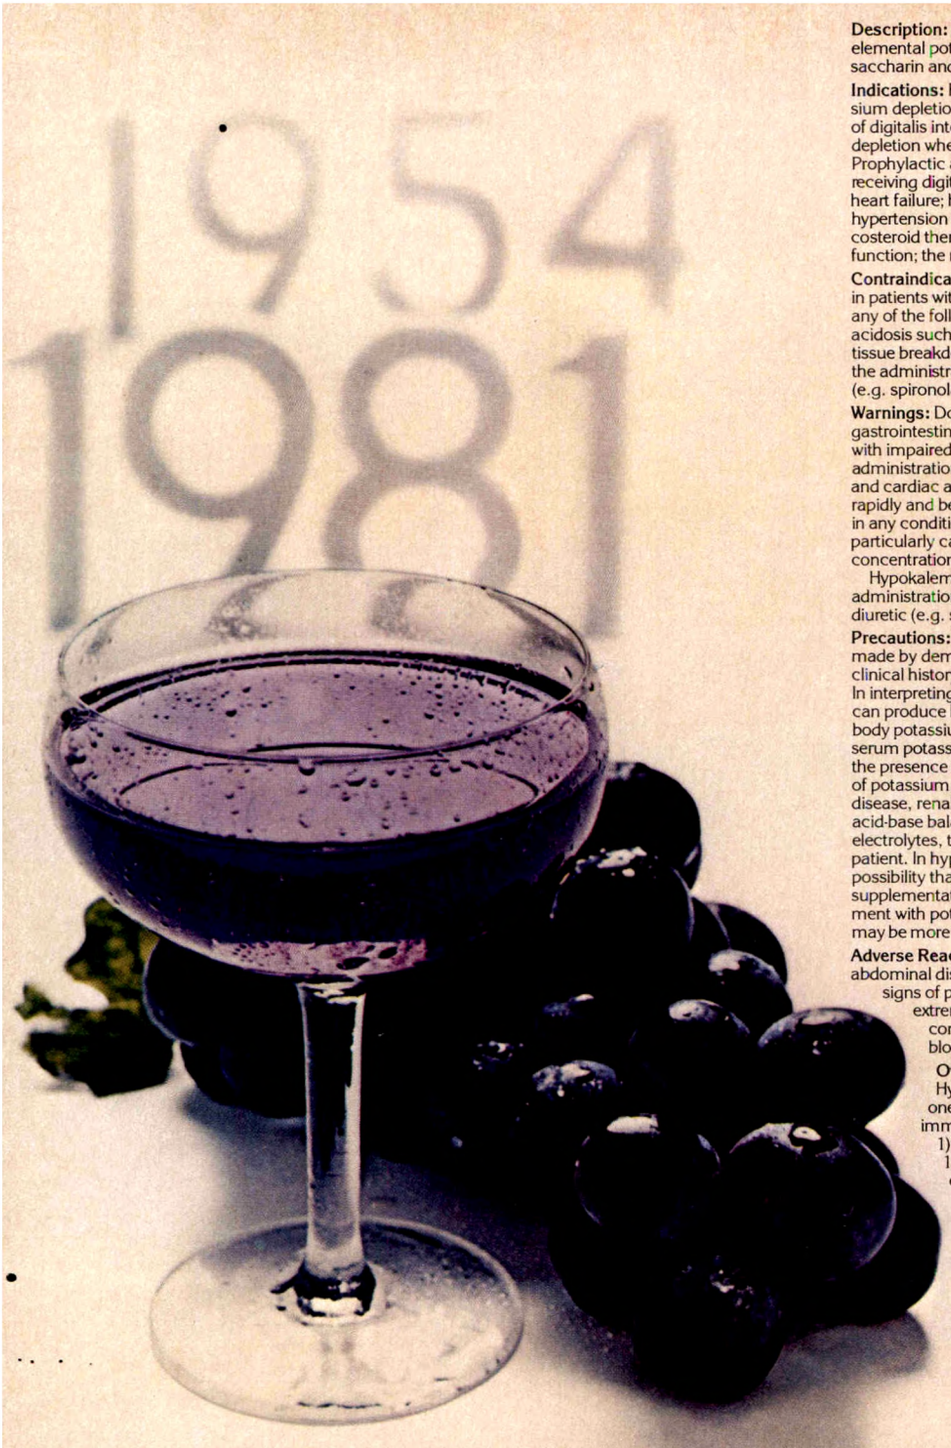
VICTOREEN
NUCLEAR ASSOCIATES
100 Voice Road
Carle Place, N.Y. 11514
(516) 741-6360

VICTOREEN

*Patent Pending



Description: Each 15 ml (tablespoonful) supplies 20 mEq of elemental potassium (as potassium gluconate, 4.68 g) with saccharin and aromatics. Alcohol 5%.

Indications: Kaon Elixir is indicated for the treatment of potassium depletion in patients with hypokalemia, for the treatment of digitalis intoxication, and for the prevention of potassium depletion when the dietary intake of potassium is inadequate. Prophylactic administration may be indicated in patients receiving digitalis and diuretics for the treatment of congestive heart failure; hepatic cirrhosis with ascites; patients with hypertension on long-term diuretic therapy; patients on corticosteroid therapy; hyperaldosteronism states with normal renal function; the nephrotic syndrome; and certain diarrheal states.

Contraindications: Potassium supplements are contraindicated in patients with hyperkalemia. Hyperkalemia may complicate any of the following conditions: Chronic renal failure, systemic acidosis such as diabetic acidosis, acute dehydration, extensive tissue breakdown as in severe burns, adrenal insufficiency, or the administration of a potassium-sparing diuretic (e.g. spironolactone, triamterene).

Warnings: Do not administer full strength. Kaon Elixir may cause gastrointestinal irritation if administered undiluted. In patients with impaired mechanisms for excreting potassium, the administration of potassium salts can produce hyperkalemia and cardiac arrest. Potentially fatal hyperkalemia can develop rapidly and be asymptomatic. The use of potassium salts in any condition which impairs potassium excretion requires particularly careful monitoring of the serum potassium concentration and appropriate dosage adjustment.

Hypokalemia should not be treated by the concomitant administration of potassium salts and a potassium-sparing diuretic (e.g. spironolactone or triamterene).

Precautions: The diagnosis of potassium depletion is ordinarily made by demonstrating hypokalemia in a patient with a clinical history suggesting some cause for potassium depletion. In interpreting the serum potassium level, acute alkalosis per se can produce hypokalemia in the absence of a deficit in total body potassium, while acute acidosis per se can increase the serum potassium concentration into the normal range even in the presence of a reduced total body potassium. The treatment of potassium depletion, particularly in the presence of cardiac disease, renal disease, or acidosis, requires careful attention to acid-base balance and appropriate monitoring of serum electrolytes, the electrocardiogram, and the clinical status of the patient. In hypokalemic states, hypochloremic alkalosis is a possibility that may require chloride as well as potassium supplementation. In these circumstances, potassium replacement with potassium chloride (e.g. Kaochlor 10% Liquid, W-T) may be more advantageous than with other potassium salts.

Adverse Reactions: Nausea, vomiting, diarrhea, and abdominal discomfort have been reported. The symptoms and signs of potassium intoxication include paresthesias of the extremities, flaccid paralysis, listlessness, mental confusion, weakness and heaviness of the legs, fall in blood pressure, cardiac arrhythmias, and heart block.

Overdosage and Treatment of Hyperkalemia: Hyperkalemia can occur from overdosage or during one of several medical conditions. It should be treated immediately by one or more of the following: 1) Intravenous administration of 300 to 500 ml/hr of 10% dextrose solution containing 10-20 units of crystalline insulin per 1,000 ml. 2) administration of sodium or ammonium cycle exchange resins orally or as retention enemas; 3) hemodialysis or peritoneal dialysis; 4) elimination of potassium containing foods. Caution: Digitalis toxicity can occur if the serum potassium is lowered too rapidly.

How Supplied: Pints and gallons in Grape and Lemon-Lime flavors; 15 ml Stat-Pak and 4 fl. oz. in Grape flavor only.

Vintage potassium that's always in good taste.

Kaon® Elixir
(potassium gluconate)
20 mEq per 15 ml

Pleasant tasting grape or lemon-lime flavors
Prescribed with confidence for 26 years

- Well accepted—good patient tolerance
- One tbsp. in 1 oz or more of water supplies 20 mEq potassium (as gluconate)

Laragh's eagerly awaited new book on the silent killer

TOPICS IN HYPERTENSION

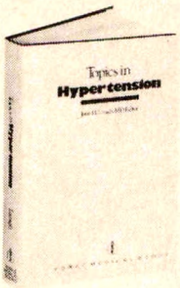
Just published!

High blood pressure is no longer only a problem of worldwide interest and relevance. It is now one in which the knowledge base has exploded to the point where the informed physician can do more and more about it in his daily practice...and can apply, to an ever-increasing extent, more sophisticated and individually tailored therapies.

Laragh's TOPICS IN HYPERTENSION places this kind of vital knowledge within instant reach of the physician. It presents a carefully selected array of discussions. It deals in depth with recent breakthroughs in understanding, diagnosing, and treating this problem.

This book is conveniently organized for effective consultation and reading:

- **Section 1** considers recently maturing biochemical and pathophysiologic aspects of the problem.
- **Section 2** deals with new physiologic approaches to diagnosis.
- **Section 3** discusses new perceptions of the clinical and prognostic aspects of hypertension.
- **Section 4** considers in detail the more recently introduced modes of therapy. These new agents presage the beginning of a new era of more selective and specific therapy for increasing numbers of patients.



Edited by

John H. Laragh, MD

Master Professor of Medicine Director, The Cardiovascular Center Chief, Cardiology Division The New York Hospital-Cornell Medical Center

644 pages. 36 chapters by 85 internationally known specialists. Illustrated. Comprehensively indexed. $49.00. Available on 30-day approval.

To reduce the risk of potentially fatal arrhythmias in patients with compromised hearts

Quinaglute® 324 mg DURA-TABS®

(quinidine gluconate)

- Practical b.i.d. or t.i.d. dosage protects night and day
- Less frequent administration helps improve patient compliance and thus helps assure needed round-the-clock protection.[2]

Danger! PVC's don't sleep!

324 mg
Quinaglute®
DURA-TABS®
(quinidine gluconate)

CONTRAINDICATIONS:
Aberrant impulses and abnormal rhythms due to escape mechanisms should not be treated with quinidine.

Partial A-V or complete heart block, or intraventricular conduction defects, especially those exhibiting a marked grade of QRS widening.

Renal disease resulting in significant azotemia, or those developing cardiotoxic effects such as conduction defects, ventricular premature beats, ventricular tachycardia or flutter while on the drug.

Marked cardiac enlargement, particularly with congestive failure, poor renal function, and especially renal tubular acidosis.

Idiosyncrasy or hypersensitivity to quinidine.

WARNINGS:
In the treatment of atrial flutter, reversion to sinus rhythm may be preceded by a progressive reduction in the degree of A-V block to a 1:1 ratio resulting in an extremely rapid ventricular rate.

PRECAUTIONS:
The precautions to be observed include all those applicable to quinidine. A preliminary test dose of a single tablet of quinidine sulfate should be administered to determine if the patient has an idiosyncrasy to quinidine. Hypersensitivity to quinidine, although rare, should constantly be considered, especially during the first weeks of therapy.

Quinidine in large doses may reduce the contractile force of the heart, therefore, extreme caution should be exercised in using the drug in patients with severe heart disease, hypotension or digitalis intoxication. The potential disadvantages and benefits must be weighed.

It should be administered cautiously, if at all, to senile patients.

Hospitalization for close clinical observation, electrocardiographic monitoring, and possibly plasma quinidine levels is indicated when large doses are used or with patients who present an increased risk.

ADVERSE REACTIONS:
Symptoms of cinchonism, ringing in ears, headache, nausea, disturbed vision may appear in sensitive patients after a single dose of the drug.

Cardiovascular: Widening of QRS complex, cardiac asystole, ventricular ectopic beats, idioventricular rhythms including ventricular tachycardia and fibrillation, paradoxical tachycardia, arterial embolism, hypotension.

Gastrointestinal: Nausea, vomiting, abdominal pain, diarrhea.

Hematologic: Acute hemolytic anemia, hypoprothrombinemia, thrombocytopenic purpura, agranulocytosis.

Central Nervous System: Headache, fever, vertigo, apprehension, excitement, confusion, delirium and syncope, disturbed hearing (tinnitus, decreased auditory acuity), disturbed vision (mydriasis, blurred vision, disturbed color perception, reduced vision fields, photophobia, diplopia, night blindness, scotomata), optic neuritis.

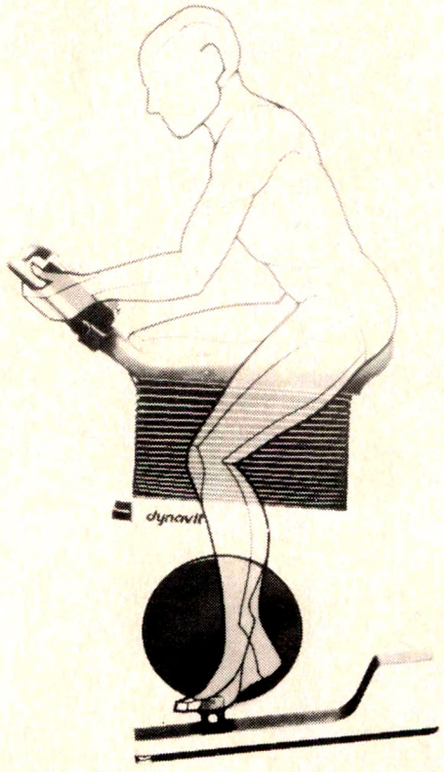
Dermatologic: Cutaneous flushing with intense pruritus.

Hypersensitivity Reactions: Angioedema, acute asthmatic episode, vascular collapse, respiratory arrest.

See package insert for full information.

BERLEX Laboratories Inc.
Cedar Knolls, New Jersey 07927

A dynamometer which measures physical work rates



Now with the new series of Dynavit equipment, graded exercise is possible on an ergometer with its own built-in calibrating dynamometer. Controlled pulses of current are fed through electrical windings of the braking system and a magnetic field is induced which becomes the braking torque to oppose the flywheel's rotation. The braking system is float mounted such that it responds in a counter torsion movement, and this is mechanically transmitted into a precision strain gauge.

And a phototachometer accurately counts the flywheel revolutions per minute. Therefore, the true and effective cranking effort (work rate = watts of power expended) is dynamometrically controlled. **Constant, calibrated and controlled work rates independent of pedal speed!**

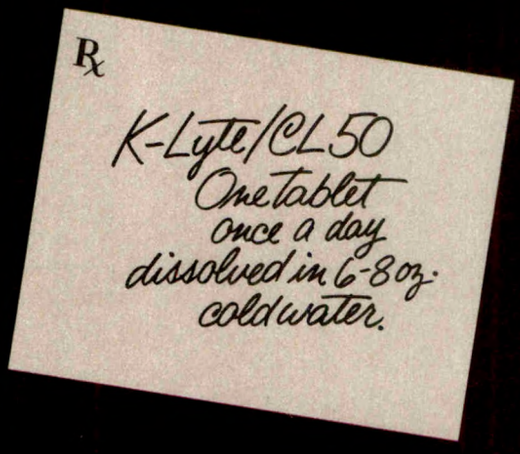
mEq potassium chloride

he nce-a-day otassium hloride upplement

uit punch and citrus flavors



VESCENT TABLETS
E/CL® 50 mEq—Fruit Punch and Citrus Flavors
(effervescent tablet in solution supplies 50 mEq potassium chloride)

CRIBING CONSIDERATIONS

ATIONS: K-LYTE/CL 50 mEq is an oral potassium supplement for therapy or prophylaxis of potassium deficiency. It is particularly useful when e diuretics, corticosteroids, or severe vomiting and diarrhea cause excessive excretory potassium losses, and when dietary potassium is low. lly monitored, K-LYTE/CL 50 mEq may also be useful for potassium administration where digitalis intoxication results in cardiac arrhythmias.

RAINDICATIONS: Impaired renal function with oliguria or azotemia, Addison's disease, hyperkalemia from any cause.

INGS AND PRECAUTIONS: Since the amount of potassium deficiency may be difficult to determine accurately, supplements should be admin- with caution, and dosage adjusted to the requirements of the individual patient. Potassium intoxication rarely occurs in patients with normal function. Symptoms of potassium intoxication are variable. They include listlessness, mental confusion, and tingling of the extremities. Fre- checks of the clinical status of the patient, ECG, and serum potassium level are desirable. In established hypokalemia, attention should also ected toward other potential electrolyte disturbances. Potassium supplements should be given cautiously to digitalized patients and such ts should be monitored by ECG for cardiac irregularities. To minimize the possibility of gastrointestinal irritation associated with the oral inges- concentrated potassium salt preparations, **patients should be carefully directed to dissolve each dose completely in the stated nt of water.**

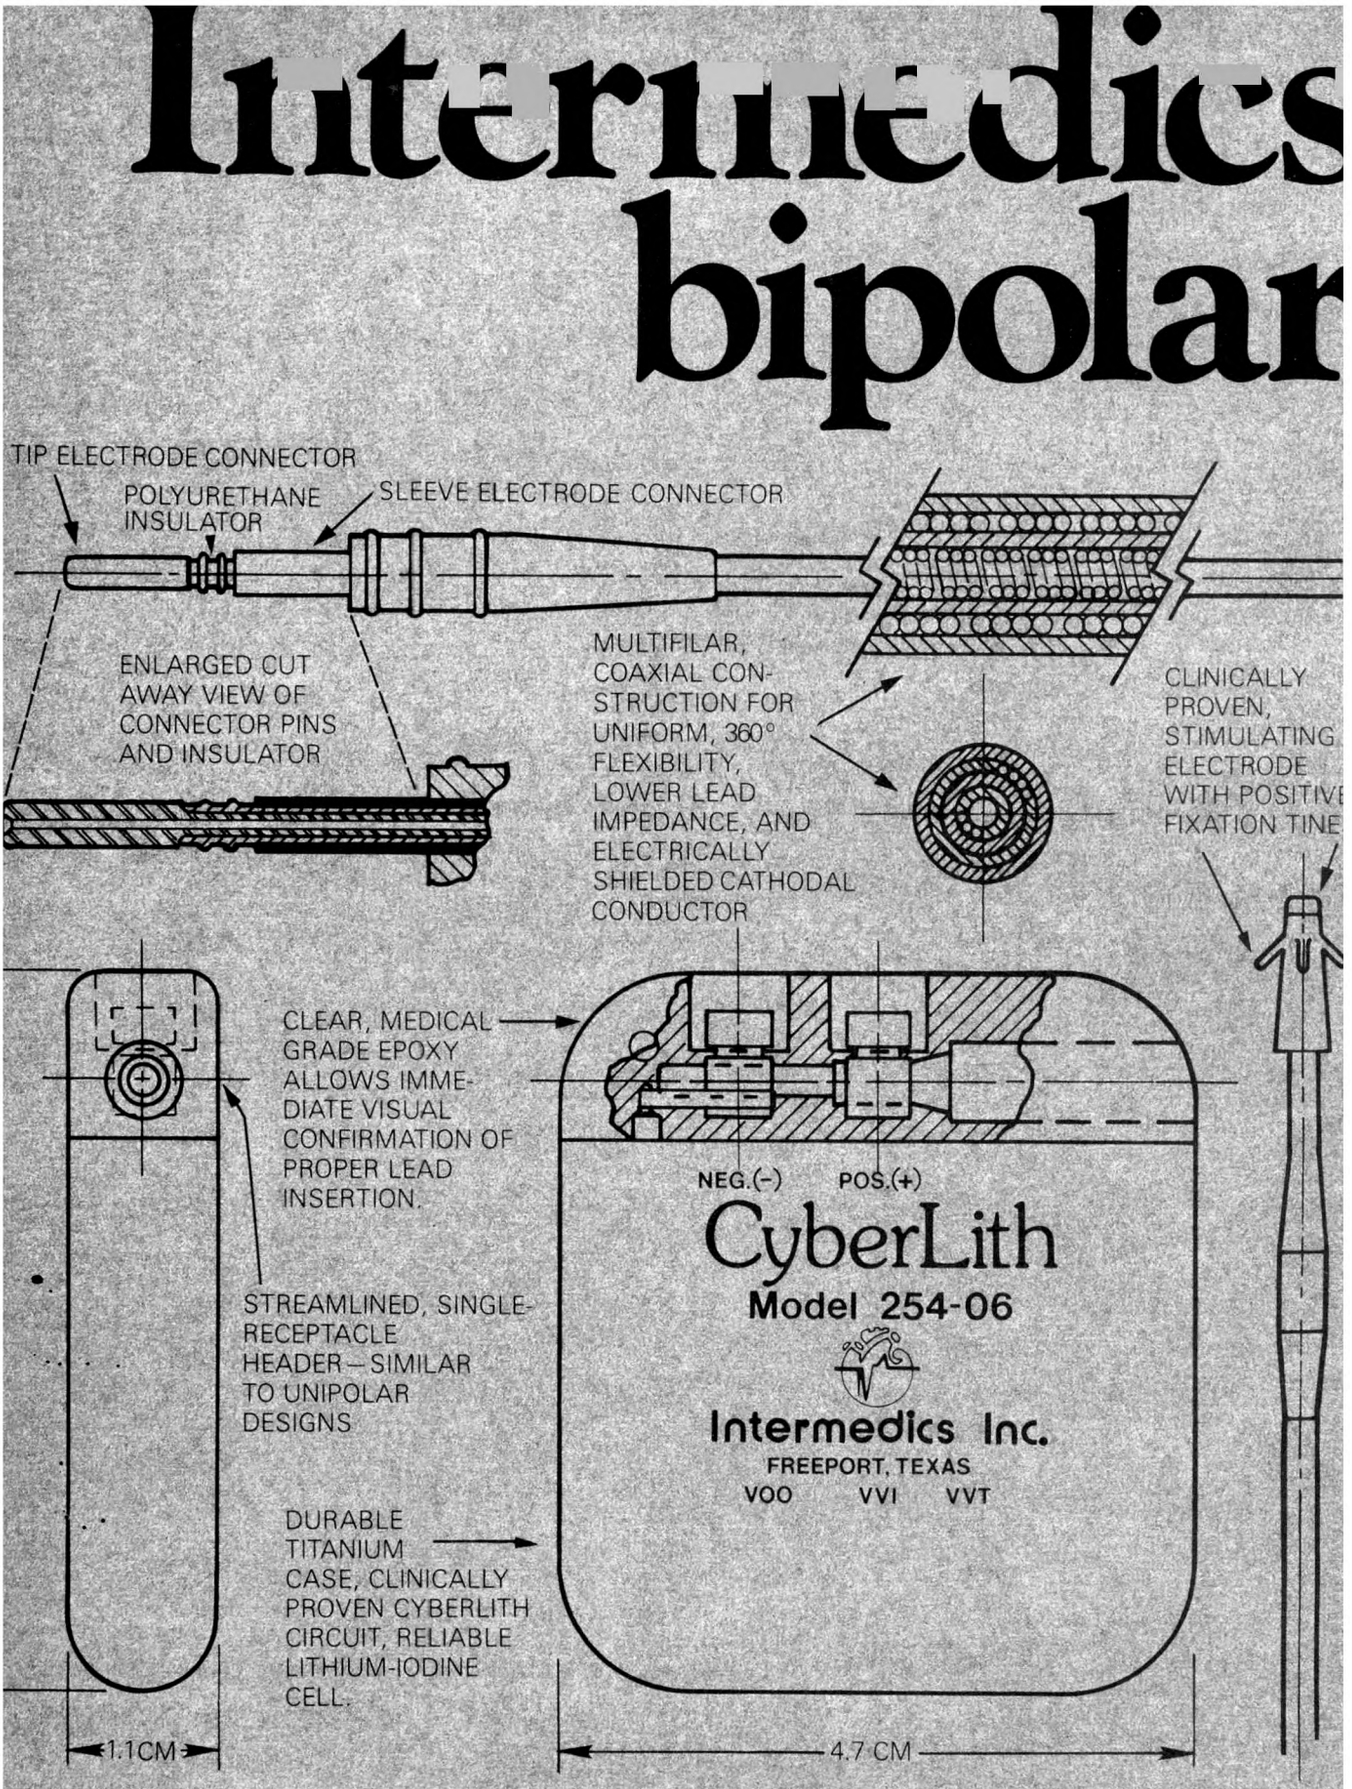
RSE REACTIONS: Nausea, vomiting, diarrhea, and abdominal discomfort may occur with the use of potassium salts.

GE AND ADMINISTRATION: Adults: 1 tablet completely dissolved 1 to 2 times daily, depending upon the requirements of the patient; 1 tablet q potassium chloride) in 6 to 8 ounces of cold or ice water. The normal adult daily requirement is approximately 50 mEq of elemental potassium. **It is suggested that K-LYTE/CL 50 mEq be taken with meals and sipped slowly over a 5-10 minute period.**

SUPPLIED: K-LYTE/CL 50 mEq effervescent tablets (fruit punch and citrus flavors) cartons of 30 and 100. Also available, K-LYTE/CL effer- nt tablets (25 mEq fruit punch and citrus flavors) cartons of 30 and 250. Each tablet is individually foil wrapped.

Mead Johnson PHARMACEUTICAL DIVISION

Intermedics bipolar



Intermedics Pulse Generators

INDICATIONS AND CONTRAINDICATIONS

The indications for cardiac pacemaking are increasing as pacemakers become more sophisticated and as advanced methods for patient management become more widespread. Generally accepted indications for long-term cardiac pacing include but are not limited to:

(1) sick sinus syndrome; (2) chronic, symptomatic drug-resistant sinus arrhythmias, including sinus bradycardia, sinus arrest, and sinoatrial (S-A) block as seen in sick sinus syndrome; (3) chronic, symptomatic second-degree or third-degree A-V block; (4) recurrent Adams-Stokes syndrome; (5) bradycardia-tachycardia syndrome; (6) symptomatic bilateral bundle branch block; and (7) hypersensitive carotid sinus syndrome (carotid sinus syncope). In addition, certain patients presenting with intractable, recurrent, congestive heart failure; cerebral or renal insufficiency; or recurrent, drug-resistant tachyarrhythmias who have been shown to benefit from temporary cardiac pacing are considered candidates for permanent cardiac pacemaking.

The indications for permanent pacing in the presence of acute myocardial infarction have not yet

streamlines pacing.

NEW, easy-to-use bipolar technology plus PROVEN CyberLith® circuitry.

The New Standard For Bipolar Pacing.

Intermedics in-line technology is an entirely new concept in bipolar pacing. It permits a bipolar pacing system to be as thin, small, and lightweight as most unipolar systems; it offers remarkable convenience and simplicity of use; and it provides unparalleled immunity to non-cardiac signals.

Exceptional Noise And Artifact Immunity.

Intermedics in-line bipolar concept has added an important dimension to the ability to reject undesired signals. The lead conductors are coaxial providing shielding all the way from the pulse generator to the ring electrode. The result is a clean, crisp intracardiac signal to the sensing circuitry of the pacemaker, free from unwanted noise or other artifacts. No other bipolar pacemaker available offers this advantage.

Simple, Convenient Implantation.

The CyberLith I model 254-06, the newest member of the CyberLith family of pacemakers, is the first multiprogrammable pacemaker to use the new in-line technology. A simple, in-line connector eliminates the bulky, bifurcated connectors in the pacemaker and the lead. The smaller, physiologically compatible pacemaker fits easily in the pocket.

Intermedics—On The Leading Edge Of Pacemaker Technology.

Innovation is not the only reason for selecting an Intermedics product. The CyberLith family of pacemakers is unsurpassed in clinical experience, proven performance and reliability.

To find out more about the new convenience of bipolar pacing, contact your Intermedics representative or call us toll-free at 800/231-2330.

been rigorously defined. Factors to be considered include the location of the myocardial infarct, the presence or absence of symptoms, ventricular rate, mechanism of the arrhythmias, and response to therapy. In general, symotomatic drug-resistant bradyarrhythmias which impair cardiac output are considered indications for pacing in patients with acute myocardial infarction, regardless of infarct

There are no known contraindications to the use of pacemakers as a medical method for control of heart rate. However, body rejection phenomena such as local tissue reaction or skin necrosis, muscle and nerve stimulation, embolism, and cardiac tamponade have been reported.

CAUTION: Federal (U.S.A.) law restricts this de-

CARDIOQUIN®
TABLETS
(quinidine polygalacturonate)

- ☐ Greater GI tolerance than with quinidine sulfate
- ☐ Full quinidine cardiodynamics
- ☐ Convenient b.i.d. or t.i.d. dosage for most patients

CARDIOQUIN Tablets (quinidine polygalacturonate) are indicated in the treatment of a broad range of cardiac arrhythmias (see Brief Summary). After conversion to normal sinus rhythm —whether with CARDIOQUIN Tablets or electroconversion — only low b.i.d. or t.i.d. dosage of this unique polygalacturonate salt of quinidine is required for maintenance in most cases. The polygalacturonic acid serves as a buffering moiety. It protects the mucosa of the stomach and permits dependable absorption of the quinidine.*

*Aviado, D. M., Krantz and Carr's Pharmacologic Principles of Medical Practice, ed. 8, Baltimore, Williams and Wilkins Co., 1972, p. 456.

BRIEF SUMMARY—INDICATIONS: CARDIOQUIN Tablets (quinidine polygalacturonate) are indicated in the treatment of: premature atrial and ventricular contractions; paroxysmal atrial tachycardia; paroxysmal AV junctional rhythm; atrial flutter; paroxysmal atrial fibrillation; established atrial fibrillation when therapy is appropriate; paroxysmal ventricular tachycardia when not associated with complete heart-block; maintenance therapy after electrical conversion of atrial fibrillation and/or flutter. CONTRAINDICATIONS: Aberrant impulses and abnormal rhythms due to escape mechanisms should not be treated with quinidine. WARNING: In the treatment of atrial flutter reversion to sinus rhythm may be preceded by a progressive reduction in the degree of AV block to a 1:1 ratio and resulting extremely rapid ventricular rate. COMPOSITION: Each CARDIOQUIN Tablet (quinidine polygalacturonate 275 mg.) is equivalent in quinidine content to 3 grains quinidine sulfate. DOSAGE AND ADMINISTRATION: Dosage must be adjusted to individual needs, both for conversion and maintenance. An initial dose of 1 to 3 tablets may be used to terminate arrhythmias, and may be repeated in 3-4 hours. If normal sinus rhythm is not restored after 3 or 4 equal doses, the dose may be increased by ½ to 1 tablet (137.5 to 275 mg.) and administered three to four times before any further dosage increase. For maintenance, one tablet may be used two to three times a day; generally one tablet morning and night will be adequate. SUPPLIED: Uncoated, scored tablets in bottles of 100.

ANSWERS ABOUT ALDOMET® (METHYLDOPA|MSD)

Will an antihypertensive generally allow a normal cardiovascular response to exercise?

Cardiac output and blood pressure normally increase with increasing physical activity. ALDOMET does not significantly impair normal fluctuations of blood pressure during exercise.[1,2]

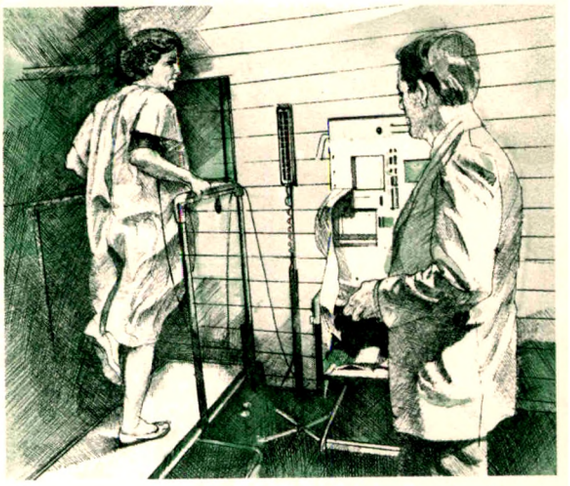
In a recent study of hypertensive patients whose cardiovascular response to exercise was evaluated before and during methyldopa therapy, "...methyldopa significantly reduced the rise in systolic pressure during the build-up ($P<0.01$) and subjective maximal stages ($P<0.05$) as well as at all phases of recovery ($P<0.01$)." Moreover, "The total duration of exercise (an index of work capacity) was unchanged with...methyldopa."[3]

Such findings can be of importance to active hypertensive patients such as the athletic individual or the person whose work requires substantial physical effort. For these and many other hypertensive patients, ALDOMET represents a logical therapeutic choice.

With ALDOMET, exercise hypotension rarely occurs. Sedation, usually transient, may occur during the initial period of therapy or whenever the dose is increased. Headache, asthenia, or weakness may be noted as early and transient symptoms.

ALDOMET® offers many (METHYLDOPA|MSD) other important features:

- Highly effective in all degrees of hypertension.
- Existing cardiac output is usually maintained.
- Renal blood flow is usually maintained.
- Has documented long-term efficacy.
- Significant adverse effects have been infrequent and the agent is usually well tolerated.



ALDOMET is contraindicated in active hepatic disease, hypersensitivity to the drug, and if previous methyldopa therapy has been associated with liver disorders. It is important to recognize that a positive Coombs test, hemolytic anemia, and liver disorders may occur with methyldopa therapy. The rare occurrences of hemolytic anemia or liver disorders could lead to potentially fatal complications unless properly recognized and managed.

MERCK SHARP & DOHME
LIBRARY

For hypertension—

ALDOMET®
(METHYLDOPA | MSD)

The most prescribed nondiuretic antihypertensive in the U.S. today

Contraindications: Active hepatic disease, such as acute hepatitis and active cirrhosis; if previous methyldopa therapy has been associated with liver disorders (see Warnings); hypersensitivity.

Warnings: It is important to recognize that a positive Coombs test, hemolytic anemia, and liver disorders may occur with methyldopa therapy. The rare occurrences of hemolytic anemia or liver disorders could lead to potentially fatal complications unless properly recognized and managed. Read this section carefully to understand these reactions.

With prolonged methyldopa therapy, 10% to 20% of patients develop a positive direct Coombs test, usually between 6 and 12 months of therapy. Lowest incidence is at daily dosage of 1 g or less. This on rare occasions may be associated with hemolytic anemia, which could lead to potentially fatal complications. One cannot predict which patients with a positive direct Coombs test may develop hemolytic anemia. Prior existence or development of a positive direct Coombs test is not in itself a contraindication to use of methyldopa. If a positive Coombs test develops during methyldopa therapy, determine whether hemolytic anemia exists and whether the positive Coombs test may be a problem. For example, in addition to a positive direct Coombs test there is less often a positive indirect Coombs test which may interfere with cross matching of blood.

At the start of methyldopa therapy, it is desirable to do a blood count (hematocrit, hemoglobin, or red cell count) for a baseline or to establish whether there is anemia. Periodic blood counts should be done during therapy to detect hemolytic anemia. It may be useful to do a direct Coombs test before therapy and at 6 and 12 months after the start of therapy. If Coombs-positive hemolytic anemia occurs, the cause may be methyldopa and the drug should be discontinued. Usually the anemia remits promptly. If not, corticosteroids may be given and other causes of anemia should be considered. If the hemolytic anemia is related to methyldopa, the drug should not be reinstituted. When methyldopa causes Coombs positivity alone or with hemolytic anemia, the red cell is usually coated with gamma globulin of the IgG (gamma G) class only. The positive Coombs test may not revert to normal until weeks to months after methyldopa is stopped.

Should the need for transfusion arise in a patient receiving methyldopa, both a direct and an indirect Coombs test should be performed on his blood. In the absence of hemolytic anemia, usually only the direct Coombs test will be positive. A positive direct Coombs test alone will not interfere with typing or cross matching. If the indirect Coombs test is also positive, problems may arise in the major cross match and the assistance of a hematologist or transfusion expert will be needed.

Fever has occurred within first 3 weeks of therapy, occasionally with eosinophilia or abnormalities in liver function tests, such as serum alkaline phosphatase, serum transaminases (SGOT, SGPT), bilirubin, cephalin cholesterol flocculation, prothrombin time, and bromsulphalein retention. Jaundice, with or without fever, may occur, with onset usually in the first 2 to 3 months of therapy. In some patients the findings are consistent with those of cholestasis. Rarely fatal hepatic necrosis has been reported. These hepatic changes may represent hypersensitivity reactions; periodic determination of hepatic function should be done particularly during the first 6 to 12 weeks of therapy or whenever an unexplained fever occurs. If fever and abnormalities in liver function tests or jaundice appear, stop therapy with methyldopa. If caused by methyldopa, the temperature and abnormalities in liver function characteristically have reverted to normal when the drug was discontinued. Methyldopa should not be reinstituted in such patients.

Rarely, a reversible reduction of the white blood cell count with primary effect on granulocytes has been seen. Reversible thrombocytopenia has occurred rarely. When used with other antihypertensive drugs, potentiation of antihypertensive effect may occur. Patients should be followed carefully to detect side reactions or unusual manifestations of drug idiosyncrasy.

Pregnancy and Nursing: Use of any drug in women who are or may become pregnant or intend to nurse requires that anticipated benefits be weighed against possible risks; possibility of fetal injury or injury to a nursing infant cannot be excluded. Methyldopa crosses the placental barrier, appears in cord blood, and appears in breast milk.

Precautions: Should be used with caution in patients with history of previous liver disease or dysfunction (see Warnings). May interfere with measurement of: urinary uric acid by the phosphotungstate method, serum creatinine by the alkaline picrate method, and SGOT by colorimetric methods. Since methyldopa causes fluorescence in urine samples at the same wavelengths as catecholamines, falsely high levels of urinary catecholamines may be reported. This will interfere with the diagnosis of pheochromocytoma. It is important to recognize this phenomenon before a patient with a possible pheochromocytoma is subjected to surgery. Methyldopa is not recommended for patients with pheochromocytoma. Urine exposed to air after voiding may darken because of breakdown of methyldopa or its metabolites.

Stop drug if involuntary choreoathetotic movements occur in patients with severe bilateral cerebrovascular disease. Patients may require reduced doses of anesthetics; hypotension occurring during anesthesia usually can be controlled with vasopressors. Hypertension has recurred after dialysis in patients on methyldopa because the drug is removed by this procedure.

Adverse Reactions: *Central nervous system:* Sedation, headache, asthenia or weakness, usually early and transient; dizziness, lightheadedness, symptoms of cerebrovascular insufficiency, paresthesias, parkinsonism, Bell's palsy, decreased mental acuity, involuntary choreoathetotic movements; psychic disturbances, including nightmares and reversible mild psychoses or depression.

Cardiovascular: Bradycardia, aggravation of angina pectoris. Orthostatic hypotension (decrease daily dosage). Edema (and weight gain) usually relieved by use of a diuretic. (Discontinue methyldopa if edema progresses or signs of heart failure appear.)

Gastrointestinal: Nausea, vomiting, distention, constipation, flatus, diarrhea, mild dryness of mouth, sore or "black" tongue, pancreatitis, sialadenitis.

Hepatic: Abnormal liver function tests, jaundice, liver disorders.

Hematologic: Positive Coombs test, hemolytic anemia. Leukopenia, granulocytopenia, thrombocytopenia. Positive tests for antinuclear antibody, LE cells, and rheumatoid factor.

Allergic: Drug-related fever, lupus-like syndrome, myocarditis.

Other: Nasal stuffiness, rise in BUN, breast enlargement, gynecomastia, lactation, impotence, decreased libido, dermatologic reactions including eczema and lichenoid eruptions, mild arthralgia, myalgia.

Note: Initial adult dosage should be limited to 500 mg daily when given with antihypertensives other than thiazides. Tolerance may occur, usually between second and third months of therapy; increased dosage or adding a diuretic frequently restores effective control. Patients with impaired renal function may respond to smaller doses. Syncope in older patients may be related to increased sensitivity and advanced arteriosclerotic vascular disease; this may be avoided by lower doses.

How Supplied: Tablets, containing 125 mg methyldopa each, in bottles of 100; Tablets, containing 250 mg methyldopa each, in single-unit packages of 100 and bottles of 100 and 1000; Tablets, containing 500 mg methyldopa each, in single-unit packages of 100 and bottles of 100 and 500.

INTROPIN® RESPONDS
(dopamine HCl)

MATCH CHANGING CONDITIONS IN SHOCK BY FINE-TUNING DOSAGE

Intropin—at any point in time in shock

No other drug works like Intropin® (dopamine HCl) in "routing" blood where it is needed, and when it is needed, to maintain vital organ perfusion. Careful dosage titration provides the particular hemodynamic/renal effects you desire for any given patient, at any point in time, over a wide range of shock symptoms.

Unique dosage flexibility... unique patient response

Slightly hypotensive patients with low but adequate cardiac output, falling urine output and reduced vital organ perfusion usually experience increased urine flow, modest increases in cardiac output and reduced peripheral resistance with low Intropin doses (2-5 mcg/kg/min).

Moderate hypotension, reduced cardiac output and venous return plus further reductions in urine output are likely to respond to intermediate (5-20 mcg/kg/min) Intropin doses by showing further increases in cardiac output, blood pressure, vital organ perfusion and urine flow.

When severely hypotensive patients with greatly reduced systemic vascular resistance, cardiac and urine output and poor perfusion are given Intropin doses of greater than 20 mcg/kg/min, the blood pressure increases (due to increases in both cardiac output and SVR) while the mild dopaminergic action on the kidney may be somewhat offset by the alpha effect.

Intropin—maintains vital organ perfusion in patients at high risk of shock

Beneficial Intropin effects result from:

- direct increase in blood flow to vital organs, due to dilation of blood vessels in the renal, coronary and mesenteric areas as well as constriction of vasculature of the skin and muscle.
- predictable increase in urine output.
- direct increase of cardiac output, primarily due to increased stroke volume.
- predictable maintenance or increase in blood pressure.

By comparison, other catacholamines (dobutamine, isoproterenol, norepinephrine) while usually favorably affecting cardiac output, may have unpredictable (or even adverse) effects on blood pressure, coronary perfusion or circulation to other vital organs. Increasing the dosage intensifies both the favorable and unfavorable actions of these drugs.

Intropin—recommended for any patient in shock due to:

- myocardial infarction
- trauma
- endotoxic septicemia
- open heart surgery
- renal failure
- congestive heart failure

Intropin dosage forms and concentrations designed for fast, convenient patient care

Please see following page for prescribing information. For further information, please contact Medical Services Department of American Critical Care, Division of American Hospital Supply Corporation, 1600 Waukegan Road, McGaw Park, Illinois 60085 Phone 312-473-3000.

INTROPIN®
(dopamine HCl)

©1980 American Critical Care
Division of American Hospital Supply Corporation

American Critical Care
(formerly Arnar-Stone Laboratories)

INTROPIN (dopamine HCl)

5 ml AMPUL and SINGLE-DOSE VIAL
5 ml ADDITIVE SYRINGE (Rap-Add®)
(200 mg and 400 mg concentrations)

BRIEF SUMMARY OF PRESCRIBING INFORMATION

DESCRIPTION: INTROPIN (dopamine HCl) is 3, 4-dihydroxyphenethylamine hydrochloride, a naturally occurring biochemical-cathecholamine precursor of norepinephrine. Intropin is a clear, aqueous additive solution for intravenous infusion after dilution.

INDICATIONS: For the correction of hemodynamic imbalances present in the shock syndrome due to myocardial infarctions, trauma, endotoxic septicemia, open heart surgery, renal failure, and chronic cardiac decompensation as in congestive failure.

Poor Perfusion of Vital Organs – Urine flow appears to be one of the better diagnostic signs by which adequacy of vital organ perfusion can be monitored. The physician should also observe the patient for signs of reversal of confusion or comatose condition. Loss of pallor, increase in toe temperature and/or adequacy of nail bed capillary filling may also be used as indices of adequate dosage. Note that at doses above those optimal for the individual patient, urine flow may decrease, necessitating reduction of dosage. Concurrent administration of INTROPIN and diuretic agents may produce a potentiating effect.

Low Cardiac Output – Increased cardiac output is related to the direct inotropic effect of INTROPIN on the myocardium. Increased cardiac output at low or moderate doses has been associated with either static or decreased systemic vascular resistance (SVR) and appears to be related to a favorable prognosis. Increase in cardiac output produced by INTROPIN is not associated with substantial decreases in SVR as may occur with isoproterenol.

Hypotension – Hypotension due to inadequate cardiac output can be managed by administration of low to moderate doses of INTROPIN, which have little effect on SVR. At high therapeutic doses, the drug's alpha adrenergic activity becomes more prominent and thus may correct hypotension due to diminished SVR. Administration should be considered as soon as a definite trend toward decreased systolic and diastolic pressure becomes evident.

CONTRAINDICATIONS: INTROPIN should not be used in patients with pheochromocytoma.

WARNINGS: INTROPIN should not be administered in the presence of uncorrected tachyarrhythmias or ventricular fibrillation. INTROPIN should not be added to any alkaline diluent solution since the drug is inactivated in alkaline solutions. Patients who have been treated with monamine oxidase (MAO) inhibitors prior to the administration of INTROPIN will require substantially reduced dosage (1/10 the usual starting dose).

Usage in Pregnancy – INTROPIN may be used in pregnant patients when, in the judgment of the physician, the expected benefits outweigh the potential risk to the fetus.

Usage in Children – The safety and efficacy of INTROPIN for pediatric use has not been established.

PRECAUTIONS: Avoid Hypovolemia – Prior to treatment with INTROPIN, hypovolemia should be fully corrected, if possible, with either whole blood or plasma as indicated.

Decreased Pulse Pressure – If a disproportionate rise in the diastolic pressure (i.e. a marked decrease in the pulse pressure) is observed in patients receiving INTROPIN, the infusion rate should be decreased and the patient observed carefully for further evidence of predominant vasoconstrictor activity, unless such an effect is desired.

Extravasation – INTROPIN should be infused into a large vein whenever possible to prevent the possibility of extravasation into tissue adjacent to the infusion site which may cause necrosis and sloughing of surrounding tissue. Large veins of the antecubital fossa are preferred to veins in the dorsum of the hand or ankle.

IMPORTANT – Antidote for Peripheral Ischemia: To prevent sloughing and necrosis in ischemic areas, the area should be infiltrated as soon as possible with 10 to 15 ml of saline solution containing from 5 to 10 mg of Regitine* (brand of phentolamine), an adrenergic blocking agent. A syringe with a fine hypodermic needle should be used, and the solution liberally infiltrated throughout the ischemic area. Sympathetic blockade with phentolamine causes immediate and conspicuous local hyperemic changes if the area is infiltrated within 12 hours. Therefore, *phentolamine should be given as soon as possible* after the extravasation is noted.

Avoid Cyclopropane or Halogenated Hydrocarbon Anesthetics – Because of the theoretical arrhythmogenic potential of these agents and the known increase in cardiac autonomic irritability which may sensitize the myocardium, INTROPIN should be used with EXTREME CAUTION in patients inhaling such anesthetics.

Careful Monitoring Required – As in the case of any adrenergic agent, infusion of INTROPIN should be accompanied by close monitoring of urine flow, cardiac output and blood pressure.

ADVERSE REACTIONS: The most frequent include ectopic beats, nausea, vomiting, tachycardia, anginal pain, palpitation, dyspnea, headache, hypotension, and vasoconstriction. Others reported infrequently are aberrant conduction, bradycardia, piloerection, widened QRS complex, azotemia, and elevated blood pressure.

WARNING: This is a potent drug – must be diluted before administration to patient.

OVERDOSAGE: In case of accidental overdosage, as evidenced by excessive blood pressure elevation, reduce rate of administration or temporarily discontinue INTROPIN until patient's condition stabilizes. Since the drug's duration of action is quite short, no additional remedial measures are usually necessary. If these measures fail to stabilize the patient's condition, use of the short-acting alpha adrenergic blocking agent, phentolamine, should be considered.

HOW SUPPLIED:
– 200 mg (5 ml containing 40 mg dopamine HCl per ml). NDC 0094-0040-05 – Ampul. NDC 0094-0040-06 – Single-dose vial (color coded white). NDC 0094-0040-07 – RAP-ADD® Additive Syringe (color coded white).
– 400 mg (5 ml containing 80 mg dopamine HCl per ml). NDC 0094-0046-06 – Single-dose vial (color coded green). NDC 0094-0046-07 – RAP-ADD® Additive Syringe (color coded green).

CAUTION: Federal law prohibits dispensing without a prescription. Full directions for use should be read before administering or prescribing.

Electrophysiologic Basis for Diagnosis and Management of Cardiac Arrhythmias
June 4-6, 1981
Performing Arts Center, Milwaukee, Wisconsin

During this two and one-half day course, an update of current diagnostic and therapeutic approaches to cardiac arrhythmias will be presented by internationally recognized authorities in the field. Emphasis will be placed on the use of both surface and intracardiac electrocardiography for the correct diagnosis of arrhythmias. The role of cardiac stimulation in the initiation and control of all types of cardiac arrhythmias will be presented. The program will consist of five sessions with panel discussions each devoted to an important area of rhythm disturbance. A full day will be spent on presentations dealing with diagnostic and therapeutic aspects of ventricular arrhythmias in various clinical settings.

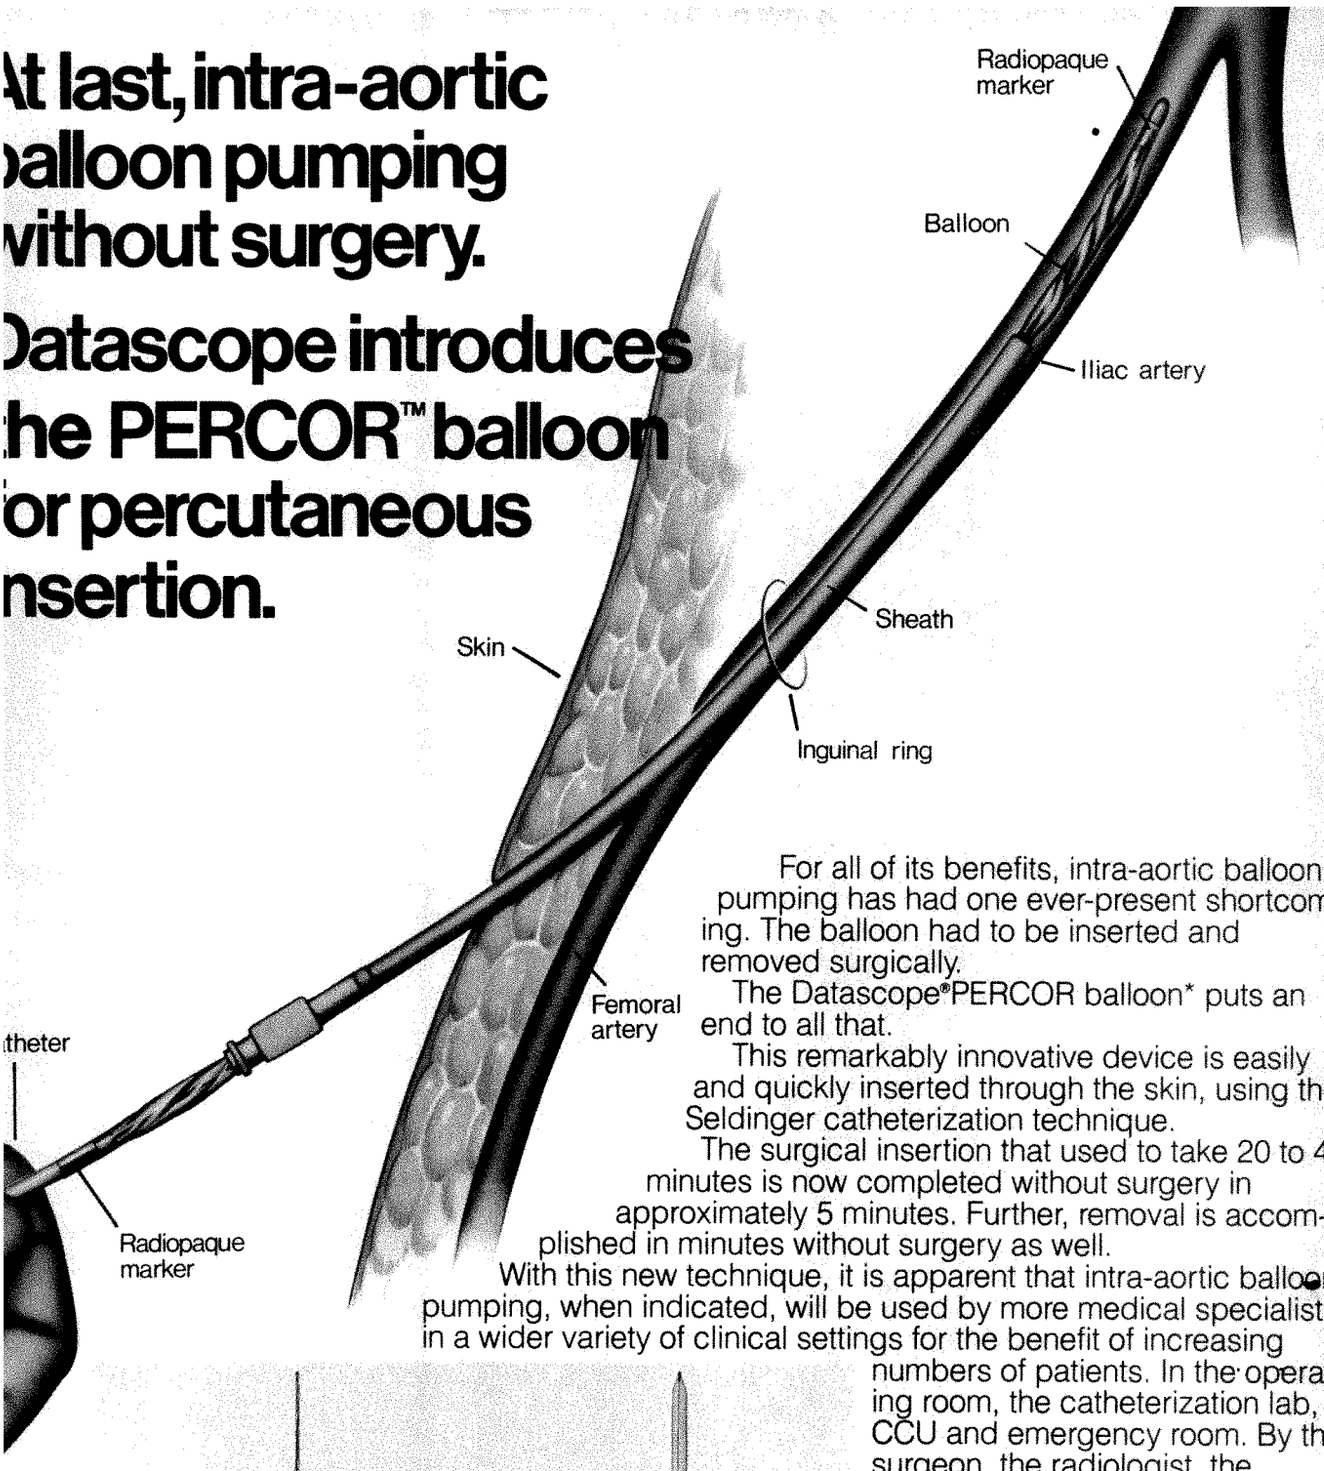
At last, intra-aortic balloon pumping without surgery.

Datascope introduces the PERCOR™ balloon for percutaneous insertion.



For all of its benefits, intra-aortic balloon pumping has had one ever-present shortcoming. The balloon had to be inserted and removed surgically.

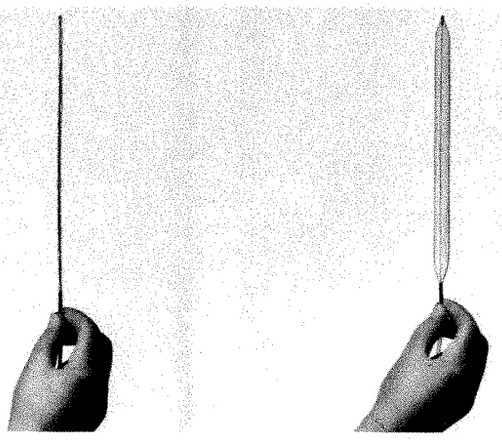
The Datascope®PERCOR balloon* puts an end to all that.

This remarkably innovative device is easily and quickly inserted through the skin, using the Seldinger catheterization technique.

The surgical insertion that used to take 20 to 45 minutes is now completed without surgery in approximately 5 minutes. Further, removal is accomplished in minutes without surgery as well.

With this new technique, it is apparent that intra-aortic balloon pumping, when indicated, will be used by more medical specialists in a wider variety of clinical settings for the benefit of increasing numbers of patients. In the operating room, the catheterization lab, CCU and emergency room. By the surgeon, the radiologist, the cardiologist.

We would be pleased to send you more information about our revolutionary device and to schedule a filmed demonstration of its use. Call Robert Rewolinski, Manager, Cardiac Assist Products, at 201-265-8800 or write him at Datascope Corp., Dept. #5-S, 580 Winters Avenue, Paramus, NJ 07652.



PERCOR™ balloon ready for insertion.

PERCOR™ inflated.

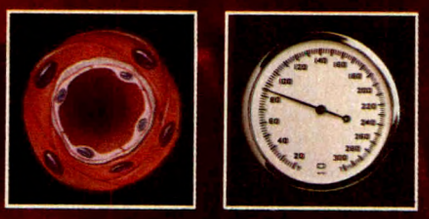
MINIPRESS® Effecti
(prazosin HCl)
by Reduc
Artist's representation of the lumen of an arteriole,
dilation of which results in reduced peripheral resistance
and blood pressure.

Controls Hypertension
Peripheral Resistance



- MINIPRESS Reduces Mean Arterial Pressure
- MINIPRESS Reduces Total Peripheral Resistance
- MINIPRESS Does Not Reduce Cardiac Index

...and Maintains These Effects Over the Long Term

Relative hemodynamic changes at rest and during exercise after one year of prazosin therapy in 10 hypertensive patients. Adapted from Lund-Johansen[1]

Rest Exercise

MINIPRESS®
(prazosin HCl)

Capsules 1 mg, 2 mg, 5 mg

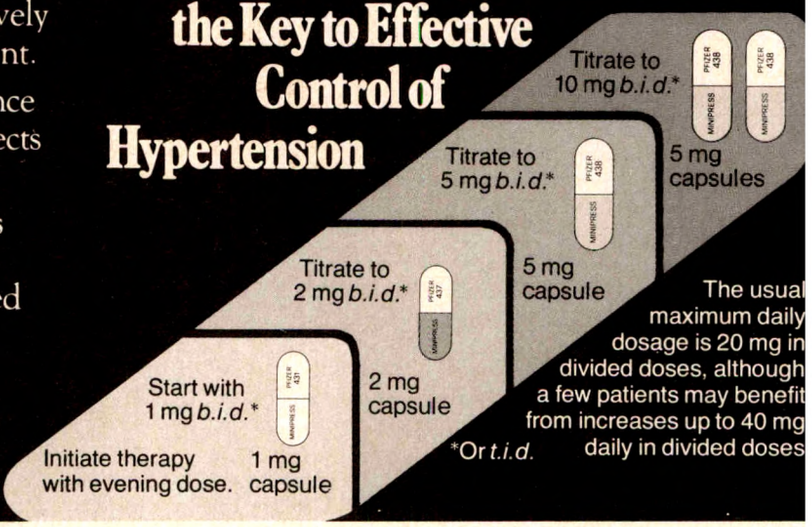
Please see Brief Summary on last page.

© 1980, Pfizer Inc.

MINIPRESS®
(prazosin HCl) Capsules 1 mg, 2 mg, 5 mg

- **Effectively lowers elevated blood pressure by reducing peripheral resistance.**
- **Maintains cardiac output** which allows patients to maintain an active life style.
- **Maintains renal blood flow and glomerular filtration rate** so it can be used effectively even in patients with renal impairment.
- **Not a CNS agent** so patients experience few of the troublesome CNS side effects that impair their quality of life.
- **Cardiovascular response to exercise is preserved** so patients are less likely to experience the fatigue often associated with beta-blocker therapy.
- **A small percentage of patients** have experienced orthostatic hypotension and syncope.

B.I.D. Dosage Titration... the Key to Effective Control of Hypertension



BRIEF SUMMARY
MINIPRESS® (prazosin hydrochloride) CAPSULES *For Oral Use*

INDICATIONS: MINIPRESS® (prazosin hydrochloride) is indicated in the treatment of hypertension. As an antihypertensive drug, it is mild to moderate in activity. It can be used as the initial agent or it may be employed in a general treatment program in conjunction with a diuretic and/or other antihypertensive drugs as needed for proper patient response.

WARNINGS: MINIPRESS (prazosin hydrochloride) may cause syncope with sudden loss of consciousness. In most cases this is believed to be due to an excessive postural hypotensive effect, although occasionally the syncopal episode has been preceded by a bout of severe tachycardia with heart rates of 120-160 beats per minute. Syncopal episodes have usually occurred within 30 to 90 minutes of the initial dose of the drug; occasionally they have been reported in association with rapid dosage increases or the introduction of another antihypertensive drug into the regimen of a patient taking high doses of MINIPRESS (prazosin hydrochloride). The incidence of syncopal episodes is approximately 1% in patients given an initial dose of 2 mg or greater. Clinical trials conducted during the investigational phase of this drug suggest that syncopal episodes can be minimized by limiting the initial dose of the drug to 1 mg, by subsequently increasing the dosage slowly, and by introducing any additional antihypertensive drugs into the patient's regimen with caution (see DOSAGE AND ADMINISTRATION). Hypotension may develop in patients given MINIPRESS who are also receiving a beta-blocker such as propranolol.

If syncope occurs, the patient should be placed in the recumbent position and treated supportively as necessary. This adverse effect is self-limiting and in most cases does not recur after the initial period of therapy or during subsequent dose titration.

Patients should always be started on the 1 mg capsules of MINIPRESS (prazosin hydrochloride). The 2 and 5 mg capsules are not indicated for initial therapy.

More common than loss of consciousness are the symptoms often associated with lowering of the blood pressure, namely, dizziness and lightheadedness. The patient should be cautioned about these possible adverse effects and advised what measures to take should they develop. The patient should also be cautioned to avoid situations where injury could result should syncope occur during the initiation of MINIPRESS (prazosin hydrochloride) therapy.

Usage in Pregnancy: Although no teratogenic effects were seen in animal testing, the safety of MINIPRESS (prazosin hydrochloride) in pregnancy has not been established. MINIPRESS (prazosin hydrochloride) is not recommended in pregnant women unless the potential benefit outweighs potential risk to mother and fetus.

Usage in Children: No clinical experience is available with the use of MINIPRESS (prazosin hydrochloride) in children.

ADVERSE REACTIONS: The most common reactions associated with MINIPRESS (prazosin hydrochloride) therapy are: dizziness 10.3%, headache 7.8%, drowsiness 7.6%, lack of energy 6.9%, weakness 6.5%, palpitations 5.3%, and nausea 4.9%. In most instances side effects have disappeared with continued therapy or have been tolerated with no decrease in dose of drug.

The following reactions have been associated with MINIPRESS (prazosin hydrochloride), some of them rarely. (In some instances exact causal relationships have not been established).

Gastrointestinal: vomiting, diarrhea, constipation, abdominal discomfort and/or pain.

Cardiovascular: edema, dyspnea, syncope, tachycardia.

Central Nervous System: nervousness, vertigo, depression, paresthesia.

Dermatologic: rash, pruritus.

Genitourinary: urinary frequency, incontinence, impotence.

EENT: blurred vision, reddened sclera, epistaxis, tinnitus, dry mouth, nasal congestion.

Other: diaphoresis.

Single reports of pigmentary mottling and serous retinopathy, and a few reports of cataract development or disappearance have been reported. In these instances, the exact causal relationship has not been established because the baseline observations were frequently inadequate.

In more specific slit-lamp and funduscopic studies, which included adequate baseline examinations, no drug-related abnormal ophthalmological findings have been reported.

DOSAGE AND ADMINISTRATION: The dose of MINIPRESS (prazosin hydrochloride) should be adjusted according to the patient's individual blood pressure response. The following is a guide to its administration:

Initial Dose: 1 mg two or three times a day. (See Warnings).

Maintenance Dose: Dosage may be slowly increased to a total daily dose of 20 mg given in divided doses. The therapeutic dosages most commonly employed have ranged from 6 mg to 15 mg daily given in divided doses. Doses higher than 20 mg usually do not increase efficacy, however a few patients may benefit from further increases up to a daily dose of 40 mg given in divided doses. After initial titration some patients can be maintained adequately on a twice daily dosage regimen.

Use With Other Drugs: When adding a diuretic or other antihypertensive agent, the dose of MINIPRESS (prazosin hydrochloride) should be reduced to 1 mg or 2 mg three times a day and retitration then carried out.

HOW SUPPLIED: MINIPRESS (prazosin hydrochloride) is available in 1 mg (white #431), 2 mg (pink and white #437) capsules in bottles of 250, 1000, and unit dose institutional packages of 100 (10 x 10's); and 5 mg (blue and white #438) capsules in bottles of 250, 500 and unit dose institutional packages of 100 (10 x 10's).

More detailed information available on request.

Abstracts of Papers to Be Presented at the 30th Annual Scientific Session of the American College of Cardiology San Francisco, California, March 15–19, 1981

This year, a record number of abstracts (original contributions), 2,300, were submitted for evaluation. Each was graded by seven recognized authorities in a special area of interest. Acceptance for presentation was based on the relative grade ranking in each of these 17 categories.

Meeting space restrictions limited the total number of original contributions that could be presented to 18 percent of the number submitted, or 442 abstracts. This, however, represents the largest number of abstracts accepted for presentation at any American College of Cardiology Annual Scientific Session. Many excellent contributions could not be included in the program because of the space limitations. We regret any disappointment this has undoubtedly caused many authors.

PHARMACOLOGY: VASODILATORS—NEW CONCEPTS
10:30–12:00

DIRECT EFFECTS OF PRAZOSIN ON THE CANINE SINUS NODE. Kerry M. Schwartz, M.D., Ferdinand Urthaler, M.D., and Thomas N. James, M.D., FACC. University of Alabama in Birmingham, Birmingham, Alabama.

Prazosin differs from most blockers of post-synaptic alpha adrenoceptors by rarely causing the expected reflex tachycardia. Selective perfusion (2 ml) of the sinus node artery (SNA) of 16 anesthetized dogs was utilized to assess the direct and indirect chronotropic effects of prazosin (PRZ). Concentrations of 1.0, 10, 50, and 100 µg/ml produced cumulative, dose-related reductions in mean sinus rate (SR) of 4.4 ± 2; 10.3 ± 6; 15 ± 9; and 27 ± 15 beats/min respectively ($p < .0001$). Intranodal PRZ (1.0-100 µg/ml) did not significantly alter the sinus node response to intranodal norepinephrine (NE) (.05 and .10 µg/ml) given via the SNA (n=6). SR acceleration (stimulus frequency response curve) after right stellate stimulation (n=6) was also not influenced by PRZ (control % change at 8 Hz was 45 ± 17 vs PRZ 48 ± 17, 40 ± 19, 52 ± 14, 53 ± 14 for 1, 10, 50, 100 µg/ml doses respectively; control % at 16 Hz was 50 ± 19 vs PRZ 52 ± 20, 52 ± 23, 57 ± 15, 55 ± 16; control % at 32 Hz was 52 ± 20 vs 57 ± 23, 61 ± 23 and 58 ± 18 respectively). Response to vagal stimulation (n=8) was also not affected by prior administration of PRZ in SNA (control % slowing at 8 Hz was 39 ± 12 vs PRZ 40 ± 14, 39 ± 13, 37 ± 14 and 35 ± 14; control at 16 Hz was 58 ± 9 vs PRZ 59 ± 11, 60 ± 11, 57 ± 16 and 47 ± 20, for 1, 10, 50, 100 µg/ml respectively). Conclusion: Prazosin exerts a direct negative chronotropic effect without exerting any significant influence on the neurohumoral autonomic control of the sinus node.

MECHANISM OF TRANSIENT PRAZOSIN HEMODYNAMIC "TACHYPHYLAXIS" IN HEART FAILURE: ACUTE, SUBACUTE AND LATE SERIAL EVALUATION OF ALPHA RECEPTOR RESPONSES WITH PHENYLEPHRINE BY CARDIAC CATHETERIZATION DURING PROLONGED ORAL PRAZOSIN THERAPY.
Dean T. Mason, MD, FACC; Najam A. Awan, MD, FACC; Kathleen E. Needham, BS; Mark Evenson, BS; Ezra A. Amsterdam, MD, FACC, University of California, Davis.

The mechanism of subacute hemodynamic "tachyphylaxis" (TX) to oral prazosin (PZ) during long-term ambulatory therapy of chronic congestive heart failure (CHF) is unknown. Accordingly, constant dose (20 ug/min) phenylephrine (PH) was serially infused during cardiac catheterization before and after oral prazosin on Day 1, Day 4, and Day 30 of continuous oral PZ (5 mgm q.i.d.) therapy in 9 patients with severe CHF. Measurements: MBP=mean blood pressure, mmHg; LVFP=left ventricular filling pressure, mmHg; CI=cardiac index, L/min/M^2. Control (C) vs drug: **=$p < 0.01$, + = $p < 0.001$. PZ vs PZ+PH: *=$p < 0.05$.

	DAY 1			DAY 4			DAY 30		
	MBP	LVFP	CI	MBP	LVFP	CI	MBP	LVFP	CI
C	79	22	2.2	79	22	2.4	81	22	2.1
PH	99+	31+	1.9**	89+	29**	2.3	91+	26**	2.2
PZ	71+	17+	2.6+	78	21	2.7	74+	17**	2.8+
PZ+PH	74*	19*	2.6	84*	25*	2.5	77	19*	2.8

Therefore PH raised BP and worsened cardiac function acutely, subacutely and on Day 30. Moreover while initial marked PZ beneficial effects were attenuated by Day 4, PZ vasodilator effects were fully restored by Day 30. Concomitantly initial post-PZ marked PH stimulation block was attenuated by Day 4 and recurred by Day 30. Thus the mechanism of PZ "tachyphylaxis" is altered PZ-alpha receptor interaction while alpha receptor integrity is maintained. Moreover this modified prazosin-alpha receptor response is transient and disappears during sustained oral PZ therapy of severe congestive heart failure.

ASSESSMENT OF PRAZOSIN ALPHA RECEPTOR BLOCKADE WITH PHENTOLAMINE: ACUTE, SUBACUTE AND LATE HEMODYNAMIC EVALUATION DURING SUSTAINED BENEFICIAL VASODILATOR THERAPY IN CONGESTIVE HEART FAILURE

Mark K. Evenson, BS; Najam A. Awan, MD, FACC; Kathleen E. Needham, BS; and Dean T. Mason, MD, FACC, University of California, Davis.

The mechanism of transient subacute hemodynamic blunting of prazosin (PZ) effects in therapy of chronic congestive heart failure (CHF) is uncertain. Therefore we evaluated the efficacy of PZ alpha receptor (AR) blockade by phentolamine (PT, 1.3 mg/min) acutely (Day 1), subacutely (Day 4) and chronically (Day 30) during continuous unaltered PZ (5 mg qid) therapy. Measurements: mean blood pressure (MBP), mmHg; left ventricular filling pressure (LVFP), mmHg; cardiac index (CI) L/min/M^2. Drug vs control (C): *=p<0.05, **=p<0.01, +=p<0.001, PZ+PT vs PZ: o=p<0.01.

	DAY 1			DAY 4			DAY 30		
	MBP	LVFP	CI	MBP	LVFP	CI	MBP	LVFP	CI
C	85	22	2.1	83	25	2.3	83	23	2.0
PT	72+	16*	2.4*	75+	23*	2.6+	79*	19*	2.5*
PZ	71+	17+	2.6+	82	23	2.5	74+	17**	2.8+
PZ+PT	70*^{o}	16+	2.5+	78*^{o}	21*^{o}	2.7*^{o}	78*	19**	2.6++

Accordingly, while the beneficial vasodilator effects of PT on cardiac function are blunted by salutary acute PZ responses on Day 1, during transient subacute PZ "tachyphylaxis" (Day 4) phentolamine responses are unaltered by PZ. Further with continuous 30 day oral PZ therapy of CHF, the spontaneous return of beneficial PZ effects causes restoration of post-PZ phentolamine block on Day 30. Thus the mechanism of transient PZ "tachyphylaxis" is temporarily modified PZ-AR relation while the alpha receptor itself remains responsive to vasodilation. Importantly, transient subacute blunting of PZ hemodynamic effects by modified PZ-AR interaction does not effect successful long term therapy of CHF with prazosin.

MAXIMAL IMPROVEMENT IN VENTRICULAR PERFORMANCE DURING REST AND EXERCISE IN CHRONIC SEVERE CARDIAC FAILURE BY COMBINED INOTROPIC AND VASODILATOR THERAPY COMPARED TO EITHER MODALITY ALONE.

Stephen P. Rosenfeld, M.D., FACC, M. Sheila Carney, R.N., Alan D. Waggoner, RDMS, Lawrence R. Poliner, M.D., FACC, Miguel A. Quinones, M.D., FACC, Craig M. Pratt, M.D., FACC, Richard R. Miller, M.D., FACC, Baylor College of Medicine, Houston, Texas.

Acutely, combined positive inotropic and vasodilator (Vas) therapy is superior to either individually in LV failure (F); however, the comparative effects chronically and at both rest (Rst) and exercise (Ex) are unknown. We compared digitalis (Dig) (serum level 1.3±.1 ng/ml) plus maximal Vas [prazosin (n=4) or hydralazine + nitrate (n=14)] and diuretic (DT) vs Dig+DT vs Vas+DT vs DT alone in 18 patients with extreme LVF [mean LV ejection fraction (EF) 16±7 (SD) % (all <30%), (nine ischemic)] by Rst and Ex radionuclide EF, treadmill (T) tolerance (sec), echophono and 48 hr ECG.

	Rst-EF	Ex-EF	T-Ex	EDD	PEP/LVET	PVC/hr
DT	16±2	20±3	362±40	6.5±.8	.59±.06	73±27
Dig	21±2†	21±3	336±61	6.6±.8	.50±.03**	88±32
Vas	19±3*	23±5	395±50	6.5±.8	.57±.04	82±24
Dig+Vas	23±3**	26±3†Ψ	409±70	6.5±.7	.53±.05	111±67

EDD=end-diastolic dimension (cm). *=p<.05 vs DT; †=p<.02 vs DT; **=p<.05 vs DT and Vas; Ψ=p<.05 vs Dig. Left atrial size was similar (p=ns) in each group. With Dig, Rst heart rate ↓ and Rst + Ex BP ↑ (p<.02) vs DT and Vas. Dig+Vas had lower (p<.02) PVC severity score vs Vas although PVC/hr were similar (p=ns). Thus, in extreme LVF neither Dig nor Vas separately increase Ex-EF vs DT alone. Dig+Vas combined ↑ Rst and Ex-EF vs DT, ↑ Rst-EF vs Vas and ↑ Ex-EF vs Dig (both p<.05). These data provide objective rationale for the chronic use of combined inotropic and vasodilator therapy in extreme LV dysfunction.

HEMODYNAMIC EFFECTS OF HYDRALAZINE IN PATIENTS WITH ISOLATED RIGHT VENTRICULAR FAILURE

Franklin Handel, MD; Robert H. Peter, MD, FACC; Lewis J. Rubin, MD, Duke University Medical Center, Durham, N.C.

Fifteen patients with isolated right ventricular failure secondary to pulmonary hypertension were evaluated for response to oral hydralazine(H). Three had idiopathic pulmonary hypertension, three closed ASDs, two closed VSDs, three COPD, two chronic pulmonary emboli, and two pulmonary fibrosis. All patients underwent right heart catheterization; none had LV dysfunction. Mean systemic pressure(MSP), mean pulmonary artery pressure(MPP), right atrial pressure(RA), right ventricular end diastolic pressure(RVEDP), pulmonary capillary wedge pressure(PCWP), cardiac index(CI), arteriovenous O_2 difference(AVO_2), heart rate(HR), total pulmonary resistance(TPR), and pulmonary arteriolar resistance(PAR) were measured for all patients at baseline(C). Rest studies (H) were then repeated after eight doses of 50 mg H orally q6h.

	MSP	MPP	RA	RVEDP	PCWP	CI	AVO_2	HR	TPR	PAR
R	99	62	15	17	9	2.2	8.0	87	19	12
Mean	±29	±23	±7	±5	±3	±.6	±2.3	±15	±14	±6
+S.D.	87	57	11	11	8	3.2	6.2	95	13	7
H	±23	±21	±6	±5	±3	±1.1	±2.0	±13	±11	±4
p	**	*	**	***	*	***	***	NS	***	***

p = *<.05; **<.01; ***<.001 by Student's two-tailed t test.

The above data suggests that oral hydralazine significantly increases cardiac output, lowers right ventricular end diastolic pressure, and lowers pulmonary vascular resistance in patients with right ventricular failure secondary to pulmonary hypertension.

INHIBITION OF NITROGLYCERIN EFFECT IN HUMANS BY SUPPRESSION OF PROSTAGLANDIN E

James Van Dusen, D.O.; Stephen J. Fischl, M.D., FACC; Overlook Hospital, Summit, New Jersey

10 healthy volunteers were studied supine using a mercury-in-rubber strain gauge plethysomograph and indwelling venous pressure cannula in the forearm. Volume-pressure characteristics of the forearm veins were determined using 15 second automatic cuff occlusions of the limb. Percent change of forearm volume (%ΔV) and change of venous compliance (C) were measured at rest and following 0.1 mg. sublingual nitroglycerin (NTG). Indomethacin (I) 150 mg. per day was administered to each volunteer for one week and the measurements were repeated.

The expected increments in limb volume and C during control cuff occlusions were 28% and 26% higher, respectively, after NTG. After I therapy and cuff occlusion, increments in limb volume and C were 25% and 39%, respectively, lower than control. While on I, mean increments in limb volume and C did not change significantly following NTG.

	15 second occlusion @ 40 mmHg			
	%Δ in volume		C(%Δ in volume/mmHg)	
Control	.32 ± .04	(p<.05)	.023 ± .007	(p<.05)
NTG	.41 ± .05		.029 ± .009	
I-Control	.24 ± .04		.014 ± .004	
I & NTG	.22 ± .04		.013 ± .013	

Therefore, augmentation of volume and compliance of the peripheral vasculature by NTG is inhibited by prior administration of I, presumably by suppression of prostaglandin E synthesis. This supports the concept that prostaglandins may be important mediators for the action of NTG in humans. Perhaps, patients receiving nitrates should be observed for this possible drug interaction with prostaglandin-inhibiting drugs.

VENTRICLES I: TACHYCARDIA AND FIBRILLATION
10:30-12:00

SIMULTANEOUS OPERATION OF MULTIPLE REENTRANT CIRCUITS DURING UNIFORM VENTRICULAR TACHYCARDIA

Benjamin J. Scherlag, PhD, FACC, Glenn Kabell, PhD, Johannes Brachmann, MD, Lura A. Harrison, PhD; Ralph Lazzara, MD, FACC. Veterans Administration Medical Center, University of Oklahoma, Oklahoma City, Oklahoma.

The association of reentrant ventricular tachycardia (VT) and continuous electrical activity (CEA) from the epicardium (epi) of the infarcted dog heart has been previously documented. In 14 dogs with 4 day old anterior wall myocardial infarction ECG leads, His bundle electrograms, epi and endocardial (endo) electrograms were recorded. Ventricular pacing, 3 beats at 300-420/min, was used to induce sustained VT with uniform QRS morphology in all 14 dogs either before (7 dogs) or after (7 dogs) administration of 2-6 mg/kg lidocaine. In 8 CEA was recorded only in the epi overlying the infarct during sustained VT. During VT in 2 dogs CEA was seen in both epi and endo recordings. However, the reentrant loop in the endo controlled the VT since CEA in the epi was intermittent but the endo CEA was constant and quantitatively linked to the R-R cycle length. In 3 dogs, during sustained VT, CEA in endo or epi coexisted with evidence of bundle branch macro-reentry in which the His and left bundle potentials were recorded between the QRS complexes. The underlying macro-reentry was unmasked when the CEA abruptly terminated. In 2 dogs, the epi CEA and QRS form during VT was replaced by an endo CEA pattern and different QRS form after lidocaine. With a higher dose of lidocaine, the induced VT showed portions of both epi CEA and endo CEA. The QRS form reflected the latter VT. We conclude that multiple reentrant loops, operating simultaneously, can be identified during uniform VT. The VT may be dominated by one circuit or may result from fusion of two circuits.

COMPARATIVE EFFECTS OF CYCLE LENGTH ON VENTRICULAR REFRACTORINESS OF NORMAL AND CHRONICALLY INFARCTED MYOCARDIUM

Eric L. Michelson, MD, FACC, Masahito Naito, MD, Joseph F. Spear, PhD, FACC, Daniel David, MD, E. Neil Moore, DVM, PhD, FACC. Lankenau Hospital and the University of Pennsylvania, Philadelphia, Pennsylvania

Although refractory periods(RP) measured in normal(N) ventricular muscle shorten when the pacing cycle length(CL) is decreased, the response of chronically infarcted(I), myocardium to CL changes is not known. This was evaluated in 13 dogs susceptible to pacing-induced sustained ventricular tachyarrhythmias(VT) studied $\geq$ 4 days after 2-stage coronary artery occlusion and reperfusion. Strength-interval curves were constructed at 24 N and 40 I intramyocardial sites during ventricular pacing at CL 500 msec and CL 300 msec using unipolar cathodal stimulation. Mean RPs measured using twice diastolic excitability threshold current(2x ET),5x ET, and 10 milliamps (ma) were compared:

Normal (msec)	RP(2x ET)	RP(5x ET)	RP(10 ma)
CL 500	195	189	178
CL 300	167	161	149
Infarct (msec)			
CL 500	239	227	218
CL 300	200	187	177

Thus, by decreasing the CL, mean RPs shortened to a similar extent at I($\geq$ 39 msec) and N($\geq$ 28 msec, p=NS) sites at each of these current intensities. However, even at shorter CLs, RPs at I sites remained markedly prolonged compared to N sites(difference $\geq$ 26 msec at CL 300, $p<0.001$). These findings suggest first, that in clinical electrophysiologic studies, one must consider the possible differences between N and I sites when interpreting the effects of various interventions on refractoriness; and second, that decreasing the CL may be an important means to facilitate initiation of those VTs requiring critically short coupling intervals, especially when pacing from areas of chronic infarction.

THE REPETITIVE EXTRASYSTOLE AS AN INDEX OF VULNERABILITY TO VENTRICULAR FIBRILLATION DURING MYOCARDIAL ISCHEMIA

Peter R. Kowey, MD; Richard L. Verrier, PhD, FACC; Bernard Lown, MD, FACC, Harvard School of Public Health and Harvard Medical School, Boston, MA.

The repetitive extrasystole threshold (RET) is a useful measure of vulnerability to ventricular fibrillation in the normal canine heart using the single stimulus technique. Whether this relationship obtains during graded degrees of myocardial ischemia has not been explored. In 13 chloralose-anesthetized dogs, left circumflex coronary blood flow (CBF) was decreased in a stepwise fashion using an externally-applied balloon occluder. There was a statistically significant correlation between the RET and ventricular fibrillation threshold (VFT) until coronary blood flow was reduced by 90% of control values ($r = .92$). With reductions of CBF greater than 90%, the RET/VFT ratio was disrupted.

CBF Reduction	RET (ma)	VFT (MA)	RET/VFT
Control	18 $\pm$ 1	30 $\pm$ 3	0.60
50%	13 $\pm$ 1*	22 $\pm$ 3*	0.59
75%	12 $\pm$ 1*	20 $\pm$ 3*	0.60
90%	14 $\pm$ 2*	16 $\pm$ 2*	0.88*

(*$P < 0.01$ compared with control)

Total coronary occlusion performed either abruptly or gradually (5 minutes) likewise increased the RET/VFT ratio. During total occlusion of one hour, the VFT recovered to control values within 15 minutes and the RET/VFT ratio was restored. We conclude that the elicitation of repetitive extrasystoles is a reliable index of vulnerability to VF which is not invalidated by near total occlusion of a major coronary vessel. It remains to be determined whether the disruption of the relationship is determined by the amount of ischemia produced or by other factors.

THE EFFECT OF INTERRUPTION OF COLLATERAL BLOOD FLOW ON CONDUCTION DELAY AND ARRHYTHMIAS DURING ACUTE MYOCARDIAL ISCHEMIA

David E. Euler, Ph.D., Charles E. Prood, M.A., E. Neil Moore, D.V.M., Ph.D., F.A.C.C. and Joseph F. Spear, Ph.D., F.A.C.C., University of Pennsylvania, Phila., Pa.

We studied the importance of collateral blood flow (CBF) on the genesis of epicardial conduction delay (ECD) and ventricular arrhythmias (VA) by comparing the electrophysiologic effects of coronary occlusion (CO) vs. coronary embolization (CE). In 23 open-chest anesthetized dogs, heart rate was held constant at 180/min and the proximal left anterior descending artery (LAD) was occluded for 10 minutes followed by 30 minutes of reperfusion. The LAD was then ligated and a rapidly hardening (10-20 sec) vinyl latex was injected just below the ligature. The latex filled all vessels branching from the LAD down to a diameter of 20-30 u. The amount of ECD was measured during atrial rhythm at 6 bipolar electrode sites located within the distribution of the LAD. The maximal ECD during CO was 97 $\pm$ 48 msec (mean $\pm$ SD) while CE increased the delay to 203 $\pm$ 51 msec ($p < .001$). During CO, 6% of the electrograms showed delayed activation occurring beyond the T-wave of the ECG while 28% of the electrograms showed post T-wave activation following CE ($p < .001$). During CO, 8% of the electrograms demonstrated alternation while 58% showed alternation during CE ($p < .001$). CO evoked ventricular fibrillation in 25% of the animals while no animal fibrillated following CE ($p < .001$). The results indicate that interruption of CBF to the ischemic myocardium increases the severity of local conduction abnormalities while reducing the incidence of lethal arrhythmias. The interruption of CBF may decrease the susceptibility of the ventricles to fibrillate by converting unidirectional block to bidirectional block.

ELECTRICAL INSTABILITY AS A FUNCTION OF MYOCARDIAL INFARCTION SIZE

Beverly A. Jones Collins, MD, Randolph E. Patterson, MD, FACC, Stephen E. Epstein, MD, FACC, NHLBI, Bethesda, Md.

The predisposing factors for post-infarction ventricular arrhythmias are ill-defined, and although indirect evidence supports the possibility that size of acute myocardial infarction is an important determining factor, no direct evidence exists. We therefore studied 13 conscious dogs 3 to 4 days after acute myocardial infarction was produced by closed chest coronary artery occlusion. The right ventricle was stimulated by a series of single, followed by double extrastimuli, scanning from end-diastole toward the T wave during right ventricle pacing. Abnormal responses included: repetitive ventricular responses (RVR), short runs of ventricular tachycardia (VT), sustained VT (SVT) and ventricular fibrillation (VF). An index of electrical instability was determined for each dog by the type of responses produced (score for VF>SVT>VT>RVR), the nature of the stimuli required to produce the responses (score for single>-double) and the time in diastole at which they could be elicited (score for late>early diastole). Myocardial infarction size was measured by post- mortem tetrazolium staining. Electrical instability correlated strongly with myocardial infarction size (r=.93). This is the first study utilizing direct measurement of myocardial infarction size to demonstrate that electrical instability several days post-AMI, as determined by electrical stimulation, is a function of myocardial infarction size.

MEOBENTINE SULFATE: ANTIARRHYTHMIC EFFICACY AND MECHANISM OF ACTION IN A CHRONIC CANINE MODEL OF MYOCARDIAL INFARCTION SUSCEPTIBLE TO VENTRICULAR TACHYARRHYTHMIAS

Eric L. Michelson, MD, FACC, Masahito Naito, MD, Daniel David, MD, E. Neil Moore, DVM, PhD, FACC, Leonard S. Dreifus, MD, FACC. Lankenau Hospital, Philadelphia, PA

The antiarrhythmic efficacy of meobentine sulfate(MBS), a non-neuronal blocking bethanidine derivative was evaluated in 6 open-chest pentobarbital-anesthesized dogs studied 4-6 days after 2-stage left anterior descending coronary artery occlusion and reperfusion. Prior to MBS, each dog was reproducibly susceptible to pacing-induced sustained ventricular fibrillation(VF,N=5 dogs)or tachycardia(VT, 1 dog). After intravenous infusion of 20 mg/kg MBS over 30 min, MBS demonstrated marked antiarrhythmic activity in each dog. In the 5 dogs with VF prior to MBS, VF re-initiation was prevented for a range of 5-12 hrs. In the one dog with VT prior to MBS,re-initiation of VT was prevented for 2hrs;VT then recurred at a slower rate until 6 hrs after drug infusion. This time course of antiarrhythmic activity paralleled the left ventricular tissue kinetics of MBS($T_{\frac{1}{2}}$ elimination=3 hrs) rather than its plasma concentration (α $T_{\frac{1}{2}}$ = 1.8 min, β $T_{\frac{1}{2}}$ = 90 min). Of note, MBS had no effect on the diastolic excitability threshold of either normal(N)or infarct(I)tissue at the time of its antiarrhythmic activity,but did prolong ventricular refractory periods(VRP)at both N(mean increase 25 $\pm$ 7(SD)msec at a paced cycle length of 300 msec,$p < 0.01$)and I sites(by 69 $\pm$ 23 msec, $p < 0.01$). Prolongations of VRPs at I sites were both more marked($p < 0.01$)and of longer duration (167 $\pm$ 71 min)than at N sites(120 $\pm$ 49 min,$p < 0.01$), and correlated with the time course of antiarrhythmic activity.Thus, MBS is an effective antiarrhythmic drug in this chronic model of inducible VT/VF and has a long duration of activity. Its mechanism of action appears to be related to myocardial drug uptake and prolongation of VRPs, particularly within areas of abnormal myocardium.

CARDIAC PACING
10:30-12:00

NON-INVASIVE SERIAL ELECTROPHYSIOLOGIC TESTING USING AN IMPLANTED PACEMAKER TO TRACK CHEST WALL STIMULI

Ross Fletcher, MD, FACC; John Keimel, MSEE, Lou Larca, MD; James Cox, MEEE; Albert Del Negro, MD; Robert Di Bianco, MD, FACC; Steve Singh, MD; VA Medical Center, Georgetown University, Washington, D.C.

A new technique for serial non-invasive electrophysiologic testing (EPT) was verified in 18 studies on 9 pts with an implanted multiprogrammable pacemaker * attached to ventricular (5pts) and atrial (4pts) leads. After programming ** the pacemaker to a triggered mode at outputs 2 times threshold, an external stimulator delivered premature impulses to the chest wall at outputs below patient perception thru electrode patches. External leads (6) and an esophageal lead determined responses.

The internal pacemaker tracked chest wall stimuli down to 220msec (the refractory period of the pacemaker). The effective refractory period of the ventricles (250$\pm$24msec) and atria (270$\pm$34msec) was longer than 220msec. Two ventricular pacemaker pts with clinical ventricular tachycardia had tachycardia induced with premature stimuli of 320msec and 330msec, and were reverted by tracking chest wall stimuli or programmed overdrive pacing. Three ventricular pacemaker pts without tachycardia had $\leq$ 2 repetitive beats following 1, 2 or 3 premature stimuli. Four atrial pacemaker pts had 6 supraventricular arrhythmias (4SVT, 2 atrial flutter) induced which were reverted by tracking chest wall stimuli (4) or rapid pacing (2). Repeat testing verified antiarrhythmic control after drug intervention in the 5/6 pts with arrhythmia.

Non-invasive serial EPT using permanent multiprogrammable pacemakers tracking chest wall stimuli is effective for inducing and reverting ventricular and atrial arrhytmias and in evaluating antiarrhythmic therapy.

A FIFTEEN YEAR COMPARATIVE STUDY OF CARDIAC PACING COSTS

Abe Lopman, BA; Clifford L. Langer, MBA; Seymour Furman, MD, FACC; Doris J.W. Escher, MD, FACC, Montefiore Hospital and Medical Center, Bronx, N.Y.

The total cost of treating the pacemaker (PM) patient (PT) has decreased by 46% from 1965-1980. Figures are based upon: costs in dollars per PT day, costs of PM, PM longevity, PT longevity, follow-up care (i.e. clinic visits, trans telephone monitoring (TTM) calls), and personnel costs in constant 1980 dollars (U.S. Bureau of Labor Statistics). At Montefiore Hospital and Medical Center, 50% cumulative survival is 8 years after initial implant. The following table describes changing costs for treating the PM PT for 8 years of care from the point of initial implant in 1965, 1970, 1975, and 1980.

	1980*	1975*	1970*	1965*
#PM/8 Yrs	1	2	3	4
PM Life-Each (mos)	96	43,96	37,37,43	18,18,37,37
Tot PM Cost ($)	2,729	4,904	5,391	6,276
Tot Days of Hosp	6.5	15	20	29
Tot Hosp $	2,600	6,070	6,468	6,089
Tot Prof Fees ($)	1,710	2,067	2,137	1,742
Tot Staff ($)	249	406	467	573
Tot Follow-up ($)	3,971+	6,348+	6,763	6,045
8 Yr Cost/PT	11,259+	19,795+	21,226	20,725
Cost/Yr/PT	1,407+	2,474+	2,653	2,590

* Year of implant; + Projected Cost

These data reflect the reduction in costs of contemporary cardiac pacing caused by the prolongation of the PM life span, transition from outpatient visits to the less expensive TTM follow-up and present TTM schedules, and to the reduction in hospital PT days, all producing a shift from a labor-intensive service, to a modern, cost-efficient, capital-intensive mode of care.

SINUS NODE DYSFUNCTION IN SPINAL CORD INJURY WITH QUADRIPLEGIA

Thomas A. Nicosia, MD, Peter Mercurio, MD, Frederick Feit, MD, FACC, Arthur C. Fox, MD, FACC, New York University Medical Center, NY, NY.

Patients with recent spinal cord injury and quadriplegia often demonstrate sinus bradycardia (SB), sinus arrest (SA), AV block, and hypersensitivity to vagotonic maneuvers. The presumed mechanism is interruption of the sympathetic nerves to the heart, with a relative increase in parasympathetic tone.

To determine the need for permanent pacing, we examined seven patients with recent spinal cord injury and quadriplegia prospectively, 1 to 2 weeks after injury. All patients had transient SB (35-60) and SA (2-8 sec). These episodes often occurred with nasotracheal suctioning, despite prior treatment with atropine and hyperventilation. In 5 of 7 patients, His-Bundle Electrograms and sinus node recovery times (SNRT)were determined and found to be normal (A-H=100±20 msec, H-V=44±5 msec, SNRT=110%±10% of resting cycle length). In 4 of 5 patients there was no disturbance in sinus node function with carotid sinus pressure, during nasotracheal suctioning or with hypoxemia. One patient had SA (4-6 sec) with carotid sinus pressure and during suctioning. 6 of 7 patients had later episodes of SA and SB requiring permanent pacemakers.

We conclude that there is marked temporal variability in sinus node dysfunction in patients with recent spinal cord injury and quadriplegia. A normal response to sinus node testing does not assure continued normal function. We, therefore, recommend permanent pacemaker insertion in patients with recent spinal cord injury with quadriplegia who have had significant SA or SB.

ASSESSMENT OF CLINICAL EFFICACY OF A MULTIPARAMETER PROGRAMMABLE PULSE GENERATOR

David L. Hayes, MD; James D. Maloney, MD, FACC; John Merideth, MD; David R. Holmes, Jr., MD, FACC; Bernard Gersh, MD, FACC; James C. Broadbent, MD; Michael J. Osborn, MD, FACC, Mayo Clinic, Rochester, Minnesota

Recent advances in pacemaker (PM) technology have provided noninvasively programmable pulse generators (PPG) which have the potential for solving PM system complications and providing a mechanism whereby the pulse generator can be adjusted to the specific needs of the patient without compromising reliability and longevity. To assess this problem, 40 consecutive patients (pts) receiving multiparameter PPG were analyzed as to initial indications, clinical application and reliability. Data analysis of these 40 pts demonstrated that 80% (32/40) had rate changes programmed, 25% (10/40) had pulse width changes and 10% (4/40) had sensitivity programming changes. Voltage amplitude programmability was utilized in 1 patient. Hysteresis and refractory period programmability were not utilized.

Utilization of programmable features included a change of one feature in 62.5% (25/40), two features in 15% (6/40), and three or more in 5% (3/40). This multiparameter unit clearly eliminated the need for reoperation in 2 pts. Although 90% of the programming changes (rate %/or pulse width) could have been accomplished with simpler units, sensitivity programmability solved PM problems in the remaining 10% (4/40). The increased complexity of the unit has not sacrificed reliability. Strict preimplant criteria for use of such a unit is difficult because of potential clinical flexibility of the unit.

NON-INVASIVE CORRECTION OF PACING SYSTEM MALFUNCTIONS BY MULTIPROGRAMMABLE PACEMAKERS.

Roger A. Billhardt, MD, Stuart W. Rosenbush, MD, and Robert G. Hauser, MD, Rush-Presbyterian-St. Luke's Medical Center, Chicago, Illinois.

Multiprogrammable pacemakers (M) may be useful for managing post-implant pacing system malfunction (F) without need for surgical intervention. Accordingly, we assessed the value of M for correcting F in 221 consecutive patients (pts) who received lithium M from 1/1/77 to 7/1/80. The mean implant time was 11.1±10.7 S.D. mos. All M were programmable for rate and energy output; also, 135 M had mode and 52 M had sensitivity programmable features. Of 18 pts who developed F from 1 day to 24.6 (mean: 3.9± 6.7) mos after implant, 61% (11/18) were corrected by programming (Pr) without reoperation (R). Six pts had failure to capture: 4 were corrected by Pr to higher output and 2 required R. Three pts had extracardiac muscle stimulation: 1 was resolved by Pr to lower output and 2 underwent R. One pt with failure to sense was successfully managed by Pr to higher sensitivity. Symptomatic myopotential inhibition affecting 3 pts was abolished by Pr to synchronous (1/3) and asynchronous mode (2/3). One pt with after potential oversensing was corrected by Pr to lower output. Of 4 pts with intermittent failure to sense and pace, 1 was corrected by Pr to higher output and sensitivity and 3 required R. All F eliminated by Pr continue to function normally from 0.7 to 27 (mean: 7.7±7.4) mos. The mean acute/chronic thresholds and R-wave amplitudes for pts who subsequently developed F were 1.3±0.8v and 7.8±2.2mv compared to 1.2±0.6v and 8.1±1.9mv for pts who did not develop F after implant (p>.1). The 7 pts with F not corrected by Pr required lead repositioning or replacement. During the study period $56,121 in hospital costs and fees were saved by successfully managing the 11 pts with F by programming. We conclude that M are potentially valuable for correcting F noninvasively. Thus, for a substantial number of patients who receive M, the discomfort and cost of surgical intervention will be avoided.

OPERATIVE REVISION REDUCTION WITH OUTPUT PROGRAMMABLE PULSE GENERATORS

Seymour Furman, MD, FACC; Frank Pannizzo, MS, Montefiore Hospital and Medical Center, Bronx, NY

To determine whether output programmable units (OPPG) have been of clinical value we investigated post implant threshold evolution. Four groups of threshold increases existed: 1) Progressive beyond any pacer output; 2) Progressive and stable above 25 microJoules (μJ) but below 100 μJ; 3) Early peak above 25 μJ with return to a level above 10 μJ; 4) Early peak above 25 μJ with later return to "normal" chronic levels below 10 μJ. A significant increase in threshold was considered one which exceeded the energy output of a 5 volt, 0.5 milliseconds (ms) pulse duration pulse generator (PG) current limited to 10 milliamperes or a total output of 25 μJ. The output levels of each PG for initial (first implant or new lead placement) implant was calculated. For the OPPG whenever threshold exceeded 25 μJ it was assumed that cardiac stimulation would have stopped if output had not been increased. For the fixed output units, cessation of pacing was determined electrocardiographically. In 312 initial implants 30 revisions or 9.6% were performed for failure to stimulate without obvious lead displacement, facture, etc. Of 289 initial programmables, 13 required revision, or 4.5% patients with OPPG required increase in output to avoid intervention. This is a significant difference ($p = 0.15$). Output programmability provides a significant advantage for avoidance of implant revision.

CLINICAL EVALUATION OF LEFT VENTRICULAR FUNCTION
10:30-12:00

AN AUTOMATED METHOD FOR LEFT VENTRICULAR VOLUME MEASUREMENT FROM THE CINEVENTRICULOGRAPHY WITH MINIMAL DOSES OF CONTRAST MEDIUM

Masatoshi Fujita, MD; Shigetake Sasayama, MD; Hiroshi Nonogi, MD; Chuichi Kawai, MD, FACC; Shigeru Eiho, PhD; Michiyoshi Kuwahara, PhD, Otowa Hospital, Kyoto, Japan

Cineventriculography is of considerable value for the dimensional analysis of the left ventricular cavity(LVC), however, conventional methods necessiate the injection of large amounts of contrast medium(CM). To minimize the untoward effects of CM, we obtained left ventriculogram(LVG) using only 5 ml of the dye. We also developed a computer aided image processing system to enhance the contrast of the ventricular image by subtracting the reference image to eliminate irrelevant background material. The boundary of LVC was automatically determined to calculate the instantaneous volume change throughout the cardiac cycle. Using this small doses of dye, the elevation of the left ventricular end-diastolic pressure(LVEDP) which consistently occurred at 1 to 3 minutes after injection of the conventional large doses could be avoided (LVEDP at 1 minute after dye injection being averaged 11.8±4.9 vs 19.1± 6.1 mm Hg). Values for end-diastolic volume, end-systolic volume and ejection fraction calculated from the two consecutive LVG in 17 patients were similar (99±21(SD) vs 99± 22ml, 32±20 vs 34±23ml, and 66±12 vs 66±13% respectively). Thus, the small dose of CM provides for an accurate measurement of the left ventricular dimension and function without significant hemodynamic derrangement, and minimizes the additional risk to the patient undergoing examination under varying physiologic conditions. The advantage of easy repeatability of this method can be further applied to determine the optimal projections for assessing regional abnormalities of wall motion in ischemic patients with multiple exposures at various degrees of obliquity.

A NEW TECHNIQUE FOR THE SIMULTANEOUS ASSESSMENT OF MYOCARDIAL PERFUSION AND CONTRACTILITY IN MAN

Oberdan Parodi, MD; Walter Bencivelli, Dr; Paolo Camici, MD; Paolo Marzullo, MD; Graham J. Davies, MD; Attilio Maseri, MD, FACC; Antonio L'Abbate, MD, FACC.
CNR Institute of Clinical Physiology, Univ. of Pisa, Pisa, Italy

Radiolabelled human albumin microspheres (HAM) were used in the past to visualize coronary flow distribution in man. We applied gated reconstruction to HAM images to obtain information both on myocardial perfusion (MBF) and on contractility (Cy). HAM (2.5 millions sizeing 18±10 u Ø) labelled with 13 mCi of 99mTc, are injected into the LV during cardiac catheterization. Contrary to intracoronary injection, LV injection ensures homogeneous mixing of tracer and HAM distribution proportional to regional MBF. Data are collected in list mode and reconstructed off-line: this allows optimization of reconstruction parameters and the study of short duration events. By this technique, we studied as a preliminary, 15 patients with variable degree of coronary heart disease. The pattern of Cy of myocardial walls was in agreement with that observed by contrast ventriculography and by echo. The Cy of scar unperfused walls was missed: however, in these cases the main interest lies in the residual Cy of perfused walls. Advantages of the technique are: a) simultaneous information on MBF and Cy: b) prolonged time for Cy observation (4 to 6 hours); c) high quality pictures due to the favourable signal to background ratio; d) potential information on wall thickness. HAM scintigraphy gives: 1) relative to 201-Tl, a steady, true MBF pattern not affected by reperfusion or metabolism and a better imaging definition; 2) relative to gated blood pool imaging, higer quality pictures of Cy and simultaneous evaluation of MBF.

EFFECTS OF VERAPAMIL AND NIFEDIPINE ON LEFT VENTRICULAR FUNCTION IN PATIENTS WITH PRINZMETAL'S VARIANT ANGINA.

SM Johnson MD, DR Mauritson MD, J. Corbett MD, GJ Dehmer MD, JT Willerson MD, FACC, LD Hillis MD, FACC. U. of Texas Health Science Center at Dallas, Dallas, Texas.

We assessed the effects of verapamil (V) and nifedipine(N) on LV function at rest and during exercise in patients(pts) with variant angina pectoris (VAP). Each of 10 pts (6 men 4 women, mean age 52 yrs) was treated for 2 month periods with placebo(P1), V(400±80mg/day, mean±SD), and N (82±31 mg/day); 8 were maintained throughout the study on stable doses of isosorbide dinitrate(138±56 mg/day). Prior to study, all were catheterized: 8 had no fixed coronary artery disease (CAD), 1 had single vessel CAD, and 1 had 3 vessel CAD. One pt had 3 prior myocardial infarctions presumably due to coronary artery spasm. No pt had congestive heart failure clinically. The resting LV ejection fraction (EF) during P1 ranged from 26 to 84%. In each pt, equilibrium gated blood pool scintigraphy was performed at rest and during supine bicycle exercise during the final week of each of the three 2-month treatment periods. The following were measured at rest and with Ex: (1)peak achieved work load (PAWL), (2)heart rate (HR), (3)systolic blood pressure(SBP), (4)end-diastolic volume index, (5)end systolic volume index(ESVI), and LV EF.

	PAWL(kpm)	HR at PCL	ESVI at PCL	Rest EF	EF at PCL
P1	360±128	127± 9	26±25	61±18	70±19
V	357± 98	118±11	32±30	63±17	68±16
N	355±135	127±10	33±49	67±17	75±19

At rest and during the peak work load common to all 3 Ex tests(PCL), neither V nor N affected any of the measured variables. Thus, in patients with variant angina and a wide range of LV function at rest, neither verapamil nor nifedipine significantly alters exercise performance, nor do these agents adversely affect LV volumes or LV EF at rest and during exercise.

PRESERVATION OF INTERVENTRICULAR SEPTAL FUNCTION IN PATIENTS HAVING CORONARY ARTERY BYPASS GRAFTS WITHOUT CARDIOPULMONARY BYPASS

Cary W. Akins, M.D.; Charles A. Boucher, MD, FACC; Gerald M. Pohost, MD, FACC; Massachusetts General Hospital, Boston, Mass.

Abnormal interventricular septal motion develops in the majority of patients after cardiac surgery. It has been attributed by others to leaving the pericardium open or to septal ischemia. This study assesses the role of cardiopulmonary bypass in the genesis of abnormal septal motion. Eighteen patients having single coronary artery bypass grafts (CABG) to the left anterior descending or right coronary artery had septal motion evaluated pre- and postoperatively. Nine patients who had CABG with CPB were compared to 9 patients who had CABG without CPB. Patients who had normal or mildly hypokinetic septal motion before surgery, as assessed by resting gated blood pool scan or ventricular angiography, were scanned again prior to hospital discharge. Septal motion was graded as normal, hypokinetic, akinetic or dyskinetic by three independent observors.

Postoperatively all 9 patients having CABG with CPB had diminution of septal function with frank septal akinesis or dyskinesis in 7 (78%). Eight of 9 patients having CABG without CPB had no change or improvement in septal motion with only one patient developing mild hypokinesis ($p < .001$). No patient had a perioperative myocardial infarction, and in all the patients the pericardium was left open.

This study suggests that the development of abnormal septal motion in patients having single CABG is related to differential septal ischemia due to the use of CPB and/or the techniques of myocardial preservation but not to the CABG procedure itself or to leaving the pericardium open.

THE SYMPATHETIC RESPONSE TO EXERCISE IN PATIENTS WITH CONGESTIVE HEART FAILURE

Gary S. Francis, MD, FACC; Steven R. Goldsmith, MD; Jay N. Cohn, MD, FACC, University of Minnesota and the V.A. Medical Center, Minneapolis, Minn.

To assess the sympathetic response to exercise in congestive heart failure (CHF) we measured plasma norepinephrine (NE) and epinephrine (E) at rest and during maximal (max) upright bicycle exercise in 14 patients (pts). The results were compared to 6 normal subjects. Pts were in a steady state off diuretics and vasodilators. NE and E were measured using a radioenzymatic technique. Samples were taken with pts upright just prior to exercise (ex) and during peak ex. Ex capacity was determined by measuring max oxygen consumption ($\dot{V}O_2$ max). Pts were class II-IV and all had evidence of poor left ventricular (LV) function by radionuclide ejection fraction (22 ± 2.4%, SEM) and by echo (% shortening minor axis 15 ± 1.8%). $\dot{V}O_2$ max averaged 10.06 ± 1.4 ml/kg/min. The control upright NE was 636 ± 93 pg/ml and increased 171% to 1721 ± 198 pg/ml with peak ex. Plasma E increased 83% from 92 ± 18 pg/ml to 167 ± 26 pg/ml. The six normal control subjects increased NE 913% with ex (318 ± 36 pg/ml to 3220 ± 418 pg/ml), which is markedly different than pts with CHF ($p<.001$). Controls increased E 707% with ex (92 ± 26 pg/ml to 742 ± 210 pg/ml), which is also different than pts with CHF ($p<.01$). The increase in NE (% ΔNE) during ex correlated well with $\dot{V}O_2$ max ($r=.78$, $p<.001$) in pts with CHF, but % ΔE did not ($r=.23$). Catecholamines do not therefore increase to the same extent with max ex in pts with CHF as they do in normals, despite higher basal levels in heart failure pts. The ability of pts with heart failure to release NE with ex parallels their functional capacity as measured by $\dot{V}O_2$ max.

IS ISOVOLUMIC RELAXATION IMPAIRED IN SECONDARY HYPERTROPHY?

Peter Eichhorn,MS; Herta Zuend; Rosmarie Koch; Otto Hess, MD; Hans P.Krayenbuehl,MD, Medical Policlinic of the University, Zurich, Switzerland.

The speed of LV isovolumic relaxation was estimated in 56 patients (pts) with aortic valve disease (AVD) (21 AS, 18 AS+AI, 17 AI) and in 5 control subjects (group C). Pts with coronary artery disease were excluded. In all pts LV micromanometry simultaneous with single beam echos was carried out.Peak neg.dP/dt and peak neg.dS/dt (S = meridional wall stress) were used as indices of LV relaxation. Angiographic LV muscle mass was increased ($P<0.001$) in AS (179 g/m^2), AS+AI (220) and in AI (213) as compared to C (76).Peak neg.dP/dt amounted to 1491 mmHg/sec in C and did not differ from the values in the three groups of AVD although LV peak systolic pressure was higher in AS (209 mm Hg, $P<0.001$), AS+AI (190,$P<0.001$) and AI (144,$P<0.01$) than in C (114). In contrast peak neg.dS/dt was increased in AS ($1403 \cdot 10^3$ dynes/sec/cm^2, $P<0.05$), AS+AI (1467, $P<0.005$) and AI (1355, $P<0.02$) as compared to C (788). LV peak systolic S was however increased in AVD ($257 \cdot 10^3$ dynes/cm^2 in AS, $P<0.01$; 257 in AS+AI, $P<0.01$; and 212 in AI, $P<0.025$) when compared to C (128). Linear regression analysis between peak neg.dS/dt and peak S yielded significant correlations in C ($r=0.98$), in 26 pts with AVD and normal LV systolic function ($r=0.79$) and 30 pts with depressed (biplane ejection fraction <0.56, Vpm <1.14 ML/sec) LV function ($r=0.80$). Slopes and intercepts of these three regressions were similar. It is concluded that (1) in contrast to peak neg.dP/dt peak neg.dS/dt does not indicate impaired relaxation in secondary hypertrophy from AVD and (2) peak neg.dS/dt is determined by peak S regardless of the actual level of systolic LV function.

PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOPLASTY
10:30–12:00

CLINICAL EXPERIENCE WITH A NEW CATHETER SYSTEM FOR PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOPLASTY

John B. Simpson,M.D; Ned Robert, M.D.; Donald Baim,M.D.; Donald C. Harrison, M.D.,Stanford University Medical Center, Stanford, CA. 94305

A new catheter system designed with a movable guide wire, and permitting rapid manual balloon inflation and deflation, has been used to perform percutaneous transluminal coronary angioplasty (PTCA) in 35 patients over the past 18 months. During this period, further design improvements have reduced the diameter of the 3 mm low-profile balloon catheter from 0.049" to 0.036" (tip), from 0.058" to 0.042" (collapsed balloon), and from 0.069" to 0.059" (shaft). This low-profile configuration is well suited for PTCA of high-grade stenoses of the left anterior descending, in which successful PTCA was performed in 14 of 15 patients (93%), with a reduction of the mean pre-PTCA stenosis from 89 ± 12% (range 70-99%) to a mean post-PTCA stenosis of 41 ± 24% (range 10-55%)*. No emergency coronary bypass operations were required, and there was no evidence of myocardial infarction. Restenosis at the site of successful PTCA developed in two patients (14%) -- both were successfully redilated. The mean followup period is 5.2 months (range 1-9 months). The success rate of 93% with the low-profile catheter represents a substantial improvement over the success rate of 54% with the standard profile catheter in similar lesions.

We conclude that the use of this catheter system allows safe and effective dilatation of even high-grade stenoses of the left anterior descending coronary artery, with relief of the clinical symptoms of myocardial ischemia.

* $p < 0.001$, student's paired t-test

ACUTE AND CHRONIC EFFECTS OF TRANSLUMINAL ANGIOPLASTY IN EXPERIMENTAL ATHEROSCLEROSIS

Vance J. Weber, MD; David P. Faxon, MD, FACC; Christian Haudenschild, MD; Susan B. Gottsman, AS; Wanda A. McGovern, BA; Thomas J. Ryan, MD, FACC, Boston University School of Medicine, Boston, MA

Transluminal angioplasty (TA) has received considerable attention in the treatment of obstructing atherosclerotic lesions in man; however, its mechanisms of action and effects remain unclear. To evaluate the acute and long-term consequences of TA, 30 rabbits were examined using 3 experimental models of atherosclerosis: high cholesterol diet (HCD) plus balloon de-endotheliaization (n=18); HCD plus an indwelling catheter (IC) (n=7); normal diet plus IC (n=5). Angiographic increase in luminal diameter was accomplished in 21 of 30 rabbits. In vessels showing > 50% change in luminal diameter by angiogram, (n=14), pathological examination one day after TA revealed: 1) for concentric lesions: total rupture of the intima, medial compression with disruption of the internal elastic lamina, marked inflammation and frequent thrombosis; 2) for eccentric lesions: thinning and necrosis predominantly of the normal portion of the vessel wall. Angiographic changes in luminal diameter of less than 50% were not associated with consistent histopathologic findings. In 11 rabbits examined 2 or 4 weeks after TA, further remodeling of the intima was suggested by the presence of additional loose fibrous tissue, and thrombi in various stages of organization and recanalization.

In summary, in these experimental models of TA: 1) dramatic intimal rupture, medial damage and inflammation often result; 2) proliferating intimal processes leading to luminal narrowing continue after TA; 3) marked destruction to the normal vessel wall may occur; and 4) angiographic appearance usually correlates with histopathologic findings of TA effects.

BENEFICIAL RESULTS FROM TRANSLUMINAL CORONARY ANGIOPLASTY ASSESSED BY QUANTITATIVE CROSS-SECTIONAL CORONARY ARTERIOGRAPHY

Robert K. Mito, M.D., Albert E. Raizner, M.D., FACC, John M. Lewis, M.D., FACC, William L. Winters, Jr., M.D., FACC, Richard R. Miller, M.D., FACC, Baylor College of Medicine and The Methodist Hospital, Houston, Texas.

Transluminal coronary angioplasty is a relatively new procedure, the efficacy of which is not firmly established. Quantitative assessment of stenosis severity and effects of dilatation is needed to more accurately measure its effects. Consequently, a technique of quantitating cross-sectional stenosis and normal lumen area using biplane measurements and computing area based on an elliptical model $[(a/2)^2 \times (b/2)^2 \times \pi]$ (a = short axis and b = long axis) was applied to eight patients (four native coronaries and four bypass grafts) who underwent "successful" coronary angioplasty. Before angioplasty, mean cross-sectional stenosis area was 1.36 mm^2 (range 0.45 to 2.57 mm^2) and cross-sectional percent stenosis was 84.5% (range 63.7 to 95.1%). Trans-stenosis gradient was present in seven of eight and ranged from 5 to 65 mmHg (mean 27.1 mmHg). Following angioplasty, mean cross-sectional stenosis area was 5.28 mm^2 (range 2.08 to 17.12 mm^2) ($p < .05$ from preop) and cross-sectional percent stenosis was 47.5% (range 1.3 to 85%) ($p < .01$). Mean percent improvement in stenosis was 37.0% (range 9.1 to 90.1%). Concomitantly, trans-stenosis gradient was eliminated in six of the seven patients with pre-angioplasty gradients.

Thus, improvement in stenosis severity can be documented by quantitative cross-sectional coronary arteriography and reflects hemodynamic improvement. This arteriographic technique may be applied in the serial evaluation of coronary angioplasty patients.

LEFT VENTRICULAR FUNCTION BEFORE AND AFTER SUCCESSFUL CATHETER DILATATION OF CRITICAL CORONARY STENOSES

Ulrich SIGWART MD, FACC, Milan GRBIC MD, Axel ESSINGER MD, Angelika BISCHOF-DELALOYE MD, Hossein SADEGHI MD, Jean-Louis RIVIER MD, FACC. - Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Left ventricular (LV) function was studied in seven patients one day before and six months after successful catheter dilatation(D) of critical LAD stenoses. LV and AO pressures with tipmanometers and thermodilution cardiac output were taken at rest (R) and during submaximal bicycle exercise (E) in the supine position as well as during isoproterenol (I) infusion. Ejection fraction at R and during E was estimated by gated blood pooling scintigraphy.

Hemodynamics at R before and 6 months after dilatation were not significantly different. LV EDP during E was 35.8±4.5mmHg before and 20.1±2.8mmHg 6 months after D. LV SVI at E augmented from 79±11 to 110±15ml. per beat after D. LV dP/dt max. failed to change significantly but dP/dt min. normalized from -1550±95 to -2000±110mmHg /sec. during E suggesting improved relaxation. DPTI/SPTI ratio was 0.5±0.15 before and 0.8±0.1 after dilatation, and during I abnormal LV contractility parameters improved as well. LV ejection fraction at R was normal and not significantly different before and after D ; exercise ejection fraction, however, improved after dilatation from 52±7.8% to 63±6.4%.

It is concluded that E tolerance and parameters of left ventricular function during dynamic E can be improved in patients after successful D of critical LAD stenoses.

EVALUATION OF TRANSLUMINAL CORONARY ANGIOPLASTY IN LEFT MAIN CORONARY ARTERY STENOSIS

Simon H. Stertzer, MD, FACC; Eugene Wallsh, MD, FACC; Michael S. Bruno, MD., Lenox Hill Hospital, New York, NY

Eight attempts at transluminal coronary angioplasty (PTCA) were made in left main coronary artery stenosis (LMCAS) over a 27 month period. There were 7 males and 1 female; mean age 51 years (range 45-54). All patients had multivessel coronary artery disease. Three patients had previously undergone open heart surgery (2, coronary bypass surgery (CABG); 1, aortic valve replacement). Six patients underwent PTCA via the brachial approach while 2 were treated by the femoral. All patients had Canadian Heart Class (CHA) III or IV anginal syndromes. One patient had severe preinfarctional angina requiring intraaortic balloon support. All 8 left main orifices were entered with the guiding catheter. All 8 lesions were passed with the dilatation catheter. All left main stem lesions improved initially angiographically. Mean percent stenosis before angioplasty was 75% (range 60 to 90). Mean increase in coronary distal pressure after PTCA was 48 mm Hg (range 33 to 65 mm Hg). Mean percent stenosis after left main PTCA was 32% (range 5 to 60%). All patients improved at least 1 CHA class after PTCA, and 4 were Class I. No patient died or required emergency operation. Two patients (25%) experienced recurrence within 12 months. Three patients in all required delayed CABG surgery either because of residual left main stem stenosis, recurrence, or because of remote multivessel disease. Two patients improved markedly with PTCA after CABG alone did not satisfactorily relieve their angina. The preinfarctional patient with IABP avoided surgery completely. It is concluded that despite concern regarding PTCA in LMCAS the procedure is feasible without increased risk in selected cases.

NATIONAL HEART, LUNG AND BLOOD INSTITUTE REGISTRY REPORT OF COMPLICATIONS OF PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOPLASTY

Gerald Dorros, MD, FACC; Michael Cowley, MD, FACC; John Simpson, MD; Members of Executive Committee of NHLBI-PTCA Registry, Lutheran Hospital of Milwaukee, Inc., and Medical College of Wisconsin, Milwaukee, Wisconsin.

Since September, 1977, data have been collected on 632 patients (pts) who have undergone percutaneous transluminal coronary angioplasty (PTCA) from 34 centers. There were 664 PTCA's attempted with 393 (59.2%) primary successes. In 123 (19.5%) pts, there were 152 (22.9%) complications, 57 (8.6%) with sequelae and 95 (14.3%) without sequelae. The 57 complications with sequelae occurred in 52 pts (8.2%) and included: hospital deaths in 6 (0.9%) (1 directly related, 4 probably related, and 1 unrelated to PTCA); myocardial infarctions (MI) in 23 (3.5%): 11 MI's in pts with, and 12 MI's in pts without coronary artery bypass surgery (CABG) within 24 hours; coronary occlusion in 18 (2.7%); vascular complications requiring surgery in 8 (1.2%); and others, 3 (0.5%). The 95 complications without sequelae occurred in 71 (11.2%) pts and included: coronary artery dissection in 22 (3.3%); prolonged angina in 18 (2.7%); bradycardia requiring therapy in 12 (1.8%); coronary spasm in 12 (1.8%); hypotension requiring therapy in 9 (1.3%); ventricular fibrillation in 7 (1.1%); excessive blood loss in 7 (1.1%); ventricular tachycardia in 3 (0.5%); and others, 5 (7.5%). CABG was performed on 108 pts within 24 hours. There were 44 (7.0%) emergency pts, with evidence of a MI developing in 10 (22.7%). There were 64 (10.1%) elective pts. The incidence of complications occurring with PTCA, to date, is not negligible, even though the complications with sequelae are less than 10%. The mortality and morbidity with PTCA appears comparable to those reported with CABG.

VENTRICULAR TACHYCARDIA/FIBRILLATION: PREDICTION/ TREATMENT
10:30-12:00

PROGNOSTIC VALUE OF VENTRICULAR ARRHYTHMIAS
Robert M. Califf, M.D., Galen S. Wagner, M.D., Robert A. Rosati, M.D., Duke University, Durham, North Carolina

This study was designed to determine whether ventricular arrhythmias(VA) predict decreased survival independently of their association with extensive coronary artery disease(CAD) and poor LV function. Ambulatory monitoring was done for 24 hours in 611 medically treated patients after catheterization for suspected CAD. VA were grouped by modified Lown grade: 0-no VA; 1-peak hourly premature ventricular contractions(PVC's)<30: 2-peak hourly PVC's ≥30; 3-multiform PVC's; 4-2 consecutive PVC's; 5- ventricular tachycardia. Patients with higher grades had lower ejection fractions($p<.01$) and decreased survival($p<.01$).

Grade	PTS	Mean Ejection Fraction	Survival lyr.	Survival 3yrs.
0-1	363	57	98%	95%
2-3	179	51	93%	86%
4-5	69	41	82%	69%

A score based on VA grade was the most potent predictor of cardiovascular death among descriptors of VA($X^2=32$). When considered with a group of 20 catheterization measurements in multivariable analysis, VA had no independent prognostic significance. LV end diastolic pressure and number of vessels with ≥75% stenosis were the most powerful predictors in multivariable analysis.

In the 361 patients with normal LV contraction, VA grade was not related to survival.

Grade	PTS	Survival lyr.	Survival 3yrs.
0-1	260	99%	98%
2-3	84	98%	98%
4-5	17	100%	92%

In these patients with symptoms of CAD, VA were associated with decreased survival because they reflected advanced CAD and LV dysfunction. A group with normal LV function at risk due to VA could not be identified.

PREDICTIVE VALUE OF PROGRAMMED ELECTRICAL STIMULATION IN PATIENTS WITH SUDDEN DEATH OR RECURRENT VENTRICULAR TACHYCARDIA. Edward V. Platia, MD, Stephen C. Vlay, MD, Philip R. Reid, MD, FACC. Johns Hopkins University, Baltimore, Maryland.

Programmed electrical stimulation (PES) was carried out in 48 patients (pts) referred for evaluation of sudden cardiac death(SD) (17 pts) and/or recurrent ventricular tachycardia (VT) (30 pts) and in 11 controls. PES included: 1)single ventricular premature depolarization(PVD) after atrial drive(A_1V_1);2) single PVD following V drive (V_1V_2); 3) double PVDs following V drive ($V_1V_2V_3$); and 4) rapid V pacing for 10 consecutive beats (V_{burst}). At least 3 quadripolar catheters were used:right atrial, right and/or left ventricular and His catheters. A positive response was defined as 2 or more ventricular premature beats produced by the final ventricular pacing stimulus occurring by intraventricular reentry. Forty SD/VT pts underwent PES with the $V_1V_2V_3$ technique and 17 of 28 with a positive test by this technique,including 6 pts with sustained VT, had SD or recurrent VT following hospital discharge, while only 1 of 12 with a negative test had SD or recurrent VT in follow-up(range 1-13 months)($p\leq.007$). None of the 11 control pts had a positive response with any technique. The positive predictive value (PPV) was therefore 61%, while the negative predictive value was 92%. Twenty-eight of the 40 pts were found to be on the same drug regimen in follow-up as during PES. Of this group, subsequent SD or recurrent VT occurred significantly more frequently (PPV=71%) if electrophysiologic testing with $V_1V_2V_3$ technique yielded a positive result (15 of 21) compared to a negative result (1 of 7)($p\leq.03$). The other 3 techniques, A_1V_1, V_1V_2, and V_{burst} were not significantly predictive of subsequent SD or VT, the PPVs being 22%,47% and 50% respectively. In conclusion, in pts with a history of sudden death or recurrent ventricular tachycardia, PES carried out with the $V_1V_2V_3$ pacing technique is predictive of the occurrence of subsequent sudden death or ventricular tachycardia and appears to be superior to the A_1V_1, V_1V_2 and V_{burst} techniques.

PREVALENCE AND SIGNIFICANCE OF VENTRICULAR TACHYCARDIA IN THE LATE HOSPITAL PHASE OF MYOCARDIAL INFARCTION
J. Thomas Bigger, Jr., MD, FACC; Francis M. Weld, MD, FACC: Linda M. Rolnitzky, MS, Columbia University, New York, N.Y.

There are no large studies which determine the significance of ventricular tachycardia (VT) two weeks after myocardial infarction (MI). Accordingly, we evaluated the prevalence and significance of VT in 430 MI patients studied just before discharge from hospital. A 24-hour Holter ECG was recorded and analyzed by digital computer. Fifty patients (11.6%) had VT. The VT group had significantly more :previous MI; LV failure, atrial fibrillation and VT/VFIB in the CCU; and more posthospital treatment with digitalis, diuretics and antiarrhythmic drugs. There was no significant association between age, site of MI or peak creatine kinase and the occurrence of VT. Only a single episode of VT occurred in 25 patients (50%); the average number of episodes was 21±72. The longest run of VT was only three complexes in 16 patients (32%). The average number of QRSs in VT was 11±35. The average rate of VT was 123±33 beats/min and R on T started VT in only three patients (6%). The correlation between VT and heart rate was not significant ($r=0.14$). There was no relationship between time of day and occurrence of VT. In the first year after MI, 64 deaths occurred (15%). Mortality in the VT group was 40% compared to 12% in the non-VT group. VT had the strongest association with one year mortality of any variable examined. Also, the association of VT with death was independent of many other risk factors. We conclude that asymptomatic, self-limited VT is a specific, potent and independent risk factor for death in the year after MI.

ELECTROPHYSIOLOGIC STUDIES BEFORE AND AFTER IMPLANTATION OF THE AUTOMATIC DEFIBRILLATOR. Philip R. Reid, MD, FACC; M. Mirowski, MD, FACC; Morton M. Mower, MD, FACC; Stephen C. Vlay, MD, Edward V. Platia; Myron L. Weisfeldt, MD, FACC. Johns Hopkins Hospital and Sinai Hospital, Baltimore, Maryland.

Programmed electrical stimulation (PES) studies were performed in a group of 6 patients (pts)(age 16-72 years) who underwent implantation of the automatic defibrillator (AD) in order to determine their suitability as candidates for implantation and to evaluate AD performance post-operatively. All pts were survivors of multiple episodes of sudden cardiac death and were refractory to conventional and investigational drug therapy. The 4 PES studies which were done prior to AD implant demonstrated easily inducible sustained or nonsustained ventricular tachycardia or flutter (VT/VF). After AD implant PES was performed in 5 pts (one pt developed spontaneous VT post-op which obviated need for PES), using either standard PES techniques or a train of impulses (60-100Hz)if needed, resulting in hypotensive VT/VF (333 to 222ms) which were similar to the native dysrhythmias. The AD identified the arrhythmias in all cases and discharged after an average of 30.8sec (range 18-50 sec.),restoring a normal rhythm in 3 cases. In two pts, the induced VT/VF was not corrected on the initial automatic countershock and external cardioversion was successfully used. One of these two pts subsequently died with presumed out-of-hospital sudden death which may indicate the need for higher defibrillation energy requirement. In the second pt, review of electrograms raised question of low-level 60Hz interference which could alter AD function. In 2 pts, 7 episodes of VT occurred spontaneously, all of which were correctly identified and converted by the AD. These preliminary studies demonstrate that the AD is capable of correctly identifying and converting potentially lethal VT/VF and that PES in these high risk pts may offer a safe and useful adjunct to AD evaluation.

Low Energy Versus High Energy Defibrillation in the Treatment of Out-of-Hospital Ventricular Fibrillation. A Preliminary Report.
W.Douglas Weaver,MD,FACC;Leonard A.Cobb,MD,FACC;Michael K. Copass,MD;Alfred P.Hallstrom,PhD,University of Washington, Seattle, WA.

The efficacy of defibrillation using 175J was prospectively compared to 320J in 95 victims of ventricular fibrillation (VF) treated outside the hospital. By random allocation, 46 patients (pts) received 175J and 49 received 320J for the first two shocks; all subsequent shocks were 320J in both groups. Ten of the 175J group (22%) and 8 of the 320J group (16%) persisted in VF through two shocks. Twenty-nine pts in each group were resuscitated and transported to the hospital. Fourteen of 38 pts (37%) in the 175J group and 12 of 41 (29%) in the 320J group survived and returned home (8 in each group are still hospitalized). The 175J group received an average of 4.7 shocks compared to 3.4 in the 320J group ($p < 0.05$); but this difference occurred only in non-resuscitated pts (6.6 vs 4.0 shocks in the 175J vs the 320J group respectively, $p < 0.025$). Pts discharged alive (both groups) received fewer shocks than did those who were resuscitated and later died in the hospital, (2.4 vs 4.6, $p < 0.005$). At the end of the two shock trial, the ECG showed the following rhythms in the 175J and 320J groups: VF 35% vs 20%; asystole 7% vs 20% ($p < 0.05$); idioventricular 15% vs 16%, and supraventricular 43% vs 43%. Following the first two shocks, 3 pts (7%) in the 175J group compared to 10 (20%) in the 320J group had demonstrated high degrees of AV block ($p < 0.05$).

We conclude that two low energy shocks appear to be safe in the treatment of out-of-hospital VF, that outcome appears at least as good as that obtained with 320J, and that there may be less cardiotoxicity as measured by resulting asystole and AV block.

TWO DIMENSIONAL ECHOCARDIOGRAPHY OF THE HEART DURING CARDIOPULMONARY RESUSCITATION IN MAN
Stuart Rich, MD; Hershel L. Wix, MD; Edward Shapiro, MD, University of Chicago, Chicago, Illinois.

Recent animal studies have challenged the notion that compression of the heart between the sternum and spine causes blood flow during closed chest CPR. We performed 2-D echocardiography (2DE) within 20 minutes after the initiation of CPR in four patients (ages 58-84 yrs., 3 with coronary artery disease, 1 with congestive cardiomyopathy) who had cardiac arrest while in the intensive care unit. Each patient had arterial pressure monitoring that confirmed the effectiveness of the CPR. None of the patients survived resuscitation. Analysis of the 2DE showed that the mitral and aortic valves were open simultaneously during the compression phase, suggesting blood flow directly from the lungs to the AO. Blood flow into the RV, as seen with saline bubble contrast, occurred during the relaxation phase. Measurements of the heart made from the parasternal long-axis view showed: 1) no appreciable reduction in LV dimension during compression (average 2.8%, range 1.9-3.8%); 2) the reduction in LA and RV outflow tract dimension with chest compression averaged 22.8% and 52.7% respectively. Our study confirms that the flow of blood from the heart generated by chest compression during CPR is not caused by compression of the LV and supports the evidence that blood flow during CPR results from changes in intrathoracic pressure. Blood flow from direct compression of the LA and AO may be a factor in some patients.

THE PLACEBO RESPONSE IN VASOTONIC ANGINA-A CRITICAL FACTOR IN DRUG TRIAL DESIGN.
Rose M. Robertson, MD, FACC; Yvonne Bernard, RN; David Robertson, MD, Vanderbilt Medical Center, Nashville TN.

Many agents have been thought efficacious in vasotonic angina(VA) because a decrease in ischemic episodes followed their administration. We analyzed more than 1500 episodes of VA in 10 patients(pts) (ages 38-72;6 female,4 male) admitted to hospital for diagnosis and therapeutic trials. All pts had chronic recurrent episodes of myocardial ischemia which were not preceded by a rise in heart rate or intra-arterial pressure. Coronary anatomy ranged from angiographically normal (1 pt) to 90% stenosed (1 pt), with 7 pts having 30-50% narrowings. We performed all trials in a random-order, double-blind, placebo(PLA)-controlled fashion, with continuous ECG recordings throughout. An initial PLA run-in period of 2-4 days was followed by multiple cross-overs back to PLA between trials of therapeutic agents. We tabulated the frequency of ischemic episodes on initial PLA days and during days of later PLA periods more than 5 half-lives removed from active agents. Two patterns emerged. Two pts had stable VA, with 12-37 episodes of ischemia/day, unchanging over 6 weeks of observation. All other pts had a gradual decrease in the frequency of episodes, often mimicking a therapeutic response. In 6 of 8, the decrease on PLA day 2 ranged fro 20-100%. By the third PLA period, 4 pts had complete remission of episodes. Seven of the 8 pts had no more than 2 episodes/day by the fourth PLA period. The mean decrease in the daily number of ischemic episodes over the total hospital stay was 91% for these 8 pts, from a mean of 15/day to a mean of 2/day, ($p < 0.05$). We conclude that complete or near-complete remissions are characteristic of vasotonic angina. An inherent decrease in the frequency of ischemic episodes may easily confound the interpretation of therapeutic trials.

A COMPARISON OF VERAPAMIL AND NIFEDIPINE IN PATIENTS WITH PRINZMETAL'S VARIANT ANGINA PECTORIS.
SM Johnson, MD, DR Mauritson, MD, JT Willerson, MD, FACC, LD Hillis, MD, FACC, U of Texas Health Science Center, Dallas, TX.

The present study was performed to assess the relative efficacies of verapamil (V), nifedipine (N), and placebo (P) in the therapy of patients (pts) with variant angina pectoris (VAP). In 10 pts (6 men, 4 women, mean age 52 yrs) with VAP, V (400 ± 80 mg/day, mean$\pm$SD),N (82 ± 31 mg/day) and P each were administered for 2 months. Eight of the 10 pts were maintained throughout the 6 months of study on a stable dose of isosorbide dinitrate (138 ± 56 mg/day). Prior to study, all had cardiac catheterization: 8/10 had no fixed coronary artery disease (CAD), 1 had 1 vessel CAD, and 1 had 3 vessel CAD. Two of the 10 had been resuscitated from sudden cardiac death prior to study. During each 2-month period, the following were quantitated: (1)chest pains/week (wk), (2)nitroglycerin used/wk, and (3)required hospitalizations (HOS) for clinical instability. With both V and N, the number of chest pains/wk and the number of NTG used/wk were less than with P. During P, 4 pts required a total of 5 HOS for clinical instability; during N, 2 pts required such, whereas no pts required HOS during V.

	chest pains/wk	NTG/wk	HOS/2 months
P	15.9 ± 37.2	18.2 ± 44.0	5
V	2.2 ± 3.2*	3.2 ± 5.3*	0*
N	1.2 ± 1.5*	2.3 ± 4.1*	2

(*$p < 0.05$ when compared to P) V caused mild constipation in 2/10 pts not requiring a change of dosage; in contrast, N induced orthostatic dizziness in 3/10, substantial headache in 2/10, and pedal edema in 1/10, all necessitating a reduction in dosage. Thus, (1)verapamil and nifedipine demonstrate similar efficacy in the treatment of variant angina, although (2)in this small number of patients, nifedipine was associated with more substantial side effects than either placebo or verapamil.

VERAPAMIL IN THE TREATMENT OF PRINZMETAL'S VARIANT ANGINA: A LONG-TERM, DOUBLE-BLIND, RANDOMIZED TRIAL. SM Johnson, MD, DR Mauritson, MD, LD Hillis, MD, FACC, JT Willerson, MD, FACC, U of Texas Health Science Center, Dallas, TX.
This study was performed to assess the efficacy of verapamil (V) in patients (pts) with variant angina pectoris (VAP). In 13 pts (8 men, 5 women, mean age 52 yrs) with VAP, V (388±76 mg/day, mean±SD) was compared to placebo (P) in a double-blind, randomized, double-crossover trial of 9 months duration: 1 month of open-label V followed by four 2-month periods of blinded therapy (V-P-V-P or P-V-P-V). Ten of 13 pts were maintained on stable doses of isosorbide dinitrate (128±55 mg/day) throughout the study. During each 2-month period, the following were quantitated: (1)chest pains/week (wk), (2)nitroglycerin (NTG) used/wk, and (3)required hospitalizations (HOS) for clinical instability. During the 4 months of V, the number of chest pains/wk (2.0±3.5) and the number of NTG/wk (2.5±4.5) were less ($p<0.01$) than during P (12.1±27.8 pains/wk, 15.7±37.5 NTG/wk). None of 13 required HOS during V, but 4/13 required a total of 5 HOS during P ($p<0.05$). Of the 13 pts, 6 had clinical activity throughout the study, but the other 7 (54%) had prolonged periods of inactivity which, in 6/7, lasted the entire 8 months. In the 6 active pts, V had a marked salutary effect (3.8±3.1 pains/wk, 4.6±5.7 NTG/wk) when compared to P (24.7±36.2 pains/wk, 30.1±49.8 NTG/wk, $p<0.01$). V was well tolerated, causing only minor constipation not requiring a change of dosage. Thus, (1)many patients with variant angina have prolonged periods of clinical quiescence even without calcium antagonists, emphasizing the need for properly-designed studies of potential therapeutic agents; and (2)in a long-term, double-blind, randomized study, verapamil is safe and efficacious in the treatment of variant angina and is especially beneficial in those with clinically-active disease.

BENEFITS OF ADDED NIFEDIPINE IN UNSTABLE ANGINA PERSISTING DESPITE BETA BLOCKADE AND ISOSORBIDE DINITRATE
Frans Hagemeijer, MD, FACC, Sint Franciscus Gasthuis and Thoraxcenter, Erasmus University, Rotterdam, The Netherlands.

Unstable angina (UA) consisting of angina at rest associated with reversible ischemia on the ECG was treated with bed rest, oxygen, sedation (diazepam 5 mg tid), beta blockade to slow heart rate to <60/min (metoprolol 50-200 mg/day) and isosorbide dinitrate (5 mg every 2 hours). Despite therapy UA persisted in 45 patients (pts), 31 men and 14 women aged from 33 to 81 (mean: 61.6); 33 pts had a prior myocardial infarction (MI), 11 of them <10 days before the onset of UA. Nifedipine (60 mg/day) was added to the previous drugs. UA remained unstable in 8 pts but was stabilized during at least 1 month in 37 pts. The Table shows the 1-19 months (mean: 10) follow-up of these pts and occurrence of MI or coronary artery bypass surgery (CABS) according to the severity of residual angina: invalidating (I), serious (S), moderate (M) or absent (A) with medication:

	Persisting UA	Severity of stabilized UA				Total
		I	S	M	A	
Age >70	1	2	3	5	2	12
MI	1	1	0	0	0	1
Age <70	7	4	5	10	6	25
MI	3	0	0	1	0	1
CABS	4	4	5	1	0	10

Nifedipine caused transient headache in 7 pts, leading to cessation of the drug in 1 pt.

Nifedipine thus proved to be a valuable addition to conventional therapy for UA, suggesting that coronary artery spasm is an important contributing factor in this syndrome.

SATURABLE METABOLISM OF PERHEXILINE MALEATE: CORRELATIONS WITH LONG-TERM TOXICITY
John D. Horowitz, MB; Pamela M. Morris, BSc; Olaf Drummer, MSc; Alan J. Goble, MD; and William J. Louis, MD, Departments of Cardiology and Clinical Pharmacology, Austin Hospital, Heidelberg, Victoria, Australia.

Perhexiline maleate (Px) is a calcium channel antagonist which is an effective prophylactic anti-anginal agent, with minimal cardiovascular adverse effects. However, the chronic administration of Px may cause hepatitis or peripheral neuropathy, limiting the clinical usefulness of Px, which is cleared largely by hepatic hydroxylation. The current investigation examines the possibility of a pharmacokinetic basis for these adverse effects. Single-dose pharmacokinetic studies were performed in six patients with severe angina pectoris using oral Px doses of 150 and 300 mg. A sensitive (threshold 5 ng/ml) and specific high performance liquid chromatographic assay was used. Doubling of the Px dose was associated with a prolongation of mean elimination half-life (from 11.2±2.1 S.E.M. to 19.1 ±2.8 hours; $p<0.01$) and a disproportionate increase (mean 5.3-fold) in area under the plasma concentration-time curve suggesting saturable hepatic hydroxylation of Px. Steady-state studies in 17 patients treated with Px indicated a therapeutic plasma concentration range of approximately 150 to 600 ng/ml. Five cases of Px toxicity (2 of peripheral neuropathy, one each of hepatitis, blurred vision and nausea) were all associated with Px levels above 700 ng/ml (mean 1570±370 ng/ml), and were reversible with readjustment of Px dosage. We conclude that Px is a long-acting calcium channel antagonist which is prone to accumulate in some patients due to limited capacity for hepatic Px metabolism. Monitoring of plasma Px concentrations at regular intervals will permit optimization of long-term therapy with Px.

ANTIPLATELET EFFECTS OF VERAPAMIL IN MAN

Sergio Chierchia, MD; Filippo Crea, MD; Walter Bernini, Gianfranco Gensini, MD; Oberdan Parodi, MD; Raffaele De Caterina, MD; Attilio Maseri, MD; FACC, Istituto di Fisiologia del C.N.R. Pisa

We studied the "in vivo" and "in vitro" effects of verapamil (V) on human platelets. Platelet rich plasma was obtained by 20 healthy volunteers and Thrombin (T), Collagen (C), ADP and Adrenaline (A) induced platelet aggregation (Born) was assessed after a 20 min incubation with 3 increasing concentrations of V ($4x10^{-6}$, $4x10^{-5}$ and $4x10^{-4}$ M). A dose dependent decrease in "in vitro" platelet aggregation was observed, more pronounced for C and A.

V	ADP	T	C	A
$4x10^{-6}$ M	-8±6*	+17±12	-29±22*	-16±11*
$4x10^{-5}$ M	-31±10**	-15±23	-58±28**	-73±9**
$4x10^{-4}$ M	-52±10**	-51±15**	-97±2***	-100±0***

*$p<0.05$; **$p<0.01$; ***$p<0.001$

In 9 coronary patients with an abnormal platelet function, V was given i.v. for 30 min at a rate of 5μgr/Kg/min under continuous ECG and pressure (AP) monitoring. Platelet circulating aggregates (PCA), platelet cAMP and thromboxane B_2 (TxB_2, RIA) were measured during control, at 3, 15, 30 min of infusion and 30, 60, 90 min after. In all subjects V produced, within 3 min, a progressive decrease in PCA (55±7% $p<0.01$), associated with a drop in systolic AP (14±3% $p<0.01$) and with an increase in HR (11±2%, $p<0.05$). All these effects persisted up to the end of V infusion. AP and HR returned to the baseline within 90 min while PCA were still reduced, although not significantly. No changes in plateled cAMP and TxB_2 were noted. We conclude that V exerts both in vitro and in vivo remarkable antiplatelet effects, probably related to its slow-channels blocking properties. This additional pharmacological effect could be advantageous in the management of coronary patients.

CORONARY ARTERY DISEASE: SURGICAL CONSIDERATIONS
2:00-3:30

THE PROGRAM ON THE SURGICAL CONTROL OF THE HYPERLIPIDEMIAS (POSCH): A STATUS REPORT

Richard B. Moore, MD, FACC; Henry Buchwald, MD, FACC; Richard L. Varco, MD; John M. Long, EdD; John P. Matts, PhD; and the POSCH Group, University of Minnesota Medical School, Minneapolis, Minnesota.

The POSCH is a multicentered NHLBI-funded CHD secondary intervention clinical trial of the lipid-atherosclerosis hypothesis using partial ileal bypass surgery(PIB) to effect maximal plasma lipid reduction in subjects (30-64 yrs, free of diabetes, hypertension, obesity) with one documented myocardial infarction. Of the first 286 male subjects 149 were normo- and 137 were hyper-lipoproteinemic (53-IIA, 16-IIB, 68-IV). At baseline there were no significant differences in plasma total cholesterol (C), triglycerides (TG), or lipoprotein (VLDL, LDL, HDL)-cholesterol concentrations between 153 Control and 133 PIB subjects. Baseline values for PIB Group (mean± SD):

TYPE	n	C	TG	VLDL	LDL	HDL
N	70	242±14	164±47	23± 7	177±14	41.0±9.7
IIA	25	298±48	159±47	22± 8	237±47	42.5±9.4
IIB	7	303±22	275±65	54±19	216±13	40.0±11.3
IV	37	258±30	365±166	61±25	158±29	35.5±6.5

At 3 yrs Controls had a 11% reduction in HDL-C (36.7 vs 41.0 mg/dl, $p<.01$) but no significant changes in the other plasma lipids; the PIB Group had significant($p<.001$) reductions of 30% in C (181 vs 250 mg/dl) and 43% in LDL-C (106 vs 186 mf/dl) and a 1.1% increase (NS) in HDL-C. There was a 3.7 mg/dl difference in HDL-C between PIB and Control at 3 yrs ($p<.05$). PIB is lasting, safe, obligatory in its action, and highly effective resulting in a marked reduction in the major atherogenic lipoprotein (LDL) and a relative increase in the "protective" lipoprotein (HDL).

CORONARY BYPASS VS MEDICINE: PROBLEMS AND GUIDELINES IN ASSESSING MORTALITY DIFFERENCES

Frank E. Harrell, Jr., Ph.D., Kerry L. Lee, Ph.D., David B. Pryor, M.D., Robert A. Rosati, M.D., Duke University Medical Center, Durham, North Carolina

Assessing the effect on survival of coronary bypass surgery(S), especially in series where the treatment is not randomly assigned, is complicated by early medical (M) deaths and treatment selection bias. Some reports exclude early M deaths from analysis, but differing definitions of "early" can alter the results. The approach used in adjusting for treatment selection also affects assessment of S.

Of 2630 consecutive patients(PTS) catheterized for chest pain at Duke University Medical Center having significant (≥75%)coronary stenosis, there were 1504 M and 1126 S PTS. One year survival for all M PTS was .913. S PTS to be counted as such had to survive from catheterization to operation. Crediting to M this additional survival time (median, 3 weeks)improves the estimate to .926. In 209 PTS with significant left main disease (87 M, 132 S, median time to operation 2 weeks), this adjustment improves one year M survival estimates from .676 to .733. Statistical methods exist to adjust for baseline factors and analyze the S effect treating every S PT as an M PT until surgery.

Compensating for treatment selection bias by adjusting for baseline prognostic factors is a major problem. Experimenters frequently adjust only for factors imbalanced between treatment groups. Depending on the meaning of "balance", this method can lead to varying conclusions. For example, suppose 7 M PTS had ejection fraction(EF) of .1,.2,.3,.4,.5,.6,.7 and 3 S PTS had EF of .3,.4,.5. Statistical tests indicate no differences in average EF. If only the M PTS with EF<.3 died, S would appear to have an effect; adjusting for EF removes the effect. One should adjust for factors even weakly related to survival in either M or S.

CURRENT RISK SURROUNDING CORONARY BYPASS SURGERY

D. Craig Miller, MD, FACC; Edward B. Stinson, MD, FACC; Philip E. Oyer, MD; Bruce A. Reitz, MD; Stuart W. Jamieson, MB, BS; Norman E. Shumway, MD, FACC; Stanford University School of Medicine, Stanford, California.

Contemporary reassessment of the changing operative risks associated with coronary artery bypass(CABG) surgery is useful to facilitate clinical decision-making and comparative analysis. Two groups of consecutive patients(PT) undergoing isolated CABG were compared: Group A(1971-75, n=1,000) and Group B(1979,n=437). The latter group was older and had more advanced disease and LV dysfunction as evidenced by the following preoperative variables(A vs B): age-54 vs 59 yr*; CHF-20% vs 26%***; NYHA IV=18% vs 33%*; unstable angina-27% vs 55%*; carotid disease-2% vs 5%**; LV dyskinesis-4% vs 7%***; LVEDP-11.6 ± 0.3(± SEM) vs 15.1 ± 0.4 torr*; ejection fraction-61 ± 1% vs 56 ± 1%**; number of vessels diseased-2.7 ± 0.04 vs 3.2 ± 0.06*. Although fewer CABG/PT(2.4 ± 0.03 vs 2.9 ± 0.04*) were performed and adjunctive endarterectomy was carried out less frequently(9% vs 16%**) in Group A, average ischemic time(55 ± 0.7 vs 52 ± 0.8 min**) and CPB time (109 ± 1 vs 93 ± 1 min*) were significantly longer. More importantly, the incidence of perioperative myocardial infarction declined from 8.7% in Group A to 2.7% in Group B($p < 0.0005$) and the operative mortality rate fell from 2.4% to 0.7%($p=0.017$). Patient selection was clearly not responsible for these improved results. These contemporary risks should be considered in the clinical decision-making process instead of results obtained during the earlier phases of the evolution of coronary surgery.

THE POTENTIAL ROLE OF INTRAVENOUS ANGIOGRAPHY IN MANAGEMENT OF CARDIAC SURGERY PATIENTS

W.D. Turnipseed, MD; P. D. Myerowitz, MD; A.B. Crummy,MD; C. Strother, MD; J. Sackett, MD; C. Mistretta, PhD; C. Shaw, D. Ergun; University of Wisconsin Hospitals, Madison, Wisconsin

Although arteriography is essential for precise definition of surgically correctable lesions it is of limited value as a method of diagnostic screening and postop assessment in coronary artery and peripheral vascular patients. Recent developments in computerized image enhancement make it possible to visualize coronary artery grafts and peripheral vascular system by intravenous injection of iodinated contrast media, and promises to expand the traditional role of arteriography without many of the dangers of direct arterial catherization. The technique is performed by power injecting 40-60 cc of contrast media through a #16 angiocath into an arm vein. After injecting contrast media, a mask image is taken followed by either a sequence of 6-10 static images taken at 1.5 second intervals or a continuous fluoroscopic sequence. A digital video processor subtracts images from the mask producing contrast enhanced arterial images that can be converted to hard copy arteriography by multiformat camera or stored on video tape. Intravenous angiography can accurately identify plaquing, stenosis, occlusion and aneurysmal changes in arteries peripheral to the heart and distinguish occlusion from patency in coroary bypass grafts. The ability to easily obtain accurate anatomical detail of the carotid and extremity vessels may allow more precise definition of preoperative risk factors in candidates for elective coronary artery bypass and provides an excellent means for determining graft patency after coronary artery bypass surgery. Postoperative ventriculography can also be performed by this method.

EVALUATION OF AORTOCORONARY BYPASS GRAFT PATENCY STATUS BY COMPUTED TOMOGRAPHY

Frederic R. Kahl, M.D., FACC; Neil T. Wolfman, M.D.; L. Earl Watts, M.D., FACC, Bowman Gray School of Medicine, Winston-Salem, NC

The efficacy of contrast enhanced computed tomography (CT) to define graft patency status was studied in 42 patients with 100 aortocoronary bypass grafts. The status of each graft had been determined earlier by angiography. A rotary fan beam whole body scanner with a 2 second scan duration was used. Initial scans determined the optimal level for study of the graft; patency was assessed by CT enhancement of the graft after bolus intravenous injection of 30 ml meglumine and sodium diatrizoate. The CT studies were evaluated without knowledge of the angiographic findings; graft status by CT was interpreted as either patent, occluded, or equivocal.

Overall, CT correctly defined graft patency status in 79/100 grafts, incorrectly defined graft status in 9/100 grafts, and, in 12/100 grafts, the CT diagnosis was equivocal. CT correctly identified 61/74 patent grafts and 18/26 occluded grafts. Patency status was correctly defined by CT in 35/37 grafts to the left anterior descending coronary artery, in 23/30 grafts to the circumflex branches, and in 19/31 grafts to the right coronary artery.

These data indicate that CT is a promising non-invasive method of determining patency of aortocoronary bypass grafts, especially in grafts to the left anterior descending coronary artery.

CHANGES IN LATE CORONARY ARTERY BYPASS GRAFTS: THE VARIABILITY OF THEIR INTIMAL ATHEROSCLEROSIS.

Bernadine H. Bulkley, M.D., F.A.C.C., The Johns Hopkins School of Medicine and Hospital, Baltimore, Maryland.

Long-term success of coronary artery bypass surgery will, in large part, be determined by the fate of the implanted vein graft. Early intimal changes have been described, but little is yet known about grafts implanted for months to years. In this study, 48 grafts implanted in 24 autopsied patients from 1 month to 9 years (average 260 months) were evaluated by postmortem angiography, gross and histologic examination, and findings correlated with anastomosis patency and implantation period. Of the 24 patients, 83% had at least one patent graft. The lumen of 15 of the 48 grafts (31%) were narrowed by > 50% by an intimal fibrous lesion histologically identical to atherosclerosis; in one graft implanted for 9 years, a complicated atheroma had formed with necrotic debris and extracellular lipid. The development of graft atherosclerosis varied within patients, and from patient to patient, with only limited relationship to duration of implantation: 7 of 15 (47%) narrowings of grafts in excess of 50% of their lumen were in grafts implanted for over 2 years (average 4.6), but the remaining 8 focal graft narrowings developed in ones implanted from 2 to 8 months. In 9 grafts severe intimal lesions were associated with stenosis or occlusion at the coronary anastomosis site.

Thus, although period of implantation is one variable in graft atherosclerosis, other factors including the hemodynamics of the graft appear as important and needs further clinical and pathologic study.

DIVERSE ASPECTS OF CARDIOMYOPATHY
2:00-3:30

USEFULNESS OF SEPTAL ENDOMYOCARDIAL BIOPSY FOR EARLY DIAGNOSIS OF CHAGASIC CARDIOMYOPATHY.

Hugo A. Carrasco G. MD; Ernesto Palacios, MD; Cecilia Scorza, MD; Antonio Rangel, MD; George Inglessis MD; FACC; Abdel Fuenmayor, MD. Universidad de Los Andes. Mérida. VENEZUELA.-

There is no current world medical information about myocardial biopsy studies in Chagas'disease. We present the ultrastructural, histopathologic and inmunologic findings from 180 septal endomyocardial biopsies taken in 60 chagasic patients via percutaneous jugular approach. No complications were observed. All studies were interpreted following a specially designed cytogram; patients were classified into four evolutive groups: IA: no cardiac disease. IB: early myocardial damage by left cine-ventriculogram only; II: advanced myocardial damage with abnormal EKG and left cine-ventriculogram, and III: clinical congestive heart failure. Sixty percent of group IA patients had evident degenerative changes, decreased mitochondrial and miosine ATPase activity and increased mono amino-oxidase (MAO) activity indicative of myocardial damage. Ninety percent of group IB patients had similar, although more advanced changes, with added increased lysosomal activity. Almost everyone patient of groups II and III (95 and 100%) had severe ultrastructural and histochemical abnormalities with increased incidence of lipids and glycogen deposits, cellular infiltrates and fibrosis. The myocardial biopsy is the most sensitive method currently available for diagnosis of early myocardial damage in Chagas' disease, since it could detect evident abnormalities in 60% of otherwise "normal" chagasic patients. It could also be useful for following the evolution of myocardial lesions, for evaluating therapeutic effects and for studying of its patho - genetic mechanisms.

RADIONUCLIDE ANGIOGRAPHY AND ENDOMYOCARDIAL BIOPSY IN THE ASSESSMENT OF DOXORUBICIN CARDIOTOXICITY.

Maurice Druck, MD, Ben-Zion Bar-Shlomo,MD, Karen Gulenchyn,MD, David Hilton,MD, George Jablonsky,MD, Avrum Gotlieb,MD, Malcolm Silver,MD, Patricia McEwan,MD, David Feiglin,MD, John Morch,MD, Wm. Evans,MD, Peter McLaughlin,MD,FACC, Toronto General Hospital, Toronto, Ontario Canada.

We studied 33 patients (Pts) with a mean age of 53 yrs (20-75 yrs), who were receiving doxorubicin (D) for malignant disease, to determine the relationship between functional and morphological changes in the myocardium at different dose levels of D, Serial Pt evaluations included physical examination, chest x-ray, ECG, endomyocardial biopsy (EMB), and rest and exercise gated nuclear angiograms (GNA) at doses of D ranging from 1440954mg/m^2 (mean 452mg/m^2). Abnormalities of physical examination, chest x-ray and ECG were insensitive predictors of D cardiotoxicity. Correlation of GNA and EMB on 27 Pt evaluations are presented:

		GNA	
		NORMAL (N)	ABNORMAL (ABN)
EMB	NORMAL	0	0
	ABNORMAL	9	18***

N=27

*Included are 5 Pts with normal rest GNA but abnormal exercise response. **All Pts with resting EF 45% had significant abnormalities of EMB.

We conclude:

1. The good correlation between GNA and EMB in detecting early D cardiotoxicity allows GNA to be reliably used in management of D therapy.
2. An exercise study should be performed when rest EF is N, but is unnecessary when rest EF is ABN.
3. All Pts with resting EF 45%, exclusive of other cardiac disease should have D discontinued.
4. Biopsy is useful in assessing D cardiotoxicity in patients with other possible causes of ABN. GNA.

RIGHT VENTRICULAR CARDIOMYOPATHY PRESENTING WITH RECURRENT VENTRICULAR TACHYCARDIA

D.H. FITCHETT, MB; C.G. MacArthur, MB; C.M. Oakley, MD, FACC; D.M. Krikler, MD, FACC; J.F. Goodwin, MD, FACC, Royal Postgraduate Medical School, Hammersmith Hospital, London, England.

Dilated cardiomyopathy usually presents with either left or biventricular failure, less often with arrhythmia or embolism. We describe 14 patients with severe right ventricular dilatation in whom there was apparent sparing of the left ventricle. Eight patients were male and six female, age range six to 55 years, average 28. Ventricular tachycardia was the cause of referral in seven patients, none of whom had other symptoms or signs of cardiac abnormality. Only five patients had clinical heart failure. The ECG suggested right ventricular abnormality in 12 patients and two had sino atrial disease. Echocardiography revealed marked dilatation of the right ventricle with a normal left ventricle and right ventricular angiography showed marked dilatation but only two patients showed any detectable abnormality of left ventricular function. Ventricular arrhythmias were documented in eight patients with appearances suggesting an origin in the right ventricle confirmed by electrophysiological studies in three. Six patients died, three suddenly and three with severe heart failure. Autopsy in three patients showed extreme dilatation of the right heart chambers and normal appearance of the left heart chambers although histological abnormality was found in both ventricles. It is suggested that the spectrum of dilated cardiomyopathy includes apparently isolated right ventricular dysfunction and should be suspected particularly when ventricular tachycardia is associated with T wave inversion in right-sided ECG leads.

MORPHOLOGIC BASIS FOR ELECTROCARDIOGRAPHIC EVIDENCE OF CONDUCTION SYSTEM INVOLVEMENT IN DUCHENNE'S MUSCULAR DYSTROPHY (DMD)

Shyamal K. Sanyal, F.A.C.C., Warren W. Johnson, M.D., Saroja Bharati, M.D., and Maurice Lev, M.D. St. Jude Children's Research Hospital, Memphis, Tennessee and Hecton Institute, Chicago, Illinois.

Twelve-lead electrocardiograms were analyzed in 50 boys, 5 to 18 years of age, who had clinical, biochemical and muscle biopsy evidence of DMD. Cardiac conduction system abnormalities were noted in 27 patients (54%). Intra-atrial conduction abnormalities were most common and included: abnormal PV_1 index in 14 patients, a short P-R interval in 11 and coronary sinus rhythm in 2. Intraventricular conduction abnormalities were noted in 5 patients: right bundle branch block in 2, left anterior hemiblock in 2 and bifascicular block in 1. First-degreee atrioventricular block was seen in 1 patient. Seven patients had more than one type of conduction defect. Serial follow-up observations disclosed that the conduction abnormalities were progressive.

To determine the genesis of these EKG abnormalities, we studied systematically, the morphology of the cardiac conduction system in 4 patients with DMD. In each instance, within 1-2 hours of death, hearts were perfused at 4°C for four hours either with 2.5 glutaraldehyde (2 hearts) or with 10% formalin (2 hearts). In contrast to the heart of sex-matched, normal control subject, each DMD heart showed multifocal areas of degenerative changes characterized by vacuolization, fatty infiltration, and nuclear pyknosis. Other changes included variation in size and staining of myofibers, splitting and loss of myofibers and moderate-to-severe fibrosis. These dystrophic changes at the cellular level were similar in each patient and involved, with varying degrees of severeity, sino-atrial node, atrial preferential pathways, atrioventricular node, bundle of His and subendocardial as well as intraventricular right and left bundle branches.

Our observations indicate a high prevalence of cardiac conduction abnormalities in patients with DMD. Morphologic observations establish that the EKG abnormalities result from dystrophic involvement of the cardiac conduction system in these patients.

CARDIAC EFFECTS OF PLASMA FROM PATIENTS WITH GRAVES' DISEASE

Anthony Nathan,MB;Paresh Dandona,DPhil;Donald Longmore,MB. St.Bartholomew's Hospital,London,England

Patients(pts) with cardiomyopathies(CM) have a higher than expected incidence of thyrotoxicosis.CM may occur during a euthyroid phase.The possibility that plasma rich in thyroid stimulating immunoglobulins(TSI) may have a role in the pathogenesis of such CM has been investigated as TSI are recognised to have extrathyroidal effects. Plasma from 3 patients(A,B,and C) with Graves' disease, and from controls,were tested on intact fetal mouse hearts in organ culture.Each of the pts had become euthyroid but all had fulminant exophthalmos.TSI levels were elevated in pts plasma,but not in the controls.Electrolytes and thyroid hormone levels were normal in all the pts and controls.Test plasma was added to aliquots of tissue culture medium.40 hearts were used in each experiment,20 for the pts plasma,and 20 for the controls.Plasma from each of the 3 pts caused a significant increase in mean heart rate in comparison with controls(A:131,control: 83;$p<0.001$, B:212,control:109;$p<0.001$, C:181,control:97; $p<0.01$).Survival in hearts incubated with pts plasma was significantly reduced in comparison with control(50% survival:pts-15.5 days,control-27 days).In addition,plasma from patient A obtained after 4 days of therapeutic plasmaphoresis(when TSI levels were significantly reduced) had no effect on either heart rate or survival when compared with controls.

These results suggest that a plasma factor present in these patients exerts a deleterious effect on cardiac tissue causing initial stimulation(with an increase in heart rate) followed by premature death.These effects may be caused by TSI,which interestingly often persist for years after a euthyroid state has been achieved.

REDUCTION OF MYOCARDIAL FIBROSIS BY EARLY METHYL PREDNISONE OR IBUPROFEN ADMINISTRATION IN EXPERIMENTAL RADIATION INDUCED HEART DISEASE

William C. Reeves, MD, FACC; David Cunningham, MD; Joseph Schwiter MD; Arthur Abt, MD; Sonia Skarlatos; Mary Ann Wood; Larry Whitesell

The ability of methyl prednisone (MP) and ibuprofen (IB) to reduce the severity of the late stage of radiation-induced heart disease (RIHD) was assessed in 57 New Zealand white rabbits. Thirteen rabbits served as unirradiated controls. (Group C) Fifteen rabbits in group A (MP) and 15 rabbits in group B (IB) received intravenous drugs before and shortly after cardiac irradiation. No drug was administered to 14 irradiated rabbits in the final group. All 15 rabbits in group A lived for 100 days. Thirteen of the 15 rabbits in group B lived for 100 days. Only 7 of the 14 rabbits in the untreated irradiated group lived for 100 days. Longevity was significantly improved in groups A ($p<.01$) and B ($p<.05$) when compared to the untreated irradiated group. Surviving animals were sacrificed at 100 days post irradiation. Myocardial fibrosis was evident in all irradiated groups by microscopic examination. Quantitation of the fibrosis was achieved by determination of myocardial hydroxproline content (MHP) in 13 untreated irradiated rabbits and in 13 rabbits each in groups A, B, and C. MHP was significantly increased in the untreated irradiated group (72.0 ± 5.3 mg/gram dry tissue) (Mean $\pm$ SEM) compared with group C (34.4 ± 2.2) ($p<.01$). MHP was significantly reduced in groups A (48.7 ± 6.2) ($p<.05$) and B (49.1 ± 7.1) ($p<.01$) when compared to the untreated irradiated group. Early MP or IB administration retards the development of myocardial fibrosis and improves survival in this experimental model of RIHD.

ECHOCARDIOGRAPHY: MYOCARDIAL ISCHEMIA & INFARCTION
2:00-3:30

QUANTITATIVE REGIONAL MYOCARDIAL PERFUSION SCANNING WITH CONTRACT ECHOCARDIOGRAPHY

William J. Bommer, MD, FACC; Julia Rasor, MS; Glenn Tickner, MS; Patricia Takeda, MD; Larry Miller, PhD; Garrett Lee, MD; Dean T. Mason, MD, FACC; Anthony N. DeMaria, MD, FACC, University of California, Davis and Sunnyvale, California

Current echocardiography techniques provide no quantitative information about myocardial perfusion. Thus we developed a new method for quantitating myocardial perfusion in the presence of coronary artery obstruction. During two-dimensional echocardiographic imaging, we injected a suspension of stabilized microbubbles (10-30 μ) into the left ventricle (LV) and coronary arteries (COR) of 7 dogs before and after obstruction of the left anterior descending branch (LAD). Using echo-videodensitometry, perfusion in selected areas of myocardium could be monitored by recording contrast curves and measuring both peak contrast effect and the time to 50% disappearance of peak effect (DT-50). In normal COR, selective left coronary injections produced uniformly bright opacification of the entire myocardial circumference. After LAD obstruction, septal myocardial opacification was significantly reduced (mean reduction of peak contrast effect 90%) compared to the LV free wall. Normal COR perfusion curves showed a significantly prolonged DT-50 (10.5 sec), when compared with LV chamber curves (DT-50 = 3 sec, $p<.01$). Although the peak contrast effect in ischemic tissue was reduced, DT-50 of ischemic areas was unexpectedly shorter than normal (7 versus 10.5 sec, $p<.05$). Thus, echo-videodensitometry of contrast myocardial perfusion scans yields quantitative curves which differentiated normal from ischemic muscle. The accelerated DT-50 seen in association with decreased peak contrast effect in ischemic muscle may reflect a reduced microbubble to vessel diameter ratio as well as reduced flow.

TWO-DIMENSIONAL ECHOCARDIOGRAPHIC ASSESSMENT OF WALL THINNING AND ITS RELATION TO PERFUSION DURING GRADED CORONARY STENOSIS.

Natesa Pandian, MD; Richard Kerber, MD, FACC, CV Cent, Univ of Iowa Hosp, Iowa City, Iowa.

The utility of two-dimensional echocardiography (2DE) in detecting myocardial ischemia with varying degrees of coronary stenosis (CS) without complete occlusion is not established, and the change in perfusion accompanying 2DE wall thinning in CS has not been defined. To study this, we created circumflex CS in 25 dogs. Coronary blood flow (CBF) was measured by electromagnetic flow probes and myocardial perfusion (P) by radioactive microspheres. 70% CS abolished reactive hyperemia; 90% CS reduced CBF by half. To induce ischemia, isoproterenol (Iso) and acute aortic constriction (AC) were added to CS. Ischemia was defined as systolic wall thinning by ultrasonic sonomicrometers and by 2DE. From 2DE short-axis left ventricular images, the % systolic thickening of 12 equidistant wall radii was analyzed. Control wall thickening was 34±SD11% (range 5 to 100%). Systolic thinning was never seen with 2DE or sonomicrometers in control state or with 70% or 90% CS alone, nor was P significantly reduced with CS alone. When Iso and AC were superimposed on 90% CS, segmental thinning occurred in all dogs, with thinning of individual radii ranging from -5 to -53%. In the radii opposite the ischemic segments, thickening increased from 33±12% control to 81±39% ($p<.01$). Whenever thinning was detected severe hypoperfusion was inevitably present, with P falling from 116±29 ml/100g/min control to 28±16 ml/100g/min during thinning ($p<.01$). Conclusion: Even severe CS may not cause decreased P at rest, and 2DE in this case shows no wall thinning. Interventions which cause hypoperfusion produce ischemia and wall thinning in the involved area, and exaggerate thickening in the opposite nonischemic myocardium. This permits 2DE detection of severe CS; systolic thinning always signified perfusion <25% of control.

HIGH FREQUENCY EPICARDIAL ECHO MAPPING OF SEGMENTAL MYOCARDIAL PERFORMANCE AT MULTIPLE SITES ON RIGHT AND LEFT VENTRICLES

Mariell Likoff, Nathaniel Reichek, John Macoviak, Alden Harken, FACC, Martin St. John Sutton, Ali Muhammed, Ted Plappert and John A. Kastor, University of Pennsylvania, Philadelphia, PA.

To develop a new method for analysis of segmental myocardial function, 7.5 mHz transducers (resolution 0.2mm) were used to record epicardial echograms at multiple sites on both ventricles in 7 open-chest dogs before, during and after ischemia produced by brief coronary occlusions; and in 6 men with 2 or 3 vessel coronary disease during coronary surgery. Plots of myocardial thickness(T) and its normalized derivative dT/dtT (an analogue of velocity of fiber shortening) were compared to strain gauge recordings in dogs. Dog left and right ventricular normal peak systolic(PS, 7.3±1.8 vs 6.8±2.3) and diastolic(PD, -6.0±1.4 vs -6.6±3.2) dT/dtT were similar and occurred early in systole and diastole, respectively. Ischemia led to prompt fall and delay in PS and PD dT/dtT (-3.0T/sec, $p<.001$; +1.4, $p<.02$; n=17) with paradoxical systolic thinning in central ischemic zones. Echograms were more sensitive to ischemia than strain gauge, but as specific. Reperfusion promptly corrected PD dT/dtT but PS dT/dtT improved slowly and incompletely. Pre-bypass recordings in man demonstrated marked heterogeneity of myocardial function even in areas without transmural infarction or ventriculographic abnormality. The echo method is simple, rapid, atraumatic, has excellent spatial resolution and permits more extensive mapping than strain gauge. We conclude that epicardial echo mapping can improve analysis of segmental myocardial function and is readily applicable to man.

CROSS-SECTIONAL ULTRASONIC IMAGING OF THE CORONARY ARTERIES (CA's) IN OPEN CHESTED HUMANS; THE EVALUATION OF CORONARY ATHERSCLEROTIC LESIONS (ACL) AT SURGERY.

David J.Sahn, MD, FACC; Brian Barratt-Boyes, MD, Ken Graham, MD, Alan Kerr, MD, Trevor Agnew, MD, Antony Roche, MD, Peter Brandt, MB, ChB, Univ. of Ariz. Health Sci. Ctr., Tucson and Cardiosurgical Unit, Green Lane Hosp., Auckland, N.Z.

Because the location of angiographically demonstrated ACL at surgery is inexact, we have developed a new ultrasonic method for imaging CA's in open chested humans during surgery. A 9mHz electronically focussed water path ultrasound scanner was used to image the CA's on three anaesthetised open chested sheep. The images were compared to anatomic observations and measurements. CA's and coronary veins could be identified in longitudinal as well as transverse sections. In 10 human subjects, the ultrasound probe was gas sterilised and placed directly on the beating heart. The right (R)CA orifice was imaged by placing the probe over the aorta and the RCA could be followed in the atrioventricular sulcus. The left (L)CA orifice was imaged through the pulmonary artery and the main LCA, the proximal L circumflex and L anterior descending could be imaged. The distal L anterior descending CA was imaged on the anterior surface of the heart in the inter-ventricular sulcus. These vessels could be studied with the heart beating or during cardiopulmonary bypass. The distal L circumflex could be imaged only on bypass with the heart rotated apex up. Using this method compared to angiography and surgical observations, we have imaged normal CA's as well as ACL in the proximal R, mid-R, proximal L main and L anterior descending CA's; in two cases confirming the presence or absence of additional occlusive ACL's in CA's poorly filled angiographically. This new method allows the intra-operative verification and localisation of ACL and aids in the accurate placement of saphenous vein bypass grafts.

DISCRETE INTRAMURAL SONOLUCENCY: A NEW ECHOCARDIOGRAPHIC FINDING IN ACUTE MYOCARDIAL INFARCTION.
J.A. Werner, M.D., FACC, S.M. Speck, M.D., H.L. Greene, M.D., FACC, C.L. Janko, B.W. Gross, M.D. Harborview Medical Center, University of Washington, Seattle, Washington.
Pathological studies have suggested evolutionary changes within myocardium during acute myocardial infarction (AMI) including edema, hemmorhage and geometrical changes occurring over hours to days. To determine if such changes may be detected non-invasively early in the clinical course, we performed two-dimensional echocardiography (2DE) within 24 hours of admission on 27 pts with documented AMI by cardiac enzymes and EKG. Discrete areas of intramural sonolucency (DIS) were seen on 2DE corresponding to the EKG area of infarction in 10/27 (37%) pts - all with involvement of the anterior wall.

Follow-up studies at 48 hours, available in 5 pts, continued to show the abnormality in 4/5 pts and was equivocal in one. Six of the 10 pts with DIS died in hospital compared to 2/17 pts without DIS ($p<.03$). Autopsy performed in 3/6 fatal cases with DIS demonstrated myocardial rupture in 2/3 and extensive infarction with edema and hemmorhage in the remaining pt - all corresponding to the abnormal area (DIS) identified on the 2DE. Cardiac enzymes were markedly elevated in all pts and did not distinguish pts with DIS or subsequent death. We conclude that DIS represents edema and hemmorhage in the zone of acute infarction and when identified echocardiographically, suggests a poor clinical outcome.

CROSS-SECTIONAL ECHOCARDIOGRAPHY IN THE EARLY DETECTION OF ACUTE MYOCARDIAL ISCHAEMIA AND INFARCTION.
K. Daly, M.R.C.P.I., M. Monaghan, MSc, G. Jackson, M.R.C.P Cardiac Department, King's College Hospital, London, U.K.

Fifty patients (pts) with suspected diagnosis of acute myocardial infarction (M.I.) had cross-sectional echocardiographic studies carried out on admission to the coronary care unit and forty eight hours later. None had a past history of M.I. or hypertension. The LV wall was divided into 11 segments, and segmental wall motion defined as normal, hypokinetic, akinetic or dyskinetic. The degree of asynergy calculated was expressed as a percentage (normal 0% total dysynergy 100%) and compared with creatine phosphokinase (CPK) level and 12 lead ECG at the time of study.
M.I. was later confirmed in 40 pts on the basis of elevated CPK and/or ECG. Elevated percentage asynergy was present in 39 on admission, and in the remaining one at 48 hrs. M.I. could not be diagnosed in 17 of these on admission - 8 pts had normal CPK (134-26 i.u./L) rising to 1012 i.u./L at 48 hours, and 9 pts had non-diagnostic ECG patterns. All had evidence of L.V. wall motion abnormality (% asynergy score 23 on admission rising to 33 at 48 hours) 10 pts did not suffer M.I. 8 had normal echocardiograms. The remaining 2, whose ECGs showed acute ischaemic patterns had LV asynergy (% score 15) on admission- the echocardiograms reverted to normal after the acute ischaemic episode.
These findings indicate that cross-sectional echocardiography is a sensitive method of early detection of acute myocardial ischaemia and infarction in pts who have not had prior M.I. It is particularly of value when initial CPK values and ECG patterns are not diagnostic.

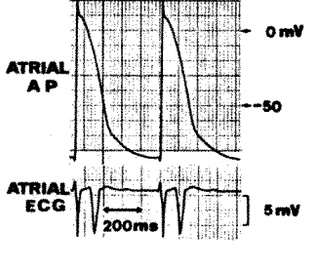
THE SINUS NODE AND ATRIUM
2:00-3:30

EFFECT OF OVERDRIVE PACING ON ELECTRICALLY AND NEUROLOGICALLY ISOLATED SINUS NODE IN OTHERWISE INTACT DOGS
Florence Chan MD, Jerry Gliklich MD, Brian Hoffman MD,FACC Columbia University, New York, N.Y.

Sinus node (SN) function is evaluated by atrial overdrive (OD) and atrial premature stimulation. Interpretation is difficult because SN activity is not directly recorded and reflex effects make unknown contributions to observed changes in atrial rhythm and rate. We have prepared isolated sinus nodes (sinus node islands SNI) in chronically instrumented dogs by a circumferential incision as described by Sealy. Electrodes were attached to the epicardium to record the SN electrograms. Pacing electrodes were attached to the atrial remnants. Isolation of the SNI from the atrium was demonstrated by the independence of the sinus and atrial rhythm and the ability to pace the SNI and atrium independently. Neurologic isolation of the SNI during the first 2 weeks was shown by a constant sinus rate during cervical vagal stimulation. Effects of OD and premature stimulation were compared for SNI and intact hearts. The SN electrogram permitted identification of SN capture during OD. In intact hearts OD at cycle lengths (CL) 800-400 msec caused marked prolongation of the return cycles. A progressive decrease in return CL was noted at pacing CL of 400-250 msec. Finally, at quite short CL, post-OD acceleration was seen. In the SNI, increasing OD suppression was again demonstrated at 600-300 msec CL. At CL of 300-180 msec, the extent of OD suppression decreased as the pacing rate increased. Post-OD acceleration was not seen.
We concluded that the SNI offered a good method of studying the response of SN to OD in the absence of reflex effects. The varying degree of suppression in response to different rates of stimulation is unrelated to neurotransmitter effects.

A NEW METHOD OF RECORDING TRANSMEMBRANE ACTION POTENTIAL FROM ATRIA OF IN SITU HEART
Toshio Akiyama, MD, FACC; Winshih Chang; Jay Luft, University of Rochester Medical Center, Rochester, NY

Cardiac motion interferes with in situ action potential (AP) recordings. We have recently developed a motion compensated micropipette holder (MCMH) which senses cardiac motion and lifts and lowers a micropipette of Ling-Gerard type and supporting apparatus in synchrony with heart beat. The MCMH was applied to right atrial appendage of 8 open-chest fluothane-anesthetized dogs. AP of a single subepicardial cell was successfully recorded in all 8 dogs (see Figure). Withdrawal of micropipette into a thin film of Tyrode's solution covering the epicardial surface gave a zero reference potential and allowed accurate measurement of resting and overshoot potentials. Characteristics (mean ± SEM) of AP of subepicardial cells of right atrial appendage at serum Na 142 and K 4.2 mEq/L are: heart rate 117 ± 7 beats/min, resting potential -80.8 ± 2.0 mV, overshoot potential 18.6 ± 2.1, upstroke dV/dt 20.8 ± 0.7 V/sec, 90% AP duration 257 ± 8 msec. In conclusion, the MCMH, by moving synchronously with the heart, allows reliable AP recording from atrial cells of the beating heart in situ, and may become an invaluable tool to assess the effects of drugs on atrial cells and to accurately measure sino-atrial conduction of the in situ heart in animals.



ELECTROPHYSIOLOGY OF THE CANINE SINUS NODE DURING CARDIOPULMONARY BYPASS: TECHNIQUE FOR LOCALIZATION AND RESPONSE TO COLD CARDIOPLEGIA. Jerry Gliklich, MD, Florence Chan, MD, Brian Hoffman, MD,FACC. Columbia University, New York New York.

High gain low frequency unipolar electrograms were recorded with ring or plaque electrodes from the epicardial surface of the heart in dogs undergoing cardiopulmonary bypass. The pacemaking region of the sinus node (PRSN) was defined as the site where the sinus node electrogram (SNE) revealed both primary negativity and an upstroke slope. In general, the PRSN was found on the RA, near the superior vena cava along the axis between the cavae. In some animals the PRSN was midway between the cavae. The core temperature (T) was decreased to 30°C prior to aortic cross-clamp and injection of cardioplegic solution. ([K]=30mM, T=4°C). Administration of cardioplegia rapidly produced slowing of ventricular conduction followed by ventricular standstill. Atrial activity was attenuated more slowly and SN potentials generally persisted longest. During quiescence, ventricular T=10-18°C and atrial T was 4-8°C higher. During cross-clamp the SNE occasionally revealed spontaneous rythmic SN activity, with a superimposed more rapid deflection corresponding to atrial activity. Phase 4 depolarization was clearly seen in these complexes and patterns of SN reentry were noted. As the core was warmed to 30°C prior to release of the aortic cross-clamp, SN activity invariably returned. In conclusion, it is possible to electrophysiologically localize the PRSN on the epicardium during open heart surgery, thereby possibly preventing SN damage in certain situations. In addition, the SN pacemaker appears to be more K and cold resistant than the atrium or ventricle.

EXCELLULAR RECORDING OF DIASTOLIC SLOPE IN DOGS AND HUMANS WITH HIS BUNDLE RHYTHMS •
Robert J. Hariman, MD, FACC; Chia-Maou Chen, MD, Sun H. Lau, MD; Anthony N. Damato, MD, Department of Cardiology, U.S. Public Health Service Hospital, Staten Island, N.Y.

His bundle (HB) rhythms were induced in 8 open chest dogs by exclusion of the sinus node. Recorded were bipolar atrial electrograms (E) using plaque electrodes sutured on the right atrial appendage and bipolar HB E using plunge electrodes. Unipolar HB E were recorded (time constant 0.1 sec, amplification 100 to 200 μV/cm) using the plunge electrodes paired with an indifferent plaque electrode on the superior vena cava. HB rhythms fulfilled the following criteria: During HB rhythms, a bipolar HB deflection preceded the ventricular complexes, which had QRS configuration and H-V interval identical to those during sinus rhythm or atrial pacing. The unipolar HB E showed negatively directed diastolic slope (DS), with a dV/dt of 0.1-5mV/sec,preceding the bipolar HB deflection. Vagal stimulation and/or I.V acetylcholine (10 mg) injection produced slowing of HB rhythms associated with a decrease in the dV/dt of DS. Similarly, overdrive suppression following atrial pacing was accompanied by a decrease in the dV/dt of DS. The responses of DS to vagal stimulation, acetylcholine and atrial pacing, which are similar to those of phase 4 depolarization, demonstrate that DS truly represents the pacemaker activity in the HB area. In one patient with a suspected HB rhythm, similar DS was recorded using an electrode catheter in the HB area paired with an indifferent electrode catheter in the superior vena cava at similar time constant and amplification. These results are important in the localization and characterization of abnormal impulse formation in the in vivo heart.

SINUS NODE EXCISION - A STUDY OF ATRIAL SUBSIDIARY PACEMAKERS - A CANINE MODEL OF THE SICK SINUS SYNDROME
John F. Moran, MD, FACC; Lynn Rinkema, BS, Walter C. Randall, PhD, FACC; Rolf M. Gunnar, MD, FACC, Loyola University Medical Center, Maywood, Il

Symptoms in the sick sinus syndrome are caused by dysfunction of the sinus node as well as failure of subsidiary pacemakers. Normal subsidiary escape pacemakers would potentially allow patients to remain asymptomatic. Dogs were surgically instrumented with high and low right atrial and left atrial electrodes. Later these animals were studied while conscious with overdrive atrial pacing and the atrial extrastimulus technique at two different drive cycles. Leads I, II, III and four atrial electrograms were recorded. Digoxin (0.05mg/Kg), propranolol (0.5mg/Kg) and atropine (0.1mg/Kg) were administered and the pacing study repeated. Sinus node recovery time averaged 900 mSec and shortened with faster pacing rates. Sinoatrial conduction time averaged 72 mSec. The sinus node was then surgically removed and the pacing studies with drugs were repeated. All studies were completed within 2 weeks in any single dog. Overdrive atrial pacing caused marked suppression of all subsidiary pacemakers with recovery times in the range of 4,000 to 10,000 mSec. Near syncope was frequently observed. The atrial extrastimulus technique caused marked suppression of the subsidiary atrial pacemakers. Propranolol and Digoxin lengthened this suppression and atropine shortened it. If the conduction time was calculated on those cycles demonstrating reset, it averaged 74 mSec. Atrial flutter and tachycardia were frequently induced. Pacemakers shifted from high to low activation and vice-versa. Conclusions: Sinus node excision allows evaluation of subsidiary pacemakers in chronic canine models. These pacemakers are initially very unstable and demonstrate marked suppression to overdrive or atrial extrastimuli.

EFFECTS OF $[K+]_o$ ON MEMBRANE POTENTIAL, DELAYED AFTERDEPOLARIZATIONS AND TRIGGERED ACTIVITY IN ATRIAL FIBERS OF THE CANINE CORONARY SINUS
Berthold Henning, M.D. and Andrew L. Wit, Ph.D., College of Physicians and Surgeons of Columbia University, New York, N.Y.

Delayed afterdepolarizations (DAD's) in fibers in the coronary sinus can reach threshold in the presence of catecholamines and result in rhythmic activity that may cause arrhythmias. Since $[K+]_o$ in coronary sinus blood may vary over a wide range, we investigated the effects of $[K+]_o$ (2.7 - 10 mM) on transmembrane potentials of atrial fibers in small coronary sinus preparations (2 mm long, 40-100μ in diameter) superfused in a fast flow system. DAD's with amplitudes of 5 mV or less followed action potentials stimulated at cycle lengths (CL's) of 10,000-5,000 msec when the level of resting membrane potential (RMP) was high (-80 to -99 mV) in superfusates containing 0.01 - 0.25μg/ml epinephrine and 2.7 mM $[K+]_o$. Triggered activity occurred when stimulus CL was sufficiently decreased. Exposure of the preparation to 4,6,8 and 10 mM $[K+]_o$ decreased resting membrane potential. DAD amplitudes increased, reaching a maximum of 10-20 mV at membrane potentials in the range of -60 to -50 mV, when the $[K+]_o$ was less than 8 mM. Triggered activity occurred at longer stimulus CL's. This suggests that the amplitude of coronary sinus DAD's are voltage dependent. At 8 to 10 mM $[K+]_o$ DAD amplitudes were reduced at all levels of membrane potential suggesting that the increase in membrane conductance which probably occurs at the higher $[K+]_o$ prevents the voltage dependent increase in DAD amplitude. Nevertheless, triggered activity was still easier to induce, probably because of the decreased difference between RMP and threshold potential. Therefore, an increase in coronary sinus blood [K+] should enhance the occurrence of triggered arrhythmias.

PHARMACOLOGY: CALCIUM ANTAGONISTS II
4:00-5:30

RELATIONSHIP BETWEEN PHARMACODYNAMICS AND MYOCARDIAL CONCENTRATION OF VERAPAMIL

Deborah L. Keefe, MD; Sandra R. Harapat, BS; Robert E. Kates, PhD, Division of Cardiology, Stanford University Medical Center, Stanford, CA.

Plasma drug concentrations are often measured to predict drug effect and avoid toxicity. The use of plasma levels is predicated on the assumption that they are in equilibrium with effector site levels, however the relationship between plasma and actual tissue concentrations at effector sites is not well understood. The relationship between the concentration of verapamil (V) in the plasma and in myocardium and drug effect as measured by %PR interval prolongation (%PRΔ) was studied in open-chested anesthetized dogs. Blood samples, myocardial biopsies, lead II ECG recordings, and arterial pressure tracings were obtained before and at 10,20,30,40,60,80,100,120,150, 180,210,240 and 300 minutes after the intravenous administration of V (0.5mg/kg) over 5 minutes. Verapamil concentrations in plasma and myocardium were measured by high pressure liquid chromatography. Verapamil administration resulted in a marked PR interval prolongation (average maximum 70 ± 30%). Two of the 6 dogs developed transient 2:1 AV block at levels of V above 3.65μg/gm of tissue in myocardium and 168ng/ml in plasma. The drug was concentrated in the myocardium reaching an average peak of 3.15 ± 0.87μg/gm of tissue which was more than 10 times the simultaneous mean plasma level of 245 ± 86ng/ml. The %PRΔ correlated well with myocardial concentration ($p<.001$). Myocardial kinetics were similar to plasma kinetics although the correlation of %PRΔ with myocardial level was somewhat better than that for plasma level. Both myocardial and plasma V levels correlated well with the degree of atrio-ventricular block and plasma levels of V are predictive of drug effect.

CONCENTRATION DEPENDENT HEART RATE SUPPRESSION WITH VERAPAMIL

Janice B. Schwartz, MD; Deborah Keefe, MD; Flora Peters, RN; Robert Kates, PhD; Donald C. Harrison, MD, Stanford University, Stanford, California

The relationship between serum Verapamil (V) concentration and heart rate suppression was studied in 5 patients with chronic atrial fibrillation. Following the determination of V pharmacokinetics in each patient using a 3 compartment model, V infusions were given to reach 4 steady-state levels: 15 ng/ml, 30 ng/ml, 60 ng/ml, and 120 ng/ml. At baseline and at each steady-state level, resting heart rate and heart rate after dumbbell exercise, and after sublingual nitroglycerin (NTG) was determined.

	Verapamil Concentration (ng/ml)				
	0	15	30	60	120
Resting Heart Rate	104	75	73	66	62
% Reduction					
Resting Heart Rate		24%	29%	34%	40%
$\bar{p}$ Dumbbell		20%	23%	30%	37%
$\bar{p}$ NTG		24%	25%	33%	42%

Serum concentrations of 15 or 30 ng/ml V produced significant ($p<.02$) suppression of resting, exercise and NTG stimulated heart rate. Increasing the V concentration to 60 or 120 ng/ml produced a further + significant ($p<.05$) decrease in resting, exercise and NTG stimulated heart rate. There were no significant differences between the effects of 15 vs. 30 or 60 vs. 120 ng/ml V.

Conclusion:

The serum concentration of Verapamil relates to the magnitude of suppression of resting, exercise, and NTG stimulated heart rates and can provide a guideline to clinical effects.

DIFFERING EFFECTS OF VERAPAMIL RELATIVE TO VARYING LEVELS OF MYOCARDIAL PERFORMANCE IN PATIENTS WITH CORONARY ARTERY DISEASE

Christopher Y.C. Chew, MD; Harvey S. Hecht, MD, FACC; Stephen Schnugg, MD; James Hopkins, BS; Bramah N. Singh, MD, FACC, Wadsworth VA Hospital, Los Angeles, Ca.

Verapamil (V) interferes with EC coupling in cardiac muscle and may exert significant negative inotropism. Accordingly, the intravenous effects of Verapamil (0.145 mg/kg over 2 mins and 0.005 mg/kg infusion) on left ventricular radionuclide ejection fraction (EF) and hemodynamics were evaluated in 25 pts with coronary artery disease including 8 with acute myocardial infarction. The data (M±S.D.) for pts (n=22) with PCW <18 mmHg are:

	C	V	P
HR	74±10	77±11	<0.05
BP	98±12	83±12	<0.001
PCW	10±3	12±3	<0.001
SI	41±10	44±10	<0.01
SVR	1424±320	1104±304	<0.001
EF(%)	52±18	56±9	NS

(C=pre-V; PCW=mean pulmonary capillary wedge; SI=stroke volume index; SVR=systemic vascular resistance; N.S.=not significant. Three patients with heart failure (PCW >20 mmHg; EF 26±8%) deteriorated clinically with an increase in PCW 26±5 to 33±3, a decrease in SI 33±5 to 28±5 with the development of pulmonary hypertension.

Conclusion: 1) Verapamil in coronary artery disease pts with PCW <18 mmHg exerts minimal depression on myocardial function; 2) in patients with heart failure (PCW >20 mmHg) Verapamil causes further deterioration and thus should be used with great caution.

EFFECT OF VERAPAMIL ON LEFT VENTRICULAR FUNCTION: RANDOMIZED, PLACEBO-CONTROLLED STUDY

Ronald E. Vlietstra, MD, FACC; Maria A. Farias, PhD; Robert L. Frye, MD, FACC; Hugh C. Smith, MD, FACC; Erik L. Ritman, MD, Mayo Clinic, Rochester, MN.

At cardiac catheterization, 25 pt were allocated by a random, double-blind method to intervention with placebo (saline) or verapamil (0.2 mg/kg total by bolus and 10-min infusion). Control and immediate postintervention hemodynamic measurements and left ventriculography allowed estimation of the values shown in the table below (MAP = mean arterial pressure; $+\bar{p}$ dTw/dt = peak rate of anterior wall systolic thickening; $-\bar{p}$ dTw/dt = peak rate of anterior wall diastolic thinning). Of the 25 pt (24 males, 1 female), 3, 3, 10, and 9 had 0, 1, 2, and 3 vessels narrowed ≥50%, respectively.

	Placebo (n=12)		Verapamil (n=13)*	
	Before	After	Before	After
Heart rate, beats/min	68	70	68	70
MAP, mm Hg	103	109	105	89†
CI, liters/min/m^2	2.9	2.9	2.8	3.1†
LV end-diastolic pressure, mm Hg	17	19	16	19
End-diastolic volume index, ml/m^2	91	89	94	102†
End-systolic volume index, ml/m^2	37	34	39	41
Ejection fraction, %	60	62	58	59
$+\bar{p}$ dTw/dt, mm/sec	35	35	27	25
$-\bar{p}$ dTw/dt, mm/sec	34	33	30	29

*For ventriculogram data, n=9. †$P<0.01$, paired t test. Hemiaxial shortening, for placebo and verapamil groups, decreased >10% in 4/48 and 8/48 segments and increased >10% in 8/48 and 9/48 segments, respectively ($\chi^2=1.52$, $P>0.1$). This statistical analysis indicates that verapamil lowers MAP, raises CI, and has little effect on LV function.

SUSTAINED BENEFICIAL EFFECT OF NIFEDIPINE IN CHRONIC REFRACTORY HEART FAILURE.

Fulvio Bellocci,M.D.;Gerardo Ansalone,M.D.;Enrico Scabbia,M.D.;Vincenzo Affinito,M.D.;Pietro Santarelli,M.D.; Franco Loperfido,M.D.;Paolo Zecchi,M.D.
Catholic University of Sacred Heart,Rome,Italy.

NIFEDIPINE (N) is a calcium antagonist drug which induces vascular smooth muscle relaxation. We have studied acute and chronic hemodynamic effects of N in 8 patients(pts) with refractory congestive heart failure(CHF)to evaluate the clinical use of N as a ventricular unloading agent. All pts had idiopathic cardiomyopathy and were in NYHA functional class III or IV. Measurements were recorded before and after the 20 mg oral dose of N and were repeated after 2 months of oral N(20 mg every 6 hours). Measurements included:heart rate(HR),bpm;mean blood pressure(MBP),mmHg;left ventricular filling pressure(LVFP),mmHg; cardiac index(CI),L/min/M^2;stroke volume index(SVI), ml/beat/M^2;total systemic vascular resistance(TSVR),dsc^{-5}; HR x systolic BP product(MVO_2 index). "p < 0.01 or below.

	HR	MBP	LVFP	CI	SVI	TSVR	MVO_2
Control	81	90	26	1.9	23	2250	10530
Initial	87	73"	19"	3"	34"	1250"	10005
2Months	84	76"	20"	3.1"	37"	1100"	9912

All pts had symptomatic improvement of at least one NYHA functional class.Thus,we conclude that N acutely raises CI and SVI and lowers LVFP and TSVR,and the hemodynamic responses are still evident following long-term therapy. These data support the use of N as an effective unloading agent for chronic therapy of CHF.

ANGIOGRAPHIC DYE RELAXES CANINE CORONARY ARTERY BY A NON-OSMOTIC MECHANISM

Karen I. Bentley, BS; Malcolm Clark, Philip D. Henry, MD, FACC. Washington University, St. Louis, MO.

During coronary arteriography the coronary vessels are briefly exposed to very high concentrations of angiographic dye. To characterize the effects of Renografin 76 (Na-diatrizoate, 1689 mosmol/liter) on coronary vasomotion, isolated canine coronary arteries (n=35) were mounted in a myograph for the recording of isometric tension, and exposed to oxygenated Krebs buffer containing graded doses of dye or iso-osmotic solutions of NaCl, Na_2SO_4, Na-tartrate, Na-ascorbate, KCl, and mannitol. Low doses of dye (< 3 ml/100 ml Krebs) evoked strong, sustained relaxations, and largely suppressed contractions elicited by 10^{-6}M ergonovine. High doses (4-16 ml/100 ml) produced dose-dependent spasms which were completely reversible upon removal of the dye. The other agents evoked no or minimal transient relaxations and acted as constrictors. The constrictor potency was KCl > dye > Na-tartrate > Na-ascorbate > mannitol > Na_2SO_4 > NaCl. Therefore, nonpermeating non-ionic solute (mannitol) and Na-salts with variously permeant anions did not mimic the effects of Na-diatrizoate. Verapamil, nifedipine, and nitroglycerin (all 10^{-6}M) relaxed contractions produced by KCl by > 80%, but reduced those induced by dye or Na-salts only by < 10%. Thus, low-dosed dye elicited relaxations by a non-osmotic mechanism, and higher doses precipitated spasms which were unresponsive to potent vasodilators. Results raise the possibility that dye may attenuate spontaneous or ergonovine-induced spasms during arteriography. Also, multiple injections or stagnant flow due to ventricular fibrillation might expose coronary smooth muscle to high concentrations and precipitate refractory spasms.

CLINICAL UTILITY OF PLASMA VERAPAMIL LEVELS IN PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY

Martin B. Leon, MD; Douglas R. Rosing, MD; Taysir M. Jaouni, MS; Henry M. Fales, PhD; Stephen E. Epstein MD, FACC; NHLBI, Bethesda, Md.

A highly sensitive, reproducible high pressure liquid chromotography assay was used to determine the importance of plasma verapamil levels (PVL) in guiding therapy of patients with hypertrophic cardiomyopathy. In 80 patients on chronic oral verapamil therapy, there was marked variability between patients in PVL for each dosage.

dose (mg/day)	240	360	480	640
mean PVL±2SD (ng/ml)	84±72	163±172	174±208	258±170

In contrast, variability in peak and trough PVL for a given patient was relatively small (verapamil peak/trough ratio for 23 patients=1.66±.07). PVL in 27 clinical responders (R), with improvement in NYHA functional class and >15% increase in exercise capacity, were not different from 15 nonresponders (NR) (R=153±11, vs NR=175±18 ng/ml; NS). Also, in 6 patients with atrial fibrillation, there was a poor correlation between PVL and decrease in ventricular response (r=0.52) after a single 80 mg verapamil tablet. Moreover, PVL in 24 patients with serious electrophysiologic or hemodynamic side effects from verapamil ranged from 30 to 540 ng/ml and the mean PVL (201 ±23 ng/ml) was no different from the R or NR.
Thus, in patients with hypertrophic cardiomyopathy on verapamil therapy 1) there is marked interpatient variability in PVL, which may be due to differences in first pass hepatic metabolism, 2) PVL are similar in R, NR, and patients with serious side effects. PVL are therefore of limited usefulness in predicting therapeutic or toxic effects in patients with hypertrophic cardiomyopathy.

DOPPLER SONES QUANTITATION OF CORONARY BLOOD FLOW IN MAN DURING DIPYRIDAMOLE CORONARY VASODILATATION

Kent L. Richards, MD, FACC; Sherman G. Sorensen, MD, FACC; Craig Hartley, PhD; William P. Dole, MD, University of Texas Health Science Center and Veterans Administration Hospital, San Antonio, Texas

We studied changes in coronary artery flow during intravenous dipyridamole (DP) induced coronary vasodilatation (0.14 mg/kg/min for 4 min) in 6 patients using a unique Sones angiographic catheter equipped with a 20 mHz pulsed doppler transducer at its tip and a transformer electrical coupler at its hub. Heart rate, intravascular pressure, coronary blood velocity, and cardiac output were measured before and after intravenous DP. Coronary artery blood flow was also measured during DP vasodilatation with handgrip and coronary angiography. Mean ±SD heart rate (HR, beats/min), blood pressure (SBP), cardiac output (CO), coronary blood flow (CBF, as KiloHz) for normal (NL) and abnormal (ABN, >50% stenosis) were:

	HR	SBP	CO	CBF/NL	CBF/ABN
CONTROL	70±12	122±24	7.1±1.8	2.1±.86	3.8±1.1
DIPYRIDAMOLE	86±13	110±17	7.7±2.7	4.1±1.7*	3.6±1.4

Handgrip failed to increase CBF in NL arteries (4.1 KHz vs 4.4 KHz). Stenotic arteries (pre and post DP) and normal arteries (post DP) demonstrated blunted hyperemic flow response to contrast arteriography (4.43 vs 4.75; normal increase 2-3.4 fold). Two normal patients failed to increase CBF with DP; both developed arterial hypotension and diastolic pressures less than 60 mmHg with DP. We conclude that 1) CBF increases in NL arteries but not ABN arteries after DP, 2) varied responses to DP may occur due to altered hemodynamics or dose response.

*p<.05

EFT VENTRICULAR RESPONSE TO EXERCISE AFTER ANTERIOR YOCARDIAL INFARCTION: • DIFFERENCES BETWEEN PATIENTS WITH INGLE AND MULTIVESSEL CORONARY ARTERY DISEASE.
rthur T.H. Tan MB, Norman Sadick MB, Roger F. Uren MB hillip J. Harris MB FACC, David T. Kelly MB FACC. allstrom Institute of Cardiology, Sydney, Australia.

Patients with single or multivessel disease may have mpaired LV function at rest after anterior transmural yocardial infarction. To determine whether the LV response to exercise was different in these two groups, 26 atients with previous extensive anterior myocardial infarction from total left anterior descending artery (LAD) cclusion underwent exercise testing with equilibrium adionuclide ventriculography. Fifteen patients (SVD) had solated occlusion and 11 patients (MVD) had one or more dditional ≥70% stenosed coronary arteries.

The mean maximum heart rates in SVD (148±5) and MVD 146±5) patients were similar. Seven MVD patients but no VD patients developed angina and/or ischaemic ST changes ith exercise. In SVD patients, ejection fraction (EF) id not change from rest (0.32±0.03) to peak exercise 0.30±0.03) because there was a similar increase in end ystolic volume (ESV; 19%±4%) and end diastolic volume EDV; 16%±4%). In MVD patients EF decreased from 0.32± .03 to 0.23±0.02 ($p<0.01$) because of a disproportionate ncrease in ESV (45%±13%) compared to EDV (27%±7%).

After extensive anterior myocardial infarction resting EF is a poor index of exercise capacity. The increase n cardiac output during exercise in patients with SVD nd previous anterior infarction is heart rate dependent ecause stroke volume does not change. In patients with IVD the cardiac output response to exercise is attenuated ecause end systolic volume increases and stroke volume ecreases. This response to stress after myocardial nfarction may be important for early identification of atients with a poor prognosis due to residual ischaemic yocardium.

ASYMPTOMATIC LEFT MAIN CORONARY ARTERY DISEASE
Fayaz A. Shawl, MD; MRCP; Mitchell L. Mutter, MD; Dennis J. Donohue, MD; Robert D. Siama, MD; Rus Zajtchuk MD; James E. Davia, MD; Walter Reed Army Medical Center, Washington, D.C.

The prognosis, detection, and natural history of severe, asymptomatic coronary astroy disease remain difficult clinical problems. Epidemiologic studies of unexpected death and post-mortem studies of silent myocardial infarction suggest that this entity may be more common. We reviewed 89 consecutive patients with significant left main coronary artery disease (LMD), defined as 50% or greater reduction of luminal diameter. Of this group 10 pts (11%) were asymptomatic (ALMD) and 79 pts (88%) were symptomatic. All 10 ALMD pts were males with a mean age of 53 years (range 40-65). Treadmill test (TMT) were performed in this group for the following reasons: EKG abnormalities, 6; pre-jogging evaluation 2; risk factor evaluation 2. The TMT showed 2mm or greater ST depression in 7/10 (70%) and 1-2mm in 3/10 (30%). Similar TMT results were obtained in the SLMD group, although 2 patients had negative responses. The degree of stenosis of the left main coronary artery and the frequency of 3-vessel disease was similar in both groups. LV functions in ALMD group was excellent as manifested by a normal ejection fraction and normal wall motion in all 10 pts and a normal left ventricular end-diastolic pressure (LVEDP) in 70%, whereas in SLMD group 63% had an abnormal ejection fraction, 62% had wall motion abnormalities and 57% had a normal LVED.
In conclusion 1) 11% of LMD patients were asymptomatic 2) No significant difference was found in the TMT response and anatomy in the ALMD and SLMD group and 3) the ALMD group had much better LV functions when compared to the SLMD group.

ROGNOSTIC SIGNIFICANCE OF LEFT MAIN EQUIVALENT STENOSIS
lartin J. Conley, M.D., Victor S. Behar, M.D., F.A.C.C., rank E. Harrell, Ph.D., Robert M. Califf, M.D., Robert . Rosati, M.D., Duke University Medical Center, Durham, lorth Carolina

Concomitant ≥75% stenosis of the left circumflex proximal o the first marginal and ≥75% stenosis of the left nterior descending proximal to the first septal perforator and the first anterolateral have been considered o carry risk equivalent to ≥75% left main stenosis. The urpose of this study was to determine the prognostic ignificance of left main equivalent (LME) stenosis. mong 1527 consecutive medically treated patients with ignificant (≥75%) coronary artery disease, long-term urvival was significantly ($p=0.001$) lower for 90 patients ith ≥75% left main (LM) stenosis than for 57 patients ith LME stenosis:

	6 mo.	1 yr.	2 yrs.	3 yrs.	4 yrs.	5 yrs.
LM	73%	66%	52%	42%	40%	36%
LME	84%	76%	72%	63%	61%	54%

ultivariable analysis using a series of baseline haracteristics which we have previously demonstrated to e independent predictors of survival (including left entricular ejection fraction and number of vessels with ignificant stenoses) confirmed the prognostic importance f LM stenosis ($p<0.001$) but failed to demonstrate rognostic importance for LME stenosis ($p>0.20$). LME tenosis, therefore, does not carry risk equivalent to LM tenosis.

TOTAL OCCLUSION OF THE LEFT MAIN CORONARY ARTERY: THE CASS EXPERIENCE.
Samuel H. Zimmern, M.D., William J. Rogers, M.D., F.A.C.C., Peter R. Bream, M.D., Bernard R. Chaitman, M.D., F.A.C.C., Martial G. Bourassa, M.D., F.A.C.C., Kathryn A. Davis, Ph.D., Denis H. Tyras, M.D., Robert Berger, M.D., F.A.C.C., Lloyd Fisher, Ph.D., F.A.C.C., Melvin P. Judkins, M.D., F.A.C.C., Michael B. Mock, M.D., F.A.C.C., and Thomas Killip, M.D., F.A.C.C. University of Alabama in Birmingham, Birmingham, Alabama.

Total occlusion of the left main coronary artery (100%-LMCA) was confirmed on review of cineangiograms in 12 (0.05%) of the 23,349 patients (pts) entered into the Coronary Artery Surgery Study (CASS) prior to coronary surgery. These 12 pts are the largest reported group with 100%-LMCA.

Mean age at presentation was 58.9 yrs (range 44-80). Ten pts were male. Eleven pts had angina pectoris (AP) as their presenting complaint; 10 had Class III or IV AP; 4 had unstable AP. Chest pain first had been noted a mean of 231 wks (range 3 wks-14 yrs) prior to entry; the presenting level of symptoms had existed a mean of 24.4 wks (2-104 wks). Six pts had a myocardial infarction and 2 had congestive failure prior to entry. One pt presented with only a changed ECG.

During follow up 4 pts died a mean of 43.5 days after entry; 8 were living a mean of 37.6 mos after entry. The mean age on entry in the group that died was 70 yrs and in the surviving group 53.2 yrs. Seven pts had coronary artery bypass graft surgery (CABG); of these, 6 (86%) were surviving a mean 41.7 mos after CABG; 4 of these pts were free of angina. Five pts did not have CABG; of these, 2 (40%) were surviving a mean of 24 mos after entry, and 1 was free of angina.

Conclusions: 1.) Total occlusion of the left main coronary artery is a rare lesion. 2.) Most pts present with severe angina of prolonged duration. 3.) Advanced age worsens long-term prognosis. 4.) Prolonged survival and improvement of symptoms may occur following CABG. 5.) Long-term survival without angina is possible even without CABG.

LEFT VENTRICULAR DYSFUNCTION FROM HYPERTROPHIC CARDIOMYOPATHY AND VALVULAR CAUSES
4:00-5:30

LONG-TERM EFFECTS OF VERAPAMIL ON LEFT VENTRICULAR DIASTOLIC FILLING IN PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY

Robert O.Bonow, M.D., Douglas R.Rosing, MD, Stephen L. Bacharach, PhD, Michael V.Green, MS, Lewis C.Lipson, MD, John R.Condit, BS, Kenneth M.Kent, MD,FACC, and Stephen E.Epstein, MD, FACC, NHLBI, Bethesda, Maryland

Oral verapamil (V) therapy improves exercise tolerance and reduces symptoms in many pts with hypertrophic cardiomyopathy (HCM). We previously showed, using high resolution radionuclide LV time-activity curves, that abnormalities in LV diastolic filling (reduced peak LV filling rate (PFR) or prolonged time to PFR) are improved in pts with HCM after 1 week of V therapy, while systolic function is unaltered. To determine whether these improvements persist during long-term V therapy, we restudied 17 pts after 1 year of therapy before and after withdrawal from V. We found the following changes (mean ±SD) in PFR, measured in end-diastolic volumes (EDV)/sec, and in time to PFR:

	PFR (EDV/sec)	P		Time to PFR (msec)	P	
Control	3.2±1.1	<.001		170±43	<.01	
V-1 week	4.1±1.3		NS	157±31		<.05
V-1 year	3.5±1.3	<.005		187±39	<.001	
Control-1yr	3.0±1.0	<.005		204±46	<.05	

LV systolic function (ejection fraction, peak ejection rate and ejection time) did not change after 1 week of V, after 1 year of V, or after withdrawal from V at 1 year. Thus, 1) chronic V therapy does not alter LV systolic function in pts with HCM, and 2) initial improvements in LV diastolic filling induced by V decline over the course of 1 year, although V continues to exert persistent reversible beneficial effects in diastolic filling.

HYPERTROPHIC CARDIOMYOPATHY: MEASUREMENT OF CATION UPTAKE

William J.McKenna, M.D., Roger M.Allan, MB,FRACP, Peter Horlock, LRIC, J.C.Clark, BSc, P.M.Grant, H.A. O'Brien, Celia M.Oakley, MD,FACC, John F.Goodwin, MD,FACC, Andrew P.Selwyn, MB, MRCP. Royal Postgraduate Medical School, MRC Cyclotron Unit, Hammersmith Hospital,London, UK and Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

The metabolic characterisation of myocardial tissue in hypertrophic cardiomyopathy (HCM) is under investigation. Positron tomography permits the quantitative assessment of the regional cation uptake by myocardium. Six patients with HCM and asymmetric septal hypertrophy and 6 normal subjects were studied. Transmission scans at 4 myocardial levels, 1.5 cm apart, were performed to later correct for tissue attenuation. Emission tomograms, at these 4 levels, were performed during the steady state intravenous infusion of Rubidium 82 (82Rb) ($t_{1/2}$= 78 sec) and 30 sec after cessation of the infusion. Computer reconstructed images were recorded on matrix printouts and the myocardium delineated. The arterial concentration of 82Rb was determined from the steady state imaga data and extraction x flow was calculated. Values were obtained for regions within the interventricular septum and the left ventricular posterior wall. Partial volume effects were corrected using M mode echocardiographic measurements. The ratio of left ventricular posterior wall to septal counts was calculated for all studies. The mean ratio for patients with HCM, 1.16 ± 0.054 (SEM), was significantly different from the mean ratio for the normals 1.02 ± 0.068 (P<0.005). These results in patients with HCM and asymmetric hypertrophy show regional differences in cation uptake which are not seen in normal subjects. These results suggest an abnormality of cation extraction and/or tissue perfusion in hypertrophic cardiomyopathy. (82 Strontium courtesy of Los Alamos).

MYOCYTE DISARRAY DEVELOPS IN PAPILLARY MUSCLES RELEASED FROM NORMAL TENSION AFTER MITRAL VALVE REPLACEMENT

John S. Pirolo, BS, Grover M. Hutchins, MD, G. William Moore, MD, PhD, and Myron L. Weisfeldt, MD, FACC, The Johns Hopkins Medical Institutions, Baltimore, Maryland

Papillary muscles have an orderly array of myocytes aligned parallel to lines of tension. We examined the histologic effects of abrupt removal of tension on myocytes in left ventricular papillary muscles of 82 patients with mitral valve replacements, of whom 16 died at operation, 46 within one month, and 20 from 31 days to 15 years post-operation. Focal contraction band necrosis in 54 (66%) cases and fibrosis in 69 (84%) cases occurred in all three survival groups. Zonal lesions, sarcoplasmic condensations adjacent to intercalated discs, in 49 (60%) cases were prominent early, and correlated negatively with survival time (p<0.005). Myocyte disarray in 25 (30%) cases developed progressively with longer survival time (p<0.001) to become a pattern of an interconnecting, random network of myocytes. Myocyte atrophy in 16 (20%) cases correlated with degree of acquired disarray (p<0.001). Multivariate regression analysis with these five histologic features as predictors of survival time showed significant prediction by myocyte disarray only (p<0.001). Since the post-surgical papillary muscles studied approach an idealized isotonic contraction, it appears that myocyte disarray may be acquired over time in such a physical state. The study supports the concept that myocyte orientation arises as a direct consequence of force distribution in the myocardium.

ABNORMAL MITRAL ANNULAR CONTRACTION IN CARDIOMYOPATHIES AND CORRELATION WITH LEFT VENTRICULAR FUNCTION.

John A. Ormiston, MB ChB, FRACP, Pravin M. Shah, MD, FACC, Chuwa Tei, MD, Harvey Hecht, MD, FACC. University of California, and Wadsworth VA Medical Center, Los Angeles, California.

Wide angle phased array two-dimensional echocardiography was used to examine mitral annular areas and changes during the cardiac cycle in 12 normals (Nl), 8 patients (pts) with dilated cardiomyopathy (DCM) and 9 with hypertrophic cardiomyopathy (HCM). The echocardiographic transducer was placed over the palpable left ventricular apex and multiple planes around the circumference of the annulus recorded by sequential 30° rotations of the transducer. Annular diameters from each plane were used to reconstruct the annular circumference for selected times during the cardiac cycle. Enclosed areas were planimetered. Annular area reduction was calculated by expressing as a percentage the ratio (maximum diastolic area minus minimum systolic area) ÷ (maximum diastolic area). Radionuclide ejection fraction (EF) was obtained by equilibrium blood pool imaging after in vivo red blood cell labelling with technetium^{99m} in 7 DCM pts, 5 HCM pts and 1 Nl. Systolic annular area reduction was 27±3% (mean±SD) in Nls 10±6% in DCM and 39±3% in HCM. The differences between Nl and DCM as well as Nl and HCM were significant (p<0.001). There was a high correlation between systolic annular area reduction and radionuclide EF (r=0.935, SEE=6).

In conclusion 1) systolic annular area reduction is decreased in DCM and increased in HCM, 2) a high correlation between annular area reduction and EF suggests a direct relationship with pump function.

LEFT VENTRICULAR DYSFUNCTION IN PATIENTS WITH MITRAL REGURGITATION

Lewis C. Lipson, MD, Kenneth M. Kent, MD, FACC, Robert O. Bonow, MD, Douglas R.Rosing, MD, Charles L.McIntosh, MD, Michael Jones, MD, Andrew G.Morrow, MD, Stephen E. Epstein, MD, FACC, NHLBI, NIH, Bethesda, Md.

To determine optimum time for valve replacement in pts with mitral regurgitation (MR), we prospectively studied echo, radionuclide (RN) angiography, and hemodynamics in 21 pts with MR and severe symptoms who subsequently underwent operation (op). These studies were compared to those obtained in 17 mildly symptomatic pts who were followed (nonop). Pre-op, there were no significant differences between op and nonop pts in echo LV diastolic dimension (64±11 vs. 66±11), RN ejection fraction at rest (EFrest) (53±9 vs.51±8) or during exercise (EFex)(57±11 vs.56±12). At rest op pts had higher RA pressure (11±4 vs.5±3, p<.001) and PAW pressures (26±8 vs. 14±5, p<.001), but similar CI (2.3+.7 vs 2.5±.7, NS) compared to nonop pts. During supine exercise, despite similar elevations of PAW pressure (38±9 op vs. 31±14 nonop, NS) op pts had a lower CI (3.4±1.2 vs. 5.5±1.8, p<.005) than nonop pts. Postop, despite improvement in RA (11±4 to 8±4, n=13, p<.05) and PAW pressures (24±8 to 18±6, n=13, p<.05), CI was unchanged (2.2±.6 preop vs. 2.6±.8 postop, n=13, p<.05). Postop there was a marked reduction in EFrest (38±10 vs. 51±10 preop, n=13, p<.05) and EFex (41±12 vs.56±12 preop, n=12, p<.01); 10/13 pts had subnormal (<45%) EFrest and 11/12 pts had subnormal (<54%) EFex. Postop EFex was inversely related to preop LVDD and PAW at rest. We conclude that in pts with MR (1) LV dilatation occurs before severe symptoms develop and (2) by the time pts become severely symptomatic, irreversible LV dysfunction has occurred despite normal preop RN EF, a result of LV decompression into a low pressure LA.

LEFT VENTRICULAR EJECTION RATE DURING THE FIRST THIRD OF SYSTOLE IN PATIENTS WITH AORTIC INSUFFICIENCY

Lynne L. Johnson, MD, Mitchell Marshall, BS, Yvonne E. Johnson, MD, Paul J. Cannon, MD, FACC, Columbia U New York

In previous studies the rate of LV volume change during the first 1/3 of systole was shown to be a more sensitive index of cardiac performance than ejection fraction (EF) in coronary disease. To test the hypothesis that a non-invasive index of the ejection rate in early systole can also identify subtle abnormalities of LV performance in aortic insufficiency (AI) the rate of change of LV counts during the first 1/3 of systole was measured by first pass radionuclide angiography in 26 patients. By weighted least squares a monoexponential equation was fit to the LV counts obtained at 0.025 second intervals during the first 1/3 of systole; the slope was divided by the average counts in the first 1/3 to give a rate constant (RC) proportional to LV volume change during early systole.

The patients were divided into two groups based upon the response of EF to exercise (ΔEF). In group I resting EF was .59±.08 and increased .10±.04 during exercise; in group II resting EF was not different (.58±.08) but fell during exercise (-.08±.06) ($p<.001$). The RC obtained at rest was 15.7±4.0 in group I and was significantly lower in group II, 9.5±3.0 ($p<.001$). Using an RC of 12.0 as a cut-off and applying the Fisher exact test, separation of the groups was excellent ($p<.001$) with only one group I patient with RC<12.0 and 2 in group II with RC>12.0. When RC was plotted vs EF for the 26 patients, there was a significant direct relationship, $r = 0.76$ ($p<.01$) but with wide confidence limits.

The data indicate that a non-invasive index of the rate of LV volume change during the first 1/3 of systole can identify abnormal LV reserve in patients with AI and normal EF at rest.

DIASTOLIC MECHANICS OF THE HEART AND PERICARDIUM
4:00-5:30

SYSTOLIC LOAD DEPENDENCY OF LEFT VENTRICULAR RELAXATION IS INFLUENCED BY BETA ADRENERGIC TONE AND ABNORMAL SYNCHRONY.

Alvin S. Blaustein MD, William H. Gaasch MD FACC, John D. Carroll MD, Dan Adam PhD and Herbert J. Levine MD FACC. Tufts-New England Medical Center Hospital and Harvard-Beth Israel Hospital, Boston, MA.

The relation between LV relaxation velocity and systolic load (pressure) was examined in 18 open chest anesthetized (chloralose-morphine) dogs (constant heart rate,2 Hz). LV pressure (P) was measured with a micromanometer and the time constant (T,ms) of LV isovolumic P decline was taken as an index of LV relaxation velocity. A progressive increase in LV systolic P was produced by abrupt diastolic cross clamp of the descending thoracic aorta; the clamp was maintained for 3 beats and then released,thus generating 4 end systolic (ES) P-T coordinates. Over a wide range of ESP (95-200 mmHg.) the ESP-T relation was linear (least squares best fit, r=+0.98). By definition,the slope (k) of this relation reflects the load dependency of T.

Values of T and k were determined before (control, C) and after each of three interventions: isoproterenol (Iso), propranolol (Pro), and LV asynchrony (Asyn). Asynchrony was produced by RV free wall pacing; all other studies were performed with RA pacing. Data below are mean±SE; *=$p<0.05$: T_{120}=T at a common ESP of 120 mmHg.

	C	Iso	C	Pro	C	Asyn
T_{120}	26±2	22±3*	20±3	27±4*	24±2	30±3*
k	.16±.01	.09±.01*	.11±.01	.29±.04*	.09±.02	.25±.04*

Thus, the time constant of LV pressure decline is load dependent; this load dependency is decreased by isoproterenol and increased by propanolol and asynchrony. Changes in sympathetic tone presumably influence relaxation through subcellular or biochemical processes, while asynchrony likely influences the load dependency of T by changing the distribution of load over functioning myofibrils and/or by causing temporal dispersion of relaxation.

MECHANISMS OF LOAD INDEPENDENCE OF RELAXATION DURING HYPOXIA IN MAMMALIAN CARDIAC MUSCLE

Stanislas U. Sys; Philippe R. Housmans, M.D.; Eric R. Van Ocken, Ph.D.; Dirk L. Brutsaert, M.D., Ph.D. Dept.of Physiology, University of Antwerp, Antwerp, Belgium.

In mammalian cardiac muscle relaxation, which is very sensitive to the prevailing load, was recently shown to become largely load-independent during hypoxia. This effect was ascribed to a delayed removal of the activating myoplasmic calcium.

To further elucidate the underlying mechanisms of this effect of hypoxia, relaxation was now studied in 20 cat papillary muscles (29° C; 12/min; $(Ca^{2+})_o$ 2.5 mM) at low $(Ca^{2+})_o$ (1.0, 0.5, 0.375 mM) or after verapamil (10^{-6} M). Load dependence of relaxation was quantified by comparing force and time coordinates at the onset of the isometric relaxation phase in several afterloaded isotonic twitch contractions with the relaxation of the isometric control contraction. Low $(Ca^{2+})_o$, verapamil and hypoxia reversed relaxation from load-dependent into load-independent. Although low $(Ca^{2+})_o$ and verapamil had a more marked negative inotropic effect on the contraction phase than hypoxia, the reversal of relaxation from load-dependent into load-independent was significantly more pronounced with hypoxia. Even when hypoxia was superimposed on low $(Ca^{2+})_o$ or verapamil, the same marked degree of load dependence was attained as during hypoxia alone. The mechanisms by which low $(Ca^{2+})_o$ and verapamil result in load-independence of relaxation, probably by slowing down the removal of activating myoplasmic calcium, are still not fully understood. However, hypoxia exerts an additional disturbing effect on relaxation through other, probably energetically-linked aspects, e.g. the ATP-dependent detachment of the actinomyosin interactions.

THE EFFECT OF VERAPAMIL ON THE DIASTOLIC MECHANICS OF THE LEFT VENTRICLE

Peter Van Trigt, M.D.; Craig O. Olsen, M.D.; Gary L. Pellom, M.S.; Robert B. Peyton, M.D.; Robert N. Jones, M.D.; J. Scott Rankin, M.D.; Andrew S. Wechsler, M.D., Duke University, Durham, North Carolina

Verapamil (V), an antagonist of ionized calcium (Ca++) influx, has been shown to depress LV systolic performance; however, little is known of its effect on diastolic function. The effect of V on the diastolic mechanical properties of the LV was studied in 7 conscious dogs previously instrumented with epicardial ultrasonic dimension transducers to measure LV minor axis diameter. LV transmural pressure was measured with micromanometers. LV pressure and dimension data were recorded and computer analyzed during transient vena caval occlusions in the control state and following a 20 minute intravenous infusion of V (.01 mg/kg/min) which decreased peak LV pressure 131.0±2.6 to 117.3±2.2 mm Hg ($p<.01$), peak dp/dt 2043±260 to 1834±284 mm Hg/sec, and peak dL/dt -51.95±2.2 to -48.3±2.1 mm/sec ($p<.05$). Static diastolic diameters were normalized according to Lagrangian strain (ε), and the pressure strain data were fitted to $P=\alpha(e^{\beta\varepsilon}-1)$, where α and β are nonlinear elastic coefficients of the myocardium. Strain data (mean ± SEM) at specific end diastolic pressures (5,10,15,20 mm Hg) were compared during control and after V (*=$p<.05$).

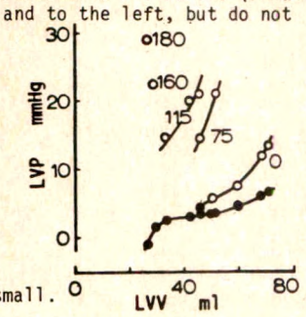
	$\varepsilon 5$	$\varepsilon 10$	$\varepsilon 15$	$\varepsilon 20$
Control	.078±.003	.117±.005	.146±.005	.168±.006
Verapamil	*.088±.004	*.132±.005	*.161±.006	*.188±.008

In addition, myocardial elastic constants were changed by V for each dog. Thus, V caused a significant shift to the right of the diastolic pressure-strain relationship, indicating an increase in LV diastolic compliance. These data suggest that by decreasing Ca++ influx into the region of the myofibrils, V impairs systolic function and alters the diastolic material properties of the myocardium.

SHIFTS IN LEFT AND RIGHT VENTRICULAR DIASTOLIC PRESSURE-VOLUME CURVES DUE TO PERICARDIAL EFFUSION AND TAMPONADE

John V. Tyberg, MD, FACC; Michael Junemann, MD; Helge Refsum, MD; Erik Carlsson, MD; Martin J. Lipton, MD, FACC CVRI, University of California, San Francisco, CA.

We studied the effects of pericardial effusion and tamponade on LV and RV pressure-volume (P-V) relations using computed tomography with contrast medium enhancement to measure pericardial and intracardiac volumes of 16 anesthetized closed chest dogs. The areas of the computed tomographic cross-sections were measured at 1 cm intervals from apex to base. We used flat saline-containing balloons to measure pericardial and pleural P. Pericardial effusion and tamponade, produced by infusing warmed dilute contrast medium, increased pericardial P by dilating the pericardium along its P-V curve. In the experiment shown open symbols represent LV P relative to atmospheric P; solid symbols represent transmural LV P (LV P - pericardial P). The numbers indicate the volume (ml) of pericardial fluid. Pericardial effusion and tamponade shift LV and RV diastolic P-V curves (relative to atmospheric P) upward and to the left, but do not affect the LV and RV diastolic transmural P-V curves. In pericardial effusion and tamponade elevated LV and RV diastolic P indicate elevated pericardial P; however, transmural ventricular diastolic P may approach zero and ventricular diastolic volumes may become very small.



QUANTIFICATION OF PERICARDIAL INFLUENCES ON DIASTOLIC FILLING OF THE LEFT VENTRICLE.

George S. Tyson, Jr., M.D., Craig O. Olsen, M.D., James W. Davis, M.S., J. Scott Rankin, M.D., David C. Sabiston, Jr., M.D., Duke University Medical Center, Durham, N.C.

In eight conscious, chronically instrumented dogs left ventricular (P_{LV}), pericardial (P_{PC}), and pleural (P_{PL}) pressures were simultaneously measured with matched micromanometers and minor axis left ventricular (LV) diameter was measured with ultrasonic transducers. During implantation, the pericardium was incised transversely at the base of the heart and then was precisely reapproximated so that its characteristics were minimally disturbed. Data were recorded during control conditions, during vena caval occlusions, and after volume loading such that LV diastolic transmural pressure (P_{LV}-P_{PL}) was varied from 0-25 mmHg. At normal diastolic volumes, the absolute P_{PC} varied with the P_{PL} through the respiratory cycle, but the transpericardial pressure (P_{PC}-P_{PL}) remained constant at approximately 0 mmHg. At maximum diastolic volumes obtained after volume loading, transpericardial pressure averaged 4.2 mmHg and accounted for less than 20% of LV transmural pressure. The exponential diastolic LV transmural pressure-dimension relationship remained essentially constant whether P_{PC} or P_{PL} was used as the external pressure; the differences observed were minimal and occurred at higher diastolic volumes. Thus, when measurements are made precisely, transpericardial pressure remains low over the entire physiologic range of measurements. Furthermore, the pericardium does not significantly affect diastolic filling of the LV at normal end diastolic volumes, and even at maximum volumes its influence is minimal.

ALTERATIONS IN LEFT VENTRICULAR GEOMETRY DURING INSPIRATION IN THE CONSCIOUS DOG.

Craig O. Olsen, M.D., Peter Van Trigt, III, M.D., Gary Pellom, M.S., Andrew S. Wechsler, M.D., J. Scott Rankin, M.D., Duke University Medical Center, Durham, N.C.

The mechanisms of respiratory variations in left ventricular (LV) function were investigated in eight conscious dogs instrumented with ultrasonic transducers to measure LV anterior-posterior (D_{AP}) and septal-free wall (D_{SF}) diameters. LV, right ventricular (RV) and pleural (Pl) pressures (P) were measured with matched micromanometers. Data were recorded during spontaneous deep inspirations (Mueller maneuver) and analyzed by digital techniques. During inspiration PlP decreased by -11.5±1.7 mmHg, LV transmural pressure (TMP=LVP-PlP) and D_{AP} increased, while LV transeptal pressure (TSP=LVP-RVP) and D_{SF} decreased. Data are presented (mean±SEM) for spontaneous deep inspirations at end expiration (EE) and end inspiration (EI):

	mmHg			mm	
	PlP	TMP	TSP	D_{AP}	D_{SF}
EE	-2.3±0.2	10.6±1.3	5.4±0.8	68.1±2.0	60.3±1.9
EI	-13.8±1.8	14.5±2.2	3.6±1.4	69.6±2.1	59.7±1.8
P(t)	<.01	<.05	<.05	<.01	<.05

Thus, during the respiratory cycle, D_{AP} varied directly with the TMP gradient while D_{SF} changed with the TSP gradient. With inspiration LV minor axis geometry deformed eccentrically possibly secondary to increased venous return to the RV which decreased the TSP gradient. Therefore, impaired filling of LV due to septal shifting may be one mechanism producing decreased LV stroke volume during spontaneous inspiration.

ECHOCARDIOGRAPHY: VALVULAR DISEASE
4:00-5:30

TWO-DIMENSIONAL ECHOCARDIOGRAPHIC IDENTIFICATION OF PROLAPSE OF INDIVIDUAL SCALLOPS OF POSTERIOR MITRAL LEAFLET

Bapineedu Gondi, MD; Navin C. Nanda, MD, FACC; James Hodsden, MD; University of Rochester Medical Center; Rochester, New York

The posterior mitral leaflet (PML) usually has 3 scallops and 1 or more of these scallops may be affected by myxomatous changes and prolapse into LA during systole. Echocardiographic identification of individual scallops has not been described previously. In 12 patients (pt) isolated PML prolapse was identified by real time two-dimensional echocardiography (ATL 90° sector scanner) in standard parasternal and/or apical four-chamber view. The mitral valve (MV) was then scanned from base to tip in short axis plane to view indentations which divided the posterior leaflet into scallops. M-mode tracings were obtained from the short axis views of the MV by passing a cursor through the scallop areas and were evaluated for systolic MV prolapse. In our experience, PML prolapse occurs in a supero-posterior direction and this technique detects the posterior component. Systolic prolapse into LA involved all scallops in 6 pt (50%), central and medial scallops in 5 pt (42%) and central scallop alone in 1 pt (8%). Auscultatory evidence for mitral regurgitation was more commonly seen in pt with 3-scallop prolapse (5/6 pt) than in pt with 2-scallop (2/5 pt). One pt with 3-scallop prolapse and another with 2-scallop prolapse had frequent ventricular premature beats. Echocardiographic identification of prolapse of individual posterior leaflet scallops may enhance our understanding of the syndrome and may correlate with clinical findings such as the degree of mitral regurgitation.

ECHOCARDIOGRAPHIC EVALUATION OF TRICUSPID ANNULUS SIZE AND FUNCTION IN NORMAL AND IN TRICUSPID REGURGITATION.

Chuwa Tei, MD, Pravin M. Shah, MD, FACC, John A. Ormiston, MD, Maylene Wong, MD. University of California, Los Angeles, and Wadsworth VA Medical Center, Los Angeles, CA.

Using wide angle phased array two-dimensional echocardiography, tricuspid leaflets and annular attachments were recorded by placing the transducer in an intermediate position between the left sternal edge and the apex. The transducer was then rotated and recordings obtained at 30° rotational intervals around the circumference of the tricuspid annulus. At each rotational interval, the largest annular diameter observed, at end of the P wave on EKG (max. diameter); and the smallest at midsystole (min diameter) were measured, and max and min annulus areas were reconstructed. Annular areas were planimetered and annular circumferences measured using a wheel. The annular area index (cm^2/m^2) and the annular circumference index (cm/m^2) were examined in 11 patients with tricuspid regurgitation (TR) secondary to long standing pulmonary hypertension or dilated cardiomyopathy; and 10 normal subjects (N). Annular area and circumference index in TR were significantly larger than N. However, their systolic reductions were signigicantly smaller than N.

	Area Index (cm^2/m^2)			Circumference Index (cm/c^2)		
	max	min	reduction	max	min	reduction
N(n=10)	3.7±0.6	2.1±0.3	42±4%	4.9±0.4	3.8±0.3	23±4%
TR(n=11)	6.6±0.8	4.7±0.8	29±6%	6.8±0.6	5.8±0.7	15±4%
P	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001

In summary, a new echocardiographic approach to quantitative evaluation of tricuspid annular size and function is described. Our preliminary findings confirm in man an association between dilatation of the annulus and development of secondary tricuspid regurgitation. This quantitative evaluation may be useful in planning for tricuspid annuloplasty in TR patients undergoing surgery.

THE EVALUATION OF LEFT VENTRICULAR FUNCTION AT REST AND DURING EXERCISE BY TRANSESOPHAGEAL ECHOCARDIOGRAPHY IN AORTIC INSUFFICIENCY

Peter Kremer, M.D., Peter Hanrath, M.D., Burkhard Langenstein, M.D. Masayuki Matsumoto, M.D.; FACC, Carsten Tams, M.D., Walter Bleifeld, M.D., FACC.
Department of Cardiology, University Hospital, Hamburg, W.-Germany

During dynamic exercise transthoracical echocardiography is only of limited value for the evaluation of left ventricular (LV) performance. Therefore we studied LV function during maximal dynamic exercise by supine bicycle ergometry in 8 normal subjects (N) and 12 patients (pts) with symptomatic aortic insufficiency (AI) with transesophageal M-mode echocardiography. With this transesophageal approach where a special transducer is incorporated at the tip of a commercially available gastroscope good continuous recordings of the LV-dimension not disturbed by respiration or thoracical excursion during E were obtained. Systolic blood pressure (BP) measured by cuff and the following echocardiographic indices were determined before (R) and during maximal E: Heart rate (HR), enddiastolic dimension (ED), fractional shortening (FS) and the maximal velocity of fiber shortening (VCF_{max}).

		HR (min^{-1})	BP (mmHg)	ED (mm)	FS (%)	VCF_{max} (sec^{-1})
N	R	85±19	132±14	51± 8	36± 7	2.4±0.4
	E	145±17**	171± 23**	49 ± 9	47± 8**	3.9±0.6**
AI	R	89± 21	152± 22	64±10	35± 6	2.5±0.6
	E	128 ± 24**	176± 27**	62±10	31± 8*	2.3±0.8

± S.D., R vs. E: *p < 0.01, **p < 0.001

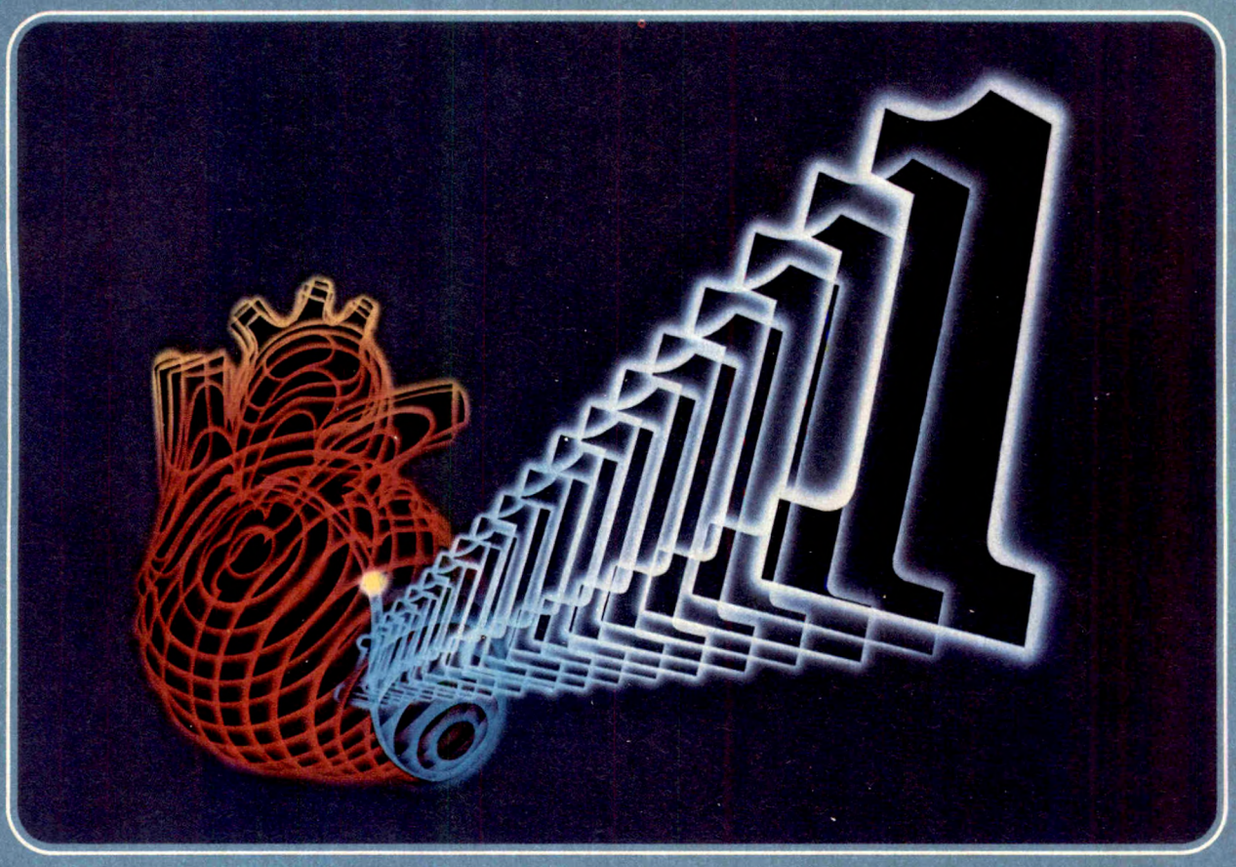
Conclusions: In N and in pts with AI ED was not changed at R and during E. However despite a normal systolic performance at R in AI FS decreased during E unmasking impaired LV systolic function.

QUANTITATION OF AORTIC REGURGITATION WITH TWO-DIMENSIONAL DOPPLER ECHOCARDIOGRAPHY

William J. Bommer, MD, FACC; Randall Mapes, BS; Larry Miller, PhD; Dean T. Mason, MD, FACC; Anthony N. DeMaria, MD, FACC, University of California, Davis, California

Present pulse Doppler (PD) techniques are able to detect the presence but not the severity of aortic regurgitant flow (AR). Therefore we assembled a customized pulse Doppler system to obtain detailed blood flow maps of the left ventricular outflow tract (LVOT) and compared the results with aortography in 25 patients (pts) with suspected AR. The PD system consisted of a two-dimensional (2-D) echo duplex scanner, a modified Doppler detector, a real-time fast Fourier transform (FFT) monitor, and a FFT processor which yielded digital estimators of the spectral spread in Doppler frequency or blood velocity. PD samples for blood flow mapping were obtained by scanning the total area of the left ventricular outflow tract (anterior to the mitral valve (MV) and papillary muscles (PM)) at three levels on 2-D echo short axis (SA) images: Level 1 - just inferior to the aortic valve; Level 2 - at the middle of the MV leaflets; Level 3 - at the PM's. Results showed that disturbed Doppler flow (DDF) was best defined by the digital estimator--median absolute deviation >1000 Hz. DDF was often eccentrically located in the LVOT, however SA mapping of the level and extent of DDF allowed excellent correlation with angiography (0 → 4+); for 8 pts without AR--no DDF was seen at any level (8/8); for 2 pts with 1+ AR--only Level 1 DDF was seen (2/2); for 5 pts with 2+ AR--Level 1 and 2 DDF was seen (5/5); for 5 pts with 3+ AR--Levels 1, 2 and 3 showed DDF (5/5); and for 5 pts with 4+ AR--DDF was seen at Levels 1 and 2, and extended over 50% of the SA area of Level 3 (5/5). Thus PD mapping of the level and extent of DDF allows quantitation of aortic regurgitation and provides valuable noninvasive information in these patients.

CORGARD®
nadolol tablets

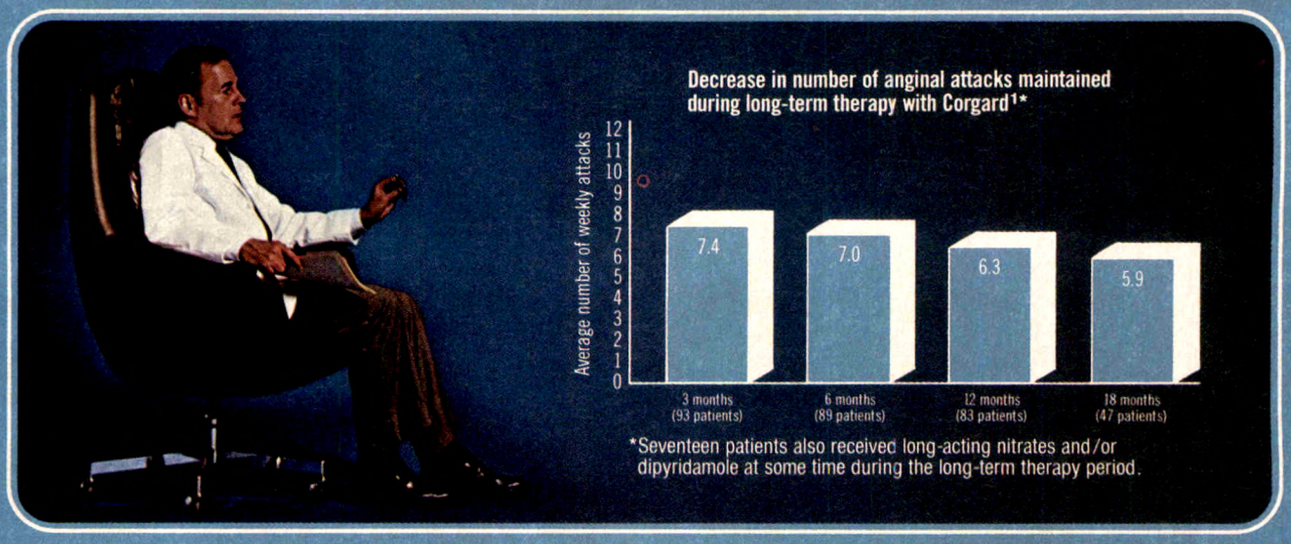


The first and only beta-blocker with once-a-day dosage

In the treatment of angina pectoris

SQUIBB

See last page of this advertisement for brief summary.



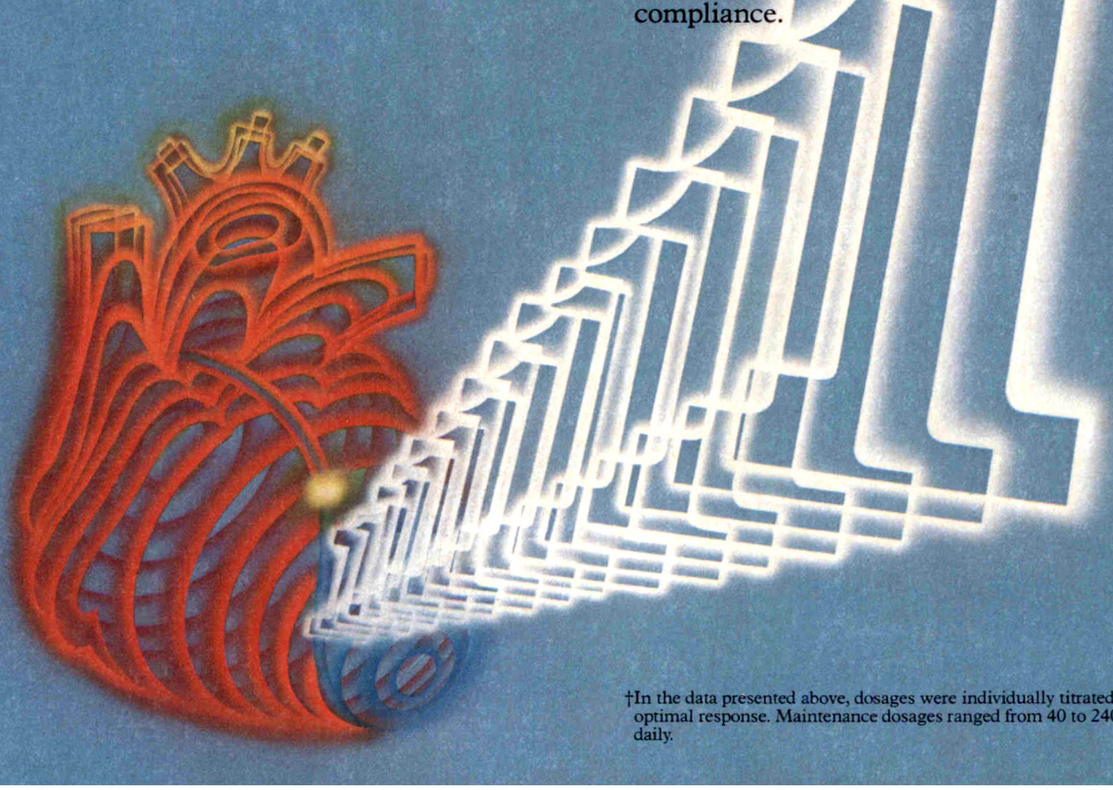
CORGARD® [nadolol tablets]:

Once-a-day, everyday, Corgard offers round-the-clock protection

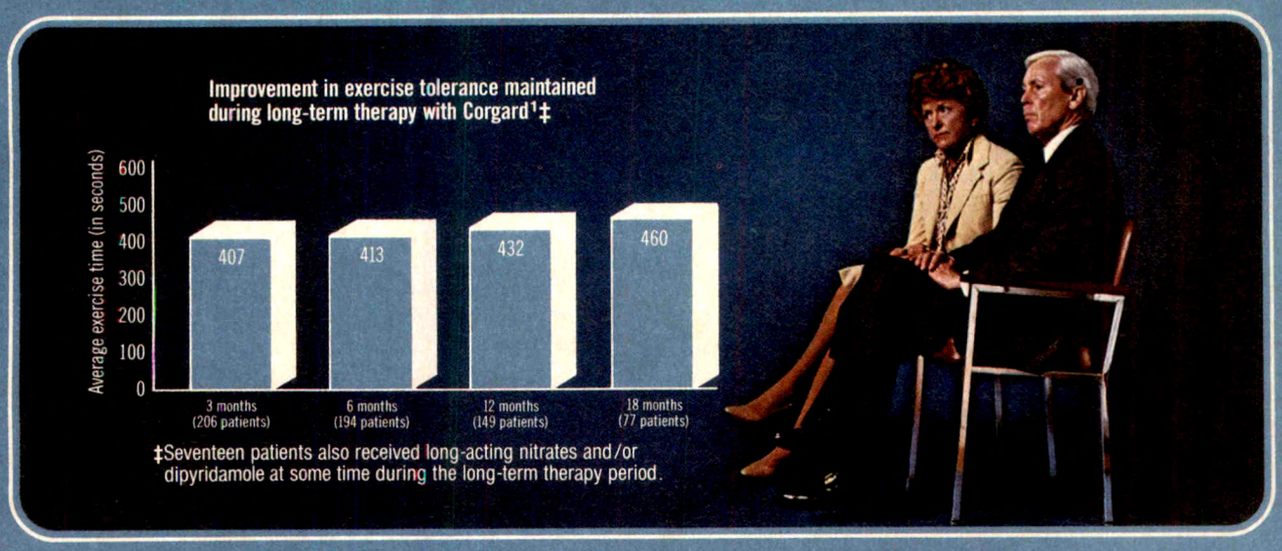
A single daily dose of Corgard offers prophylaxis in angina pectoris, helping to protect the patient all day and all night from painful attacks. And in extended clinical studies, the efficacy of Corgard — as demonstrated by a decreased rate of anginal attacks and an increase in exercise tolerance — was maintained.[1]

Once-a-day, everyday, Corgard decreases the frequency of anginal attacks

Corgard taken just once daily offers round-the-clock protection from angina pain. In one short-term study, Corgard, once a day, decreased the average number of anginal attacks per week in 115 patients with angina, from 13.6 pretherapy to 6.4 at the end of 14 weeks of therapy, a mean decrease of 59%.[1†] In 19% of the 115 patients, anginal attacks were completely eliminated. And the long half-life (20 to 24 hours) makes Corgard the once-a-day beta-blocker, promoting patient compliance.



†In the data presented above, dosages were individually titrated to achieve optimal response. Maintenance dosages ranged from 40 to 240 mg Corgard daily.



Effective control of angina pectoris

Once-a-day, everyday, Corgard increases exercise tolerance

Corgard allows the angina patient to do more. In 147 patients in the same short-term study as the one at left, Corgard, once a day, increased ergometry time by 25%, improving exercise tolerance from an average of 365 seconds pretherapy to 427 seconds at the end of 14 weeks of therapy.[1] In 21% of the 147 patients, the end point of exercise was fatigue rather than angina pain. And the single daily dose of Corgard can be taken at the patient's convenience, without regard to meals.

Once-a-day, everyday, Corgard decreases nitroglycerin usage[1]

Corgard blocks catecholamine influence on myocardial activity, decreases myocardial oxygen demand, and does not have a direct myocardial depressant effect.

40 mg, 80 mg, 120 mg, 160 mg scored tablets

CORGARD® TABLETS
Nadolol Tablets

DESCRIPTION: Corgard (nadolol) is a synthetic nonselective beta-adrenergic receptor blocking agent.

CONTRAINDICATIONS: Bronchial asthma, sinus bradycardia and greater than first degree conduction block, cardiogenic shock, and overt cardiac failure (see WARNINGS).

WARNINGS: Cardiac Failure— Sympathetic stimulation may be a vital component supporting circulatory function in congestive heart failure, and its inhibition by beta-blockade may precipitate more severe failure. Although beta-blockers should be avoided in overt congestive heart failure, if necessary, they can be used with caution in patients with a history of failure who are well-compensated, usually with digitalis and diuretics. Beta-adrenergic blocking agents do not abolish the inotropic action of digitalis on heart muscle. IN PATIENTS WITHOUT A HISTORY OF HEART FAILURE, continued use of beta-blockers can, in some cases, lead to cardiac failure; therefore, at first sign or symptom of heart failure, digitalize and/or give diuretics, and closely observe response, or discontinue nadolol (gradually if possible).

Exacerbation of Ischemic Heart Disease Following Abrupt Withdrawal — Hypersensitivity to catecholamines has been observed in patients withdrawn from beta-blocker therapy; exacerbation of angina and, in some cases, myocardial infarction have occurred after *abrupt* discontinuation of such therapy. When discontinuing chronic use of nadolol, particularly in patients with ischemic heart disease, gradually reduce dosage over a 1- to 2-week period and carefully monitor the patient. Reinstitute nadolol promptly (at least temporarily) and take other measures appropriate for management of unstable angina if angina markedly worsens or acute coronary insufficiency develops. Warn patients not to interrupt or discontinue therapy without physician's advice. Because coronary artery disease is common and may be unrecognized, it may be prudent not to discontinue nadolol therapy abruptly even in patients treated only for hypertension.

Nonallergic Bronchospasm (e.g., chronic bronchitis, emphysema) — PATIENTS WITH BRONCHOSPASTIC DISEASES SHOULD IN GENERAL NOT RECEIVE BETA-BLOCKERS. Administer nadolol with caution since it may block bronchodilation produced by endogenous or exogenous catecholamine stimulation of $beta_2$ receptors.

Major Surgery — Because beta-blockade impairs the ability of the heart to respond to reflex stimuli and may increase risks of general anesthesia and surgical procedures, resulting in protracted hypotension or low cardiac output, it has generally been suggested that such therapy should be withdrawn several days prior to surgery. Recognition of the increased sensitivity to catecholamines of patients recently withdrawn from beta-blocker therapy, however, has made this recommendation controversial. If possible, withdraw beta-blockers well before surgery takes place. In emergency surgery, inform the anesthesiologist that the patient is on beta-blocker therapy. Use of beta-receptor agonists such as isoproterenol, dopamine, dobutamine, or levarterenol can reverse the effects of nadolol. Difficulty in restarting and maintaining the heart beat has also been reported with beta-adrenergic receptor blocking agents.

Diabetes and Hypoglycemia — Beta-adrenergic blockade may prevent the appearance of premonitory signs and symptoms (e.g., tachycardia and blood pressure changes) of acute hypoglycemia. This is especially important with labile diabetics. Beta-blockade also reduces release of insulin in response to hyperglycemia; therefore, it may be necessary to adjust dose of antidiabetic drugs.

Thyrotoxicosis — Beta-adrenergic blockade may mask certain clinical signs (e.g., tachycardia) of hyperthyroidism. To avoid abrupt withdrawal of beta-adrenergic blockade which might precipitate a thyroid storm, carefully manage patients suspected of developing thyrotoxicosis.

PRECAUTIONS: Impaired Hepatic or Renal Function — Use nadolol with caution in presence of either of these conditions (see DOSAGE AND ADMINISTRATION section of package insert).

Information for Patients — Warn patients, especially those with evidence of coronary artery insufficiency, against interruption or discontinuation of nadolol without physician's advice. Although cardiac failure rarely occurs in properly selected patients, advise patients being treated with beta-adrenergic blocking agents to consult physician at first sign or symptom of impending failure.

Drug Interactions — Catecholamine-depleting drugs (e.g., reserpine) may have an additive effect when given with beta-blocking agents. When treating patients with nadolol plus a catecholamine-depleting agent, carefully observe for evidence of hypotension and/or excessive bradycardia which may produce vertigo, syncope, or postural hypotension.

Carcinogenesis, Mutagenesis, Impairment of Fertility — In 1 to 2 years' oral toxicologic studies in mice, rats, and dogs, nadolol did not produce significant toxic effects. In 2-year oral carcinogenic studies in rats and mice, nadolol did not produce neoplastic, preneoplastic, or nonneoplastic pathologic lesions.

Pregnancy — In animal reproduction studies with nadolol, evidence of embryo- and fetotoxicity was found in rabbits (but not in rats or hamsters) at doses 5 to 10 times greater (on a mg/kg basis) than maximum indicated human dose; no teratogenic potential was seen in any of these species. There are no well-controlled studies in pregnant women; therefore, use nadolol in pregnant women only if potential benefit justifies potential risk to the fetus.

Nursing Mothers — It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, exercise caution when nadolol is administered to nursing woman. Animal studies showed that nadolol is found in the milk of lactating rats.

Pediatric Use — Safety and effectiveness in children have not been established.

ADVERSE REACTIONS: Most adverse effects have been mild and transient and have rarely required nadolol withdrawal.

Cardiovascular — Bradycardia with heart rates of less than 60 beats per minute occur commonly, and heart rates below 40 beats per minute and/or symptomatic bradycardia were seen in about 2 of 100 patients. Symptoms of peripheral vascular insufficiency, usually of the Raynaud type, have occurred in approximately 2 of 100 patients. Cardiac failure, hypotension, and rhythm/conduction disturbances have each occurred in about 1 of 100 patients. Single instances of first degree and third degree heart block have been reported; intensification of AV block is a known effect of beta-blockers (see also CONTRAINDICATIONS, WARNINGS, and PRECAUTIONS). **Central Nervous System** — Dizziness or fatigue reported in approximately 2 of 100 patients; paresthesias, sedation, and change in behavior reported in approximately 6 of 1000 patients. **Respiratory** — Bronchospasm reported in approximately 1 of 1000 patients (see CONTRAINDICATIONS and WARNINGS). **Gastrointestinal** — Nausea, diarrhea, abdominal discomfort, constipation, vomiting, indigestion, anorexia, bloating, and flatulence each reported in 1 to 5 of 1000 patients. **Miscellaneous** — Each of the following reported in 1 to 5 of 1000 patients: rash; pruritus; headache; dry mouth, eyes, or skin; impotence or decreased libido; facial swelling; weight gain; slurred speech; cough; nasal stuffiness; sweating; tinnitus; blurred vision. Although relationship to drug usage is not clear, sleep disturbances have been reported. The oculomucocutaneous syndrome associated with practolol has not been reported with nadolol.

Potential Adverse Effects: Although other adverse effects reported with other beta-adrenergic blocking agents have not been reported with nadolol, they should be considered potential adverse effects of nadolol. **Central Nervous System** — reversible mental depression progressing to catatonia; visual disturbances; hallucinations; an acute reversible syndrome characterized by disorientation for time and place; short-term memory loss, emotional lability with slightly clouded sensorium; decreased performance on neuropsychometrics. **Gastrointestinal** — mesenteric arterial thrombosis; ischemic colitis. **Hematologic** — agranulocytosis; thrombocytopenic or nonthrombocytopenic purpura. **Allergic** — fever combined with aching and sore throat; laryngospasm; respiratory distress. **Miscellaneous** — reversible alopecia; Peyronie's disease; erythematous rash.

OVERDOSAGE: Nadolol can be removed from the general circulation by hemodialysis. In addition to gastric lavage, employ the following measures as appropriate. In determining duration of corrective therapy, take note of long duration of effect of nadolol.

Excessive Bradycardia — Administer atropine (0.25 to 1.0 mg). If there is no response to vagal blockade, administer isoproterenol cautiously.

Cardiac Failure — Administer a digitalis glycoside and diuretic. It has been reported that glucagon may also be useful in this situation.

Hypotension — Administer vasopressors, e.g., epinephrine or levarterenol. (There is evidence that epinephrine may be the drug of choice.)

Bronchospasm — Administer a $beta_2$-stimulating agent and/or a theophylline derivative.

DOSAGE: For all patients, DOSAGE MUST BE INDIVIDUALIZED.

For **angina pectoris,** usual initial dose is 40 mg q.d.; gradually increase in 40 to 80 mg increments at 3 to 7 day intervals until optimum clinical response or pronounced slowing of the heart rate; usual maintenance dose is 80 to 240 mg q.d. (most patients respond to mg or less daily). If treatment is to be discontinued, reduce dosage gradually over a period of 1 to 2 weeks (see WARNINGS).

For **hypertension,** usual initial dose is 40 mg q.d.; gradually increase in 40 to 80 mg increments until optimum blood pressure reduction is achieved; usual maintenance dose is 80 to 320 mg q.d. (rarely, doses up to 640 mg may be needed).

Patients with renal failure require adjustment in dosing interval — see package insert for dosage in these patients.

For full prescribing information, consult package insert.

HOW SUPPLIED: In scored tablets containing 40, 80, 120, or 160 mg nadolol per tablet in bottles of 100 and 1000 tablets and in Unimatic® single-dose packs of 100 tablets.

You May Be Mis-Diagnosing Your Holter Patients.

The incompleteness of Holter scan reports with unverifiable numbers and trends are the reasons. Less than 1% of the Holter ECG data is normally presented for your diagnosis.
What happened the other 99% of the time?

1979 brought a breakthrough in Holter monitoring. The development of micro-computer controlled fiberoptics made it possible to print every ECG complex into a textbook format, providing twenty-four, hourly pages of ECG data.

No matter who the operator, the report is identical every time, and only takes three minutes to generate. Plus, this report is faster and easier to read than that of conventional Holter equipment.
The major difference is "Assurance".

The product is The Eliminator™ by AdvanceMed, now a part of American Hospital Supply Corporation. The Eliminator is the first to offer 100% accurate ECG data and is available at half the price of average Holter equipment.

You owe it to yourself and to your patients to see The Eliminator. Since it is compatible with most Holter recording systems, call or write and we'll run one of your tapes.
You May Be Surprised To See What You Are Missing!

American Edwards / AdvanceMed, 1923 SE Main Street, Irvine, California 92714, (714) 751-1824. (800) 854-8081.

ALL THIS WITH ONLY ONE PACER?

- Pace your high threshold cases
- Measure threshold accurately and quickly whenever you want
- Program rapidly without confusion
- Verify the pacer any time by wireless telemetry

Take a look at the Multilith-1® from ELA MEDICAL

Program:
Rate: 30 – 120 ppm
Output: 7.5, 5.0, 2.5 V
Mode: VVI, VVT, VOO
Sensitivity: 1, 2, 3, 4 mV
Refractory period: 310, 470 ms

Features:
High output voltage
Precise threshold test
Simple, sophisticated programmer
Full two-way telemetry

multilith®_1

The practical programmable

EFFICACY OF AFTERLOAD REDUCTION IN AORTIC REGURGITATION: ASSESSMENT BY TWO-DIMENSIONAL ECHO

Martin St. John Sutton, MD, Nathaniel Reichek, MD, Ted Plappert, John A. Kastor, MD, FACC, Hospital of the University of Pennsylvania, Philadelphia, PA

To determine the effects of afterload reduction in the treatment of chronic aortic regurgitation(AR), we developed a method of assessing LV cavity size, wall thickness, and end-systolic wall stress using 2-dimensional echo and systolic cuff blood pressure(P). High-quality echoes of the LV short axis at mitral valve level and simultaneous systolic blood P were obtained in 12 patients with severe AR before and after 0.4 mg sublingual nitroglycerin. LV echograms were digitized to obtain cavity area(CA), and myocardial area(MA) and these results were corrected with a regression equation previously validated in vitro. End-systolic wall stress was calculated as 1.334 x P x CA/MA before and after nitroglycerin(NTG):

	P.(mm)	CA.(cm^2)	MA.(cm^2)	Wall Stress.(dynes/cm^2)
Before: (NTG)	130±20	15.5±9.0	32.2±6.5	79.0±25.8 X 10^3
After: (NTG)	121±17	14.6±8.6	32.1±6.5	69.0±24.8 X 10^3

Nitroglycerin significantly reduced P ($p<.01$), CA ($p<.005$), and end-systolic wall stress ($p<.02$) without any changed in MA or heart rate. In conclusion, we describe a new, reproducible and non-invasive method of assessing end-systolic wall stress, 2) demonstrate that in patients with AR nitroglycerin significantly reduced end-systolic LV size and wall stress, 3) since end-systolic wall stress is the critical factor limiting LV emptying, afterload reduction appears efficacious in the treatment of patients with chronic severe aortic regurgitation.

TWO DIMENSIONAL ECHOCARDIOGRAPHIC EVALUATION OF BRANCH PULMONARY ARTERY STENOSIS

Navin C. Nanda, MD, FACC; Mark S. Rosenzweig, MD; James E. Hodsden, MD; James A. Manning, MD; Shirley Santelli, Univ. of Rochester Medical Center, Rochester, New York

Real time two dimensional echocardiographic studies were performed in 6 patients (ages 5-25 years; 3 females, 3 males) with branch pulmonary artery stenosis proven by cardiac catheterization and angiography. The suprasternal approach was utilized using a commercially available transducer specially suited for this technique. The right pulmonary artery was visualized behind the aortic arch, and angling the transducer leftward brought the main and left pulmonary arteries into view. Discrete narrowing of the lumen at the origin of the left pulmonary artery was seen in one patient with an atrial septal defect, and at the origin of both right and left pulmonary arteries in another patient with tetrology of Fallot and atrial septal defect. Tubular narrowing of the right pulmonary artery was seen in one patient who had pulmonary valvotomy for pulmonary valve stenosis. The main pulmonary artery was large and prominently pulsatile. Tubular narrowing of the right pulmonary artery with post-stenotic dilatation of its distal portion was identified in one patient who had no other cardiac lesions. Diffuse narrowing of both the right and left pulmonary arteries was seen in one patient with mild pulmonary valve stenosis. A large left pulmonary artery with absent right pulmonary artery was identified in one patient with tricuspid atresia. All findings were confirmed at angio-cardiography. Abnormalities of the pulmonary artery branches could not be identified in any patient using the precordial or subcostal approach. Suprasternal two dimensional echocardiographic examination technique is useful in the evaluation of branch pulmonary artery stenosis and this represents a newer extension of the capability of this non-invasive method.

PHOSPHORYLATION OF CARDIAC SARCOPLASMIC RETICULUM (SR) BY A CALCIUM-ACTIVATED, PHOSPHOLIPID-DEPENDENT PROTEIN KINASE.

Constantinos J. Limas, M.D.; University of Minnesota School of Medicine; Minneapolis, Minnesota

A novel cyclic nucleotide-independent protein kinase (PK-C) has been isolated from rat heart cytosol. PK-C can phosphorylate cardiac SR (1.6±0.4 nmol/mg/10 min) in the presence of Ca^{2+} (10^{-7}-10^{-4} M $CaCl_2$) and phospholipids (2-20 µg/ml). Phosphatidylserine is most effective, followed by phosphatidylinositol and phosphatidyl-choline. Diacylglycerols containing unsaturated fatty acids (diolein,dilinolein,diarachidonin) stimulate PK-C by 50-75% by increasing its Ca^{2+} sensitivity. Saturated diacyl-glycerols, mono- and triacylglycerols, on the other hand, are ineffective. PK-C dependent phosphorylation of cardiac SR results in enhanced Ca^{2+} uptake (128±16 nmol Ca^{2+}) mg/min vs 82±9 nmol/mg/min in controls, $p<0.01$)and Ca^{2+} ATPase activity (63±7 nmol P_i/mg/min vs 46± 5 nmol/mg/min, $p<0.01$). PK-C may, therefore, be an important determinant of cardiac SR function by serving as a link between calcium fluxes and membrane glycerolipid metabolism. Stimulation of Ca^{2+} transport by cardiac SR is amplified by the increased Ca^{2+} sensitivity of PK-C mediated through unsaturated diacylglycerols.

METABOLISM OF ARRHYTHMOGENIC LYSOPHOSPHATIDES IN RABBIT MYOCARDIUM

Richard W. Gross, MD; Burton E. Sobel, MD, FACC, Washington University, St. Louis, Missouri

Cardiac metabolism of lysophosphatidyl choline (LPC), implicated as a mediator of dysrhythmia induced by ischemia, has not been elucidated. To determine whether LPC transacylase acitivity, analogous to that in liver, is present in heart muscle, rabbit heart extracts were prepared by mincing; homogenization in 0.25 M sucrose (25% w/v), 1 mM DTT, 10 mM phosphate, pH 7.4; and centrifugation at 3,000, 8,000, 20,000 g for 10 min and 100,000 g for 1 hr. LPC-transacylase in the supernate was assayed in 800 µl of media containing 75 mM buffer, pH 5 to 9; 3 mM MgCl; 120 µM 1-^{14}C-LPC; and 600 µg protein incubated at 37° for 15 min; products extracted in 750 µl butanol and separated by HPLC; and radioactivity quantified. Transacylation, manifested as synthesis of 1,2-^{14}C-phosphatidylcholine (PC) occurred at a high rate (0.61 ± .07 (SE) nmols/mg protein/min (n = 6), displayed a sharp pH optimum at pH 7.0, and was linear with respect to incubation time and protein concentration. To identify the position of incorporated label, PC synthesized was isolated by HPLC and treated with snake venom phospholipase A_2. The ratio of labeled fatty acid to labeled LPC was 1.09 ± .11 (n = 4), demonstrating the initial presence of PC labeled in both the 1- and 2-positions. To detect other reactions such as direct acylation (LPC acyl transferase), cytosol was incubated under the same conditions with ^{14}C-palmitoyl CoA and unlabeled LPC. PC synthesis was < 10% of that seen with labeled LPC. Thus, rabbit heart cytosolic extracts exhibit considerable LPC transacylase activity (but not LPC acyl transferase) that does not require acyl CoA and that appears to contribute substantially to LPC metabolism.

FLOW-INDEPENDENT CHARACTERISTICS OF EXTERNALLY DETECTABLE CARDIAC KINETICS OF ^{11}C-PALMITATE

Steven R. Bergmann, PhD; Rene A. Lerch, MD; Burton E. Sobel, MD, FACC, Washington University, St. Louis, Missouri

It has been suggested that flow-dependence of ^{11}C-palmitate kinetics precludes their use as an externally detectable measure of metabolism. To differentiate the independent effects of the two types of determinants, 15 isolated, paced, isovolumically beating rabbit hearts were perfused retrograde at constant flow at 37° with washed sheep erythrocytes in a modified Krebs-Henseleit buffer containing 0.4 mM albumin and equimolar palmitate. This preparation permits maintenance of flow within the physiological range. Myocardial time-acitivity curves, monitored in the coincidence mode for 20 min after aortic injection of 50 μCi of albumin-bound ^{11}C-palmitate, exhibited three distinct monoexponential phases, the first representing vascular transit. Deconvolution techniques indicated incorporation of 20.8 ± 1.9 (SE)% of tracer into a pool with a turnover rate constant (k) of 1.4 ± 0.6 x 10^{-3}min^{-1} ($t_{1/2}$ = 2.0 ± .2 min) and 15.0 ± 1.0% into a second pool with a k of .25 ± .05 x 10^{-3}min^{-1} ($t_{1/2}$ = 48.4 ± 10.6 min). Administration of 4.1 x 10^{-7}M epinephrine increased cardiac work and MVO_2 by 60%. Although flow was held constant, extraction of tracer into the first pool increased significantly ($p < .01$) to 89.2% without an increased turnover rate while turnover rate of the second pool increased markedly (k = 0.38 ± 0.04 x 10^{-3}min^{-1}, $t_{1/2}$ = 32 ± 3.2 min, $p < .01$ vs control). Thus, changes in fatty acid metabolism are readily detectable externally with ^{11}C-palmitate despite maintenance of constant flow, and should permit non-invasive quantitation of cardiac fatty acid utilization.

KINETICS OF C-11 LABELED PALMITATE IN ISCHEMIC MYOCARDIUM

H.R. Schön, MD; J.R. Robinson, PhD; H.R. Schelbert, MD; J.R. Barrio, PhD, UCLA School of Medicine, Los Angeles, CA

For future studies using positron emission computed tomography, single pass extraction fraction (E) and halftimes (T) of C-11 palmitate (CPA) in ischemic myocardium and their relationship to myocardial blood flow (MBF), oxygen consumption (MV) and myocardial CO_2 production were determined in 13 experiments in 7 open chest dogs. Following stenosis of the left anterior descending coronary artery and intracoronary injection of CPA, E and T of CPA were determined from the peak and slope of the myocardial time activity curve recorded with a scintillation probe for 60 minutes. The curve consisted of a vascular phase, an early rapid (R) and a slow phase (S). T of R increased with reduced MBF (T=13.46-0.11 MBF, r=0.74) and reduced MVO (T=13.77-0.74 MVO, r=0.83), while T of S was not influenced by MBF and MVO. Peak C-11 CO_2 production of ischemic myocardium, determined from MBF and the arteriovenous C-11 CO_2 difference, fell with decreased MBF by y=1503 exp (0.04 MBF), r=0.85. T of C-11 CO_2 production correlated with T of R (y=0.21+0.89x, r=0.98). The ratio of peak C-11 CO_2 production and peak CPA washout averaged 1.59±.14 and fell with decreased MBF (r=0.81). E averaged .60±0.09 and did not change significantly with altered MBF and MVO. E of R (ER) fell with decreased MBF (ER=1.77+0.16 MBF, r=0.70) and MVO (ER=12.33+1.22 MVO, r=.73), whereas E of S (ES) increased with decreased MBF (ES=57.70-2.34 MVO, r=0.79). The ratio of E for R and S fell with decreased MBF (ER/ES=-0.05+0.12 MBF, r=0.80) and MVO (ER/ES=0.005+0.08 MVO, r=0.83).

In ischemic myocardium CPA is present in two pools, R being characterized by ß-oxidation and washout of CPA, S mainly by storage of CPA. With increasing ischemia rate and extent of ß-oxidation decreases whereas storage of CPA increases.

LEFT VENTRICULAR CONTRACTILE FAILURE FOLLOWING HYPOTHERMIC ISCHEMIC ARREST: PROTECTION BY CORONARY ARTERY WASHOUT.

Joseph T. Walls, MD; Fred Nasser, MD; David W. Baron, MD; John H. Tinker, MD; Carlos E. Harrison, MD, FACC, Mayo Foundation, Rochester, MN.

This study was undertaken to assess the value of multidose coronary artery washout (MCW) independent of cardioplegic arrest or profound hypothermia. Dogs (10±1 kg) were studied during cardiopulmonary bypass (28°C) and either 60 min (hemodynamic function, n=11) or 120 min (biochemical function, n=11) anoxic arrest. Dynamic normothermic LV function curves were generated while on right heart bypass immediately prior to anoxic arrest, and after 60 min reperfusion. Control dogs underwent simple ischemic arrest. MCW dogs had 200 ml initial (50 mm Hg, 100 ml/min, 28°C) buffered saline (pH 7.4) infused into the aortic root at cross-clamping, then 50 ml each 15 min. Results tabulated show significantly better ATP, ATP/ADP ratio, lactate concentrations at 120 mins anoxia and superior LVSW following 60 mins reperfusion. These data suggest that removal of anaerobic metabolites preserves LV contractile function following anoxic arrest independent of hypothermia.

Anoxia 28°C	120 mins. ATP (µM/g)	ATP/ADP	Lactate (µM/g)	60 mins. LVSW (g-meters)	LVEDP (mm Hg)
Control	1.67±0.16	1.84±0.15	35.6±0.6	1.2±0.05	21.8±3.5
MCW	2.19±0.13*	2.81±0.19#	19.9±2.7@	26.3±7.7+	7.6±0.4

REVERSIBILITY OF DIABETIC CARDIOMYOPATHY WITH INSULIN IN RATS

Frederick Fein, MD, FACC; Ashwani Malhotra, PhD; John E. Strobeck, MD, PhD; Joseph M. Capasso, PhD; James Scheuer, MD, FACC; Edmund H. Sonnenblick, MD, FACC, Albert Einstein College of Medicine, Bronx, New York

Streptozotocin (Sz) induced diabetes (D) in Wistar rats causes a depressed force-velocity relation and slowed relaxation in isolated left ventricular papillary muscle. Actomyosin (AM) ATPase activity is also lower in D rats. The effects of insulin (4-5 units SQ/day) on these parameters were observed. Rats made D with Sz were treated 6-9 weeks later for 10 days (D+I) and compared with untreated D and controls (C). Three D rats, treated for 2 days, had normal [Glu] but all other values unchanged from D rats.

	C(n=13)	D(12)	D+I(13)
[Glu] mg%	140±5[1,2]	643±22	61±9[2]
Body wt (g)	242±4(12)[2]	197±5	242±3[2]
Heart wt (g)	.63±.01[2]	.57±.01	.73±.01[2]
DT (g/mm)[3]	4.95±.64[4]	5.81±.55	5.73±.48[4]
T1/2R (msec)[4]	101±4[2]	144±7	108±4[2]
Vs	.79±.03[2]	.63±.03	.77±.03[2]
AM ATPase[6]	.618±.007(8)[2]	.253±.015(8)	.525±.024(8)[2]

[1]Mean ± SEM, [2]p < .05 (comparison with D), [3]Max isometric [5]developed tension, [4]Time from DT to fall to 1/2 DT, [5]Peak shortening velocity at total load 45% of total isometric tension (lengths/sec), [6]µmoles Pi/mg protein/min.

These results indicate that the cardiac abnormalities induced by Sz diabetes in the rat are largely reversible with insulin.

EXERCISE PHYSIOLOGY AND TESTING
8:30-10:00

PROGNOSIS OF PATIENTS WITH CORONARY ARTERY DISEASE BY EXERCISE TESTING

Donald A. Weiner, MD, FACC; Carolyn H. McCabe, BS; Sally S. Cutler, BS; Thomas J. Ryan, MD, FACC, Boston University Medical Center, Boston, MA

To assess whether exercise testing could help predict cardiac mortality, we analyzed 14 exercise and 10 clinical variables in 292 patients treated medically, who underwent treadmill exercise testing and cardiac catheterization. All patients were followed annually for up to 4 years. There were 13 cardiac deaths (4.5%). By multivariate discriminant analysis, the most important prognostic variables were: treadmill time, duration of ST depression, peak systolic blood pressure and cardiac enlargement. Although many of the individual clinical and exercise variables analyzed were frequently abnormal in those patients who died (sensitivity range 46% to 92%), none could accurately predict cardiac mortality (predictive value range 10-30%).

Combinations of variables were then analyzed in the subset of patients with multivessel coronary disease (n=113) whose total cardiac mortality was 11%. A high risk subgroup (n=59) consisting of patients with either severe exercise ischemia ($\geq$ 2mm ST depression lasting $\geq$ 5 minutes involving $\geq$ 3 leads) or left ventricular dysfunction (treadmill time $\leq$ 3 minutes or cardiac enlargement) had a mortality of 19% (11/59); this was significantly greater ($p < 0.01$) than a low risk subgroup (n=54) with neither severe exercise ischemia nor left ventricular dysfunction whose mortality was 2% (1/54).

We conclude that combining clinical and exercise variables to distinguish high and low risk subgroups of patients with similar coronary anatomy is useful in predicting cardiac mortality.

ERRORS OF ESTIMATION OF FUNCTIONAL CAPACITY IN CARDIAC PATIENTS

Henry S. Miller, Jr., MD, FACC; Kenneth S. Jago, MA; Paul M. Ribisl, PhD; W. Thomas Boone, PhD, Bowman Gray School of Medicine, Winston-Salem, NC

It is common practice to use standard tables in estimating the maximal functional capacity of patients from the results of a graded exercise test. The estimated values are based upon the oxygen requirement of the task while measured values, using standard gas analysis methods, reflect the oxygen delivered. To determine whether significant differences exist between estimated and observed values, 230 cardiac patients were measured on oxygen uptake during a graded exercise test on a treadmill which started at 1.7 METs and increased by 1.0 METs every second minute until a symptom-limited endpoint was reached. It was found that significant ($P < 0.05$) differences occurred at all stages above 5 METs and the disparity widened with further increments in workload. When the sample was divided into four separate groups by diagnosis (anterior myocardial infarction, inferior myocardial infarction, coronary artery bypass surgery and other) no significant ($P > 0.05$) differences among groups were observed. Similarly, three different criteria for test termination (fatigue, ECG changes or angina pectoris) failed to reveal any significant differences among groups. In conclusion, the use of standard tables overestimate the measured functional capacity of cardiac patients by 18 to 33 percent at workloads requiring from 5 to 8 METs, respectively. A regression line was developed which accurately estimates the true measured values with a standard error of $\pm$ 0.12 METs. It is recommended that the standard tables be appropriately adjusted to improve the safety and accuracy of prescription in cardiac patients for vocational and/or recreational activities.

EFFECT OF RATE-DEPENDENT LEFT BUNDLE BRANCH BLOCK ON LEFT VENTRICULAR EJECTION FRACTION AND REGIONAL WALL MOTION

Dean A. Bramlet, MD, Kenneth G. Morris, MD, David Albert, AB, R. Edward Coleman, MD, Frederick R. Cobb, MD, Duke University and VA Medical Centers, Durham, N.C.

The effect of rate-dependent left bundle branch block(RD LBBB) on LV function is unknown. To determine prospectively the independent effect of RDLBBB on LV ejection fraction(EF) and regional wall motion(WM), 6 patients with RDLBBB were selected on the basis of normal coronary arteriograms or normal thallium scintigrams obtained at maximum heart rates. The critical heart rates for developing RDLBBB were determined by preliminary upright bicycle exercise. Multigated radionuclide angiograms in the left anterior oblique view then were obtained during a second exercise. Serial measurements of LV function were made at rest, immediately before and after onset of RDLBBB, and at peak exercise. Regional WM was determined for 6 LV wall segments(2 inferoapical, 2 posterolateral, 2 septal) for each acquisition. The critical heart rate(HR) for developing RDLBBB was 113±23 beats/min (mean ± SD) which averaged 30 beats/min below peak heart rate. Mean(± SD) responses in EF and HR were as follows:

	Rest	Pre LBBB	Post LBBB	Peak
HR	77±10	108±20	114±21	145±14
EF	64±10	68±7	61±7	67±11

Regional WM in each case was normal preceding RDLBBB. With onset of RDLBBB each patient developed LV asynchrony with delayed apical contraction. Hypokinesia developed in 7 LV segments(5 inferoapical, 1 posterolateral, 1 septal) in 4 patients (66%).

Conclusion: in normal subjects during exercise the development of RDLBBB results in an abrupt decrease in LVEF, asynchronous LV contraction, and often regional areas of hypokinesia. A small overall increase in LVEF occurs despite development of RDLBBB if exercise is carried to peak levels.

EFFECT OF ANTIHYPERTENSIVE MEDICATIONS ON PHYSICAL WORK CAPACITY

Richard S. Crow, MD; George Sopko, MD; David R. Jacobs, PhD; Henry L. Taylor, PhD; Robert Serfass, PhD; University of Minnesota, Minneapolis, MN.

Cardiopulmonary fitness (MVO_2) is routinely estimated from submaximal work pulse rate (HR). Propranolol is known to reduce exercise HR and invalidates regression estimates of MVO_2. This study examines the influence of 4 additional antihypertensive medications (M) on MVO_2 prediction by measuring oxygen uptake (VO_2) and HR during submaximal and maximal exercise testing of 20 non-hypertensive males aged 20-30. Five M treatments assigned by double blind randomization were: 1) Hydrochlorothiazide (H) 50 mgs/d; 2) H + Aldomet 10 mgs/kg/d; 3) Chlorthalidone 50 mgs/d + Reserpine 0.1 mgs/d; 4) Hydropres one/d + Hydralazine 0.50 mgs/kg/d and 5) Placebo (P). We exercise tested all men in a baseline period (BL), 2 weeks on M and 3 weeks post (PM). Results: All men completed study. M adherence was 99%. No M was associated with a statistically significant decrease in rest diastolic blood pressure when compared with P, but M 2 and 3 were associated with a statistically significant decreased exercise systolic blood pressure compared with P (-19 and -22.5 mmHg). Two-way analysis of variance, allowing for a period and drug effect, showed no statistically significant effect on MVO_2 ml/kg/min. or regression estimates of Δ HR at fixed VO_2 for any M compared with P adjusted for BL response (maximum Δ HR was -7, SE diff. 5.4). We conclude from these data short-term M administration does not confound estimates of MVO_2 from submaximal HR. Further confidence in M induced Δ HR could be gained by larger sample, e.g. 85 is the estimated number of men needed to establish the significance of the observed $\pm$ 7 Δ HR at α = .05 and β = 85%.

DIGITALIS AND EXERCISE TESTING, A FIVE YEAR FOLLOWUP.
M.H. Sketch, F.A.C.C., S.M. Mohiuddin, F.A.C.C., A.Mooss, F.A.C.C., and C.K. Nair, Omaha, Nebraska

To evaluate the influence of digitalis on the results of exercise testing and the prognostic significance of digitalis induced false positive tests, 98 healthy men, 22-70 years, were studied. All had normal initial exercise tests. All took digoxin 0.25mg daily for 14 days. Subsequently, repeat daily exercise tests were performed until a negative test was obtained. Five years later, 76 men had a repeat exercise test. Medical history was obtained from 92 subjects. Six were lost to follow-up. Twenty five percent of men (24 of 98) had digitalis induced positive tests. There was a direct relationship between age and the incidence of falsely positive tests ($P=<0.03$). The incidence over age 60 years was 100% (5 of 5). Digitalis blood levels did not correlate with positive tests. The maximum ST depression induced by digitalis and exercise was 1.9mm. No test remained positive more than 12 days after discontinuing digitalis. No men developed symptomatic ischemic heart disease. Five had borderline or positive exercise tests at followup. Four of these had had digitalis induced positive tests initially.

It is concluded: 1) Patients receiving digitalis are likely to have false positive exercise induced changes especially over age 60 years. 2) Twelve days after discontinuing digoxin, results of exercise testing can be relied upon. 3) In the absence of heart disease, digoxin induces only moderate ST depression. 4) A positive test induced by digitalis does not predict subsequent 5 year morbidity and mortality. 5) The incidence of digitalis induced false positive exercise tests correlates directly with age and abnormal tests at followup. Hence, digitalis may "unmask" an age related pathology eg. coronary artery stenosis.

EFFECT OF DOPAMINE AND DOBUTAMINE ON REGIONAL BLOOD FLOW, MYOCARDIAL OXYGEN CONSUMPTION AND HIGH ENERGY PHOSPHATE COMPOUNDS DURING CARDIO-PULMONARY BYPASS
Stanley Einzig, MD; John E. Foker, MD; Herbert B. Ward, MD; Richard W. Bianco, Barbara Borgwardt, Tingchung Wang, PhD; University of Minnesota, Minneapolis, Minnesota

Catecholamines are clinically important in the treatment of low CO following cardiopulmonary bypass (CPB), but questions remain on the net consequences for the stressed myocardium and the circulation. Dogs were placed on CPB, subjected to 20 min of warm global ischemia and supported for 20 min on CPB. Either 10 ug/kg/min of dopamine (Dp) or dobutamine (Db) was used as a continuous infusion for 10 min to wean the dogs from CPB and support them for 60 min off CPB. Regional blood flow (BF)(15 um radio-labeled spheres), myocardial oxygen consumption (MVO_2) and high energy phosphate levels were measured 5 min prior to coming off CPB and 60 min off CPB. Both drugs promptly altered tissue BF patterns without changing pump flow and gave the following results on CPB:

	MVO_2 (ml/min/g)	LVBF (ml/min/g)	LV Endo/Epi Ratio	Renal BF (ml/min/g)
Control (n=7)	0.03±0.02	0.62±0.05	0.94±0.04	5.56±0.32
Dopamine (n=9)	0.19±0.02	1.50±0.17	0.94±0.04	5.16±0.41
Dobutamine (n=8)	0.15±0.03	2.06±0.36	0.82±0.06	2.55±0.48

Both drugs, as expected, increased MVO_2, left ventricular BF and cerebral BF, but renal BF fell with Db. Post CPB, CO with Dp (94±5 ml/min/kg) or Db (148±15 ml/min/kg) exceeded control (66±7 ml/min/kg), cerebral and renal BF equalled control levels, and MVO_2 remained elevated. The changes in high energy phosphate levels were similar to control during and following CPB. In summary, (1) both drugs increased myocardial BF, indicating oxygen supply was meeting the increased demand, and suggesting benefit in coming off CPB; (2) on CPB, Db reduced renal BF; (3) off CPB both drugs were effective in increasing CO and maintaining renal BF, while meeting myocardial oxygen demand.

EFFECT OF VERAPAMIL ON EXERCISE-INDUCED REGIONAL MYOCARDIAL DYSFUNCTION IN CONSCIOUS DOGS.
Genta Osakada,MD; Toshiaki Kumada,MD; Kim P. Gallagher, Ph.D; W.Scott Kemper, MSEE; John Ross, Jr., MD, FACC. Univ. of California, San Diego, La Jolla, California.

The effect of verapamil (V) on exercise-induced myocardial dysfunction was evaluated in 9 conscious dogs in which ultrasonic crystals were placed for measuring wall thickness (WTh) in control (C) and ischemic(I) regions. An ameroid constrictor and an ultrasonic doppler flow probe were positioned on the circumflex coronary artery (CCA). At 23 days (average) postoperatively, complete cessation of CCA flow was confirmed by the flowmeter. Treadmill exercise was then performed for 3.8 min. at a speed of 7.5 MPH and grade of 5.3% (average), and two hours later the same exercise bout was repeated after verapamil (160 mg, P.O.):

	Before V		After V	
	Rest	Run	Rest	Run
Heart rate (beats/min)	101	243**	114	221**#
LV systolic pressure(mmHg)	130	166**	127	168**
CWTh End-diastole (mm)	10.0	10.3	10.1#	10.3
% thickening	22.4	23.8	22.1	25.7
IWTh End-diastole (mm)	10.0	10.3*	10.3#	10.6
% thickening	19.6	5.9**	17.6#	11.5**##

% thickening: percent wall thickening during systole.
*P<0.05,**<0.01: comparison between rest and running.
#P<0.05,##<0.01: comparison, before and after V.

During control running, severe regional dysfunction was observed in I zone (average % decrease in systolic WThickening = 73±7%, SEM). After V, regional dysfunction during running was markedly improved (% decrease in WThickening = 34±12%). Thus verapamil lessened exercise-induced ischemia in the collateral dependent bed, an effect which may relate to decreased heart rate and O_2 demand, improved collateral blood flow, or both.

ENHANCED MYOCARDIAL PRESERVATION IN ANIMALS AND MAN WITH NIFEDIPINE AND CARDIOPLEGIA
Richard E. Clark, MD, FACC, Ignacio Y. Christlieb, MD, Thomas B. Ferguson, MD,FACC, Clarence S. Weldon, MD, FACC, and Burton E. Sobel, MD, FACC, Washington University, St. Louis, Mo.

To characterize efficacy of a clinical cardioplegic solution (CPS) supplemented with a calcium antagonist, nifedipine (N), 30 dogs subjected to 1, 2, and 3 hrs of hypothermic (18°) global ischemia (I), were treated with aortic root bolus injection (q 30 min) of N in CPS, CPS alone or Ringer's (R). CPS + N preserved normal volume loading responses 2 hr post I and resulted in normal stroke work index(SWI) of 19 ± 2 gm·m/m^2 vs. CPS (14 ± 2) $p<0.05$ or vs. R of 10 ± 3 ($p<0.01$) at similar preloads and rates. Other indices of preserved functional and structural integrity: LVEDP, LVdP/dt, cardiac output, and histology were concordant. Subsequently, N in CPS was given to 26 Class III or IV patients (pts) (ave. age= 58 yr, 17 males) requiring an ave. of 109 min of I during bypass for single or multiple, initial or repeat valve replacement (13), CABG (7) and valve and CABG (6). Mortality by cause was comprised of uncontrollable intraoperative hemorrhage (2), late hemorrhage (1), and respirator failure (1). There were no deaths from LV failure. In contrast, a 42% incidence of postop LV power failure occurred in 31 comparable pts with similar preop ventricular function (EF <30%, CHF 82%) treated with CPS alone with a LV power failure mortality rate of 15%. Thus, nifedipine is an effective adjunct to CPS which enhances myocardial preservation in poor risk patients with complex lesions requiring extended ischemic times. Use of nifedipine has resulted in a decreased mortality and incidence of IABP support.

MECHANISM OF ACTION OF THE ENCIRCLING ENDOCARDIAL VENTRICULOTOMY (EEV) FOR TREATMENT OF INTRACTABLE ISCHEMIC VENTRICULAR TACHYCARDIA.

Ross M. Ungerleider, MD; Gary K. Lofland, MD; J. Mark Williams, MD; T.E. Stanley, BA; Raymond E. Ideker, MD, PhD; William H. Smith, PhD; James L. Cox, MD, Duke University Medical Center, Durham, North Carolina 27710.

The Encircling Endocardial Ventriculotomy (EEV) has been applied in over 50 patients for the treatment of intractable ischemic ventricular tachycardia and has been successful in 100% of survivors (operative mortality=15%). Previous studies from our laboratory have demonstrated that the EEV may isolate ventricular tachycardia from the remainder of the heart, but more often it ablates the region from which the reentry circuit originates. The purpose of this study was to clarify the relationship between the electrophysiologic and regional myocardial blood flow (RMBF) alterations induced by the EEV. Twenty-eight dogs underwent an EEV while on cardiopulmonary bypass. Bipolar and unipolar data were recorded from epicardial plaque and intramural plunge electrodes and were correlated with RMBF using radioactive tracer microspheres. The subendocardium within the EEV demonstrated a 60-70% decrease in blood flow (vs. control) and acute loss of all local electrical activity in 41.6% (20/48) of subendocardial electrograms. Outside the EEV, RMBF increased and normal local electrical activity persisted in all intramural electrograms(102/102) Within the EEV, the diastolic pacing threshold was increased from 0.31±0.03 mA before the EEV to 0.89±0.19 mA after the EEV ($p<0.002$). Pacing thresholds outside the EEV were unchanged by the surgery. These data suggest that the EEV ablates reentrant ventricular tachycardia by making the encompassed myocardium more uniformly ischemic, thereby altering the local anatomic-electrophysiologic substrate such that reentry circuits can no longer be maintained.

THE COMPARATIVE EFFECTS OF INTERMITTENT ISCHEMIC ARREST AND POTASSIUM CARDIOPLEGIA ON DIASTOLIC VENTRICULAR COMPLIANCE IN PATIENTS

W. Randolph Chitwood, Jr., MD; Ronald C. Hill, MD; James D. Sink, MD; Craig O. Olsen, MD; Andrew S. Wechsler, MD, Duke and Veterans Administration Medical Centers, Durham, North Carolina 27710

Left ventricular diastolic properties were examined in 24 patients undergoing coronary grafting using either 32°C intermittent ischemia (IA) or 4°C potassium cardioplegia (CP). Patient groups had similar ages, cardiac function, and number of grafts. For compliance data, hearts were filled passively during bypass perfusion to diastolic pressures (P) between 0 and 20 mmHg while minor axis dimensions were measured by epicardial ultrasonic crystals. End-diastolic lengths (EDL), normalized to a Lagrangian strain definition (ε), were compared by the non-linear equation, $P=\alpha(e^{\beta\varepsilon}-1)$. Both elastic constants, α and β, as well as linear regression slopes (k) of P-ε data were compared as indices of ventricular stiffness. Prior to determinations, the EDL at 0 mmHg P was defined as ℓ_o. Mean data are shown as ε at specific filling P:

*p < .01

N=12	ℓ_o(mm)	ε5	ε10	ε15	ε20	k
Pre IA	52.5	.067	.121	.142	.163	8.2
Post IA	53.0	*.049	*.083	*.098	*.116	*11.4
N=12						
Pre CP	48.0	.048	.091	.115	.140	7.9
Post CP	48.0	.037	.090	.115	.132	9.1

In these patients α, β, and k were altered by IA but not CP. Therefore, stiffening did not occur with CP despite ischemic durations twice those of IA. These data confirm CP to be a superior method of cardiac protection during coronary bypass procedures and show diastolic ventricular properties to be a sensitive indicator of subclinical ischemic injury.

INCREASE IN REGIONAL MYOCARDIAL PERFUSION POST-CORONARY ARTERY BYPASS GRAFTING.

Steven Goldman, MD, FACC; Robert Henry, MD; Mark J. Friedman, MD, FACC; Theron Ovitt, MD; Alan Rosenfeld, MD; Neal Salomon, MD; Jack Copeland, MD. Tucson VA Medical Center and University of Arizona, Tucson Arizona.

The objective of coronary artery bypass grafting (CABG) is to increase blood flow to ischemic areas of the myocardium. To determine if this was achieved, anterior wall myocardial perfusion was measured at rest and during intracoronary papaverine (5 mg), utilizing Xenon-133 washout in 35 patients (pts). Twelve control pts had no significant diameter narrowing (0-25%) of the left anterior descending coronary artery (LAD), 13 pts had >50% narrowing of the LAD, and 10 pts had >50% narrowing of the LAD with patent saphenous vein bypass grafts to the LAD and were studied 11.3±3.1 months post CABG. There was no significant difference in age, LVEDP, global ejection fraction (EF) or segmental area EF between the patients except that the controls had an increased antero-basal area EF compared to the other pts. There was no significant difference in anterior wall myocardial perfusion at rest between controls (61.0±3.7 ml/min/100g) and unoperated LAD pts (60.2 ±5.4 ml/min/100g), or operated LAD pts (63.4±4.8 ml/min/100g). During coronary arteriolar vasodilatation with papaverine, anterior wall perfusion increased in the operated pts to 140.6±6.8 ml/min/100g. This was significantly greater ($p<.001$) than the increase in the unoperated LAD pts (72.8±8.1 ml/min/100g) but not different than the increase in the controls (145.3±8.4 ml/min/100g). These data indicate that in pts with coronary disease, increases in myocardial perfusion are limited by the resistance of the proximal stenosis independent of vasodilatation distal to the stenosis. After successful CABG, the patent vein graft restores control of myocardial perfusion to the arteriolar bed.

COMPARISON OF TECHNIQUES FOR INTRAAORTIC BALLOON INSERTION

Charles E. Bemis, MD, FACC, Eldred D. Mundth, MD, FACC, Gary S. Mintz, MD, FACC, A-Hamid Hakki, MD, Abdulmassih S. Iskandrian, MD, FACC, Demetrios Kimbiris, MD, FACC, Inder Goel, MD, Margaret Riddle, RN. Cardiovascular Institute, Hahnemann Medical College and Hospital, Philadelphia, PA.

Percutaneous insertion of (Datascope) intraaortic balloon (IAB) was attempted in 44 patients (pts) between January and August 1980. The indications were: unstable angina (26 pts), severe LV dysfunction (6 pts), acute ventricular septal defect or mitral regurgitation (4 pts), and postoperative low CO (8 pts). Successful insertion was rapid, less than 15 minutes in 40 pts (91%) and was performed at bedside in 31 pts (70%). Unsuccessful attempts in 4 pts (9%) occurred in our earlier experience (4 of the first 15 pts). The use of the long (16") sheath instead of the regular sheath (7") has obviated the occasional difficulty in maneuvering the stiff IAB beyond the aortic bifurcation. Pts were not excluded because of claudication if a femoral pulse was present. The duration of counterpulsation was 1 to 9 days. After removal, hemostasis was obtained with firm pressure for 10-30 min. Two pts (5%) developed thrombosis of the femoral artery and required embolectomy; there were no other complications. Satisfactory augmentation was accomplished in all successful insertions. Doppler pedal pressures were measured in 10 pts and were unchanged after IAB. In the previous 18 months IAB insertion, via arteriotomy, was attempted in 95 pts with 15 failures (16%). There were 18 complications (19%) including limb ischemia, infection and delayed wound healing. We conclude: percutaneous IAB insertion (1) can be performed quickly at the bedside, (2) has a high success rate particularly with the long sheath, (3) has a lower rate of complications ($p < .01$), (4) does not require the surgical expertise to perform a femoral arteriotomy. The percutaneous route is the method of choice for IAB insertion.

ACUTE MYOCARDIAL INFARCTION: I. ASSESSMENT OF ACUTE PHASE; II. ASSESSMENT IN CHRONIC PHASE
8:30-10:30

VASCULAR DETERMINANTS OF EARLY RECURRENT MYOCARDIAL INFARCTION

Alon Marmor, MD; Philip A. Ludbrook, MD, FACC; Burton E. Sobel, MD, FACC; and Robert Roberts, MD, FACC, Washington University, St. Louis, Missouri

To define coronary vascular determinants of the high incidence (43%, n=58) of early recurrent infarction (ERI) reported recently in patients with subendocardial as opposed to transmural myocardial infarction (MI) (8%, n=132) we evaluated coronary angiograms in 73 patients in whom initial MI was subendocardial in 33 and transmural in 40. Coronary angiograms were obtained within 48 days. In 17 patients, ERI developed, averaging 10 ± 4 (SD) days after the initial MI, all of whom initially had subendocardial MI. None of the patients with transmural MI exhibited ERI. The ECG site of recurrent MI was concordant with the site of the initial MI in every case. Coronary stenosis exceeding 75% was present in all patients. However, incomplete occlusion was evident in 74% of patients with subendocardial but in only 17% with transmural MI. In patients with subendocardial MI and incomplete coronary occlusion, 58% (14/24) developed ERI compared to only 10% with complete occlusion. Thus, incomplete occlusion is strongly associated with subendocardial MI, a progenitor of ERI. Recurrent infarction was frequently associated with ST elevation resembling that seen in variant angina (71%). In concert the data suggest that coronary spasm superimposed on fixed obstruction is implicated in the genesis of ERI because: 1) ERI is generally presaged by subendocardial MI which in turn is associated with incomplete coronary occlusion; 2) ERI is manifested by ST segment elevation rather than depression; and 3) the ECG locus of the recurrent infarction is concordant with that of the initial infarction with both a reflection of the locus of the angiographically delineated fixed obstruction.

MYOCARDIAL INFARCT EXTENSION: DIAGNOSIS, INCIDENCE, AND CLINICAL SIGNIFICANCE.

Hans D. Strauss, MD, FACC; Ian L. Macdonald, MD; Sally A. Orr; Neil D. Berman, MD, FACC; Andrew J. Buda, MD, FACC, University of Toronto, Toronto, Canada.

The incidence, methods of detection, and consequences of extension (Ext) after myocardial infarction (MI) remain controversial. We studied 80 patients (pts) by serial 8-hourly quantitative CK-MB and daily ECG's for 10 days post MI. There were 67 men and 13 women with a mean age of 64 years (range 44-80 yrs). Mean infarct size assessed enzymatically was 18 ±3 CK gm eq/m2. MI Ext defined by re-elevation of CK-MB, occurred in 28 (35%) at a mean of 5.8 days (range 3-10 days) post MI. MI Ext by ECG (ST segment re-elevation) occurred in 8 (10%). Resting (>15 min) ischemic chest pain (CP)occurred in 25 (32%). The sensitivity (sens), specificity (spec), and positive predictive accuracy (PPA) of ECG, CP, and total CK compared to CK-MB in detecting MI Ext were:

	Total CK	ECG	CP	ECG & CP	ECG and/or CP
sens (%)	14	18	37	33	41
spec (%)	100	87	72	96	64
PPA (%)	80	42	40	40	37

In-hospital mortality after 3 days post MI was 18% in pts with MI Ext by CK-MB compared to 2% in pts without Ext ($p < 0.01$). The risk ratio for mortality was 9.3 in pts with CK-MB Ext, 2.8 with ECG MI Ext, and 8.8 in pts with recurrent CP. No factors predictive of subsequent MI Ext were found. We conclude that MI Ext occurs frequently and is a useful predictor of mortality. ECG and CP are insensitive compared to CK-MB in diagnosing MI Ext.

MYOCARDIAL INFARCT EXTENSION: REASSESSMENT OF INCIDENCE, DETECTION, AND INFLUENCE ON SURVIVAL

John T. Baker, MD, Dean A. Bramlet, MD, Robert M. Lester, MD, David G. Harrison, MD, Charles R. Roe, MD, Frederick R. Cobb, MD, Duke University & VA Med Ctrs, Durham, N.C.

The incidence of myocardial infarct extension(MIE) as detected by precordial ST-segment mapping has been reported to be as high as 86%. Mortality attributed to MIE has varied from 8.3 to 40%. The purpose of this study was to utilize creatine phosphokinase myocardial-specific isoenzyme(CK-MB) activity, a specific serological marker of myocardial necrosis, to determine prospectively the incidence of MIE, the reliability of ST-segment changes to detect MIE, and the relationship of MIE to survival in-hospital after acute myocardial infarction. Routine 12-lead electrocardiograms and plasma CK-MB activity were measured every 12 hours for 10 days in 56 consecutive patients with acute myocardial infarction. MIE was defined as either 1) reappearance of CK-MB activity or 2) re-elevation of CK-MB activity >48 hours after onset of acute myocardial infarction. Additional or new ST-segment elevation ≥ 1 mm beyond 48 hours after onset of acute myocardial infarction was noted. MIE occurred in 14.3%(8/56 patients), a mean of 4.6 days after onset of acute myocardial infarction. CK-MB re-elevation occurred in 75%(6/8) and CK-MB reappearance in 25% (2/8). ST-segment changes occurred in 50%(4/8) of patients with MIE, but also in 45%(17/48) without MIE($p=0.34$). Late hospital mortality was 50%(4/8) with MIE vs 2.1%(1/48) without MIE($p=0.0009$).

We conclude that 1) the incidence of MIE detected by CK-MB is much lower than previously reported with ST-segment mapping, 2) recurrent ST-segment changes on standard electrocardiograms are neither sensitive nor specific indicators of MIE, and 3) MIE as detected by secondary elevation of CK-MB activity >48 hours after acute infarction identifies a subset of patients at high risk for late in-hospital death.

HEART RATE RESPONSES TO HOME ACTIVITIES SOON AFTER MYOCARDIAL INFARCTION

Lois M. Sheldahl, PhD, Nancy A. Wilke, BS, C. Vincent Hughes, MD, Felix E. Tristani, MD, FACC, Cardiopulmonary Rehabilitation Center, Veterans Administration Center and Medical College of Wisconsin, Milwaukee, WI.

Adequate data is not available on the cardiac response to home activities in myocardial infarction (MI) patients (pts) following hospital discharge. Heart rate (HR) response to home activities was determined on 40 pts who underwent 24 hour ambulatory electrocardiographic monitoring (AEM) approximately 3 weeks after MI. Detailed diaries of home activities were kept. The mean peak HR on the AEM was 106±18 bpm compared to a mean peak HR of 113±16 bpm on a low-level graded exercise test (LL-GXT) performed prior to discharge. Fifteen pts (38%) showed a higher peak HR on the AEM compared to the LL-GXT. During home activities, 25 pts (63%) exceeded their upper prescribed HR (resting + 20 bpm) for at least 10 consecutive minutes and 19 (48%) of these pts sustained this elevated HR for at least 30 consecutive minutes. Home activities associated with a HR in excess of prescribed levels included self-care morning activities (n=19), household and shopping activities (n=10), anxiety related events (n=7), and walking (n=4). Angina pectoris was rarely reported. Conclusions: 1) home activities often lead to excessive HR levels in pts 3 weeks post-MI; 2) the increased cardiac stress may be deleterious to some pts; 3) on the other hand, the sustained elevated HR during home activities may be partially responsible for the training effect reported in some post-MI pts not in exercise programs.

THE EFFECT OF EXERCISE PRESCRIPTION ON THE RECURRENCE RATE OF MYOCARDIAL INFARCTION IN MEN

Peter A. Rechnitzer, MD, FACC; Principal and Associate Investigators. The Ontario Exercise-Heart Collaborative Study. University of Western Ontario, London, Ontario, Canada.

This multi-center trial was carried out (1972-1979) to determine whether a program of endurance exercise would reduce the recurrence rate among male patients who had survived an initial myocardial infarction. The study population consisted of 733 men who were randomized into a high intensity exercise (HIE) (379) or a low intensity exercise (LIE) (354) group. Participants in the HIE group were given an individualized exercise prescription designed to produce a significant training effect, while those in the LIE group engaged in mild recreational activities structured to avoid training effect. The overall drop out was 45%. 93% of all drop-outs were followed to the completion of the study. Over the four year intervention period, the total recurrence rate for the HIE group was 9.5% and for the LIE group was 7.3%. Life-Table methods of analysis failed to reveal any significant difference in recurrence rates between the groups. The cumulative relative odds of re-infarction in the HIE group during the time of active participation were 1.24 compared to the LIE group. If re-infarctions after the date of drop-out were included, similar cumulative relative odds of re-infarction in the HIE group were 1.09 compared to the LIE group. Although the re-infarction rate was lower than expected, this study failed to demonstrate that prescribing a program of endurance training was more effective than participation in mild recreational activities in reducing the incidence of fatal and non-fatal re-infarction.

INFLUENCE OF RISK FACTORS IN CARDIOVASCULAR DISEASE
8:30-10:00

A-B CORONARY-PRONE BEHAVIOR PATTERN AND CARDIOVASCULAR RISK FACTOR VARIABLES IN CHILDREN AND ADOLESCENTS: THE BOGALUSA HEART STUDY.

Saundra MacD. Hunter, PhD; Thomas M. Wolf, PhD; Monny C. Sklov, PhD; Larry S. Webber, PhD; Gerald S. Berenson, MD, FACC, L.S.U. Specialized Center of Research--Arteriosclerosis, New Orleans, Louisiana.

The relationship between Total score and Factors derived from a Hunter-Wolf Self-Rating Scale for children and several physiologic risk factor variables related to cardiovascular disease were analyzed as part of a larger study on children, ages 10-17, in a biracial community.

For each sex-race group, four Factor scores and the Total scores were ranked into quintiles. Children in the upper quintile were referred to as Type A children and those in the lower quintile, Type B. For Factor I, "eagergy," e.g., I walk fast, I eat fast, significant mean differences were found for serum total and β- and pre-β-lipoprotein cholesterol and triglycerides. In each instance, children classified as Type A exhibited approximately 10 mg/dl higher readings except for pre-β-lipoprotein cholesterol in which a 2 mg/dl difference was noted. Significant interaction was found between the effects of Factor I behavior, race, and sex on systolic and diastolic blood pressure. Black boys who scored in the Type A direction had higher systolic blood pressures while white Type A girls had higher diastolic blood pressures than their Type B counterparts ($p<0.05$). These observations show it is possible to identify in children behavior characteristics that relate to cardiovascular disease.

RIGHT ATRIAL PACING SOON AFTER MI: DETECTION OF RESIDUAL MYOCARDIAL ISCHEMIA AND PREDICTION OF EARLY PROGNOSIS

Dan Tzivoni, MD; Elihau Gazala, MD; Andre Keren, MD; Chaim Granot, MD; Shmuel Gottlieb, MD; Jose Golhman, MD; Shlomo Stern, MD, FACC, Bikur Cholim Hospital, Jerusalem, Israel

To assess the presence of residual myocardial ischemia and its prognostic significance, right atrial pacing (RAP) was performed in 74 consecutive post MI pts aged 29-85, the day before discharge. No pt was excluded from the study because of clinical status. RAP was performed at bedside and pacing rate was increased by 10 beats every 2 min up to 160/min. Pacing was terminated if >3mm ST depression or severe angina developed. RAP was regarded positive if >1mm ST depression developed. There were no complications. Pacing was performed 10-28 days post MI (mean=14.2). Maximal pacing rate ranged between 100-160/min (mean=148/min). Results (table): 19% of the anterior, 59% of the inferior and 68% of the subendocardial MIs were positive. Follow-up was 1 to 12 months (mean=5.8 months). Among the 39 pts with normal RAP there was 1 sudden death, no reinfarction, and 5 had chest pain. Of the 35 positives there were 3 deaths (2 reinfarctions, and 1 sudden), 5 had reinfarction and 10 had chest pain. Treadmill stress test (TT) was performed in 37 pts 6 months post MI. Of 21 with negative RAP 17 had negative and 4 positive TT; of 16 with positive RAP 12 had positive and 4 negative TT.

Conclusions: RAP can be performed safely soon after MI, is sensitive in detecting residual myocardial ischemia, it can identify pts at risk for reinfarction and probably for death. RAP predicted the presence of exercise induced ischemia 6 months after MI. RAP can be performed in all post MI pts, requires no cooperation and if ischemia develops, it can be stopped immediately.

Infarct pts		Negative		Positive	
Anterior	27	22	(81%)	5	(19%)
Inferior	22	9	(41%)	13	(59%)
Subendo.	25	8	(32%)	17	(68%)
Total	74	39	(53%)	35	(47%)

PLASMAPHERESIS IN THE TREATMENT OF CHILDREN WITH HOMOZYGOTIC TYPE II HYPERLIPIDEMIA

Margo Schleman, MD, FACC; Barbara Schneider, MD; Dept. of Pediatrics, Jefferson Medical College, Philadelphia, PA

Homozygotic children with Fredrickson's Type II hyperlipidemia have severe cholesterolemia and suffer early death from progressive coronary artery disease. We evaluated the use of plasmapheresis in two boys, 8 and 11 years, over a period of 5 and 11 months. Both had disfiguring tendinous and palmar xanthomata. The older boy had aortic stenosis and coronary artery disease proven by cardiac catheterization. Plasma exchange via two venipunctures was performed every two weeks on an IBM cell separator. Plasma volume equal to 6% of body weight was replaced by 5% albumen solution. Acidified citrate dextrose was used for anticoagulation. The total treatment averaged 2½ hours. BP, HR and temperature were monitored. Cholesterol (CHOL), triglyceride (Tg), HDL, total protein, PT, PTT, Ca^{++}, Mg^{++}, electrolytes, CBC, platelets, LDH, SGOT and SGPT were drawn before and after exchange. CHOL was significantly lowered by plasmapheresis. Mean CHOL in the 8 year old fell from 698 mg% to 318 mg% with an average of 5.1 gm CHOL removed per run. Mean CHOL in the 11 year old fell from 890 mg% to 384 mg% with an average of 6.3 gm CHOL removed per run. Marked regression in xanthomata occurred in both boys and no new skin lesions developed during this period. Transient decreases in Tg, HDL, TP, Hgb, SGOT, SGPT occurred immediately following plasmapheresis, but levels returned to normal by the next treatment. No significant changes were seen in platelet count, Ca^{++}, Mg^{++} or electrolytes. PT and PTT became prolonged following the exchange, but were normal at the next treatment. No incidents of hypotension, tachycardia, temperature elevation, or bleeding diathesis occurred during or after therapy. Plasmapheresis lowers CHOL in the child with severe hypercholesterolemia and is well tolerated.

BLOOD PRESSURE RELATED ECHOCARDIOGRAPHIC CHANGES IN ADOLESCENTS AND YOUNG ADULTS. Gregory L. Johnson, M.D., FACC., Carol M. Cottrill, M.D., FACC., Harley E. McKean, Ph.D., J. Morley Kotchen, M.D., University of Kentucky, Lexington, KY.

Of 873 adolescents screened for the presence of hypertension during high school, 126 were evaluated by blood pressure (BP) measurement and echocardiography five years later. The 126 subjects included the upper and lower 5th percentile for blood pressure at the time of initial screening and a random control sample selected from the remainder of the population. Systolic and diastolic BP measurements performed at followup were highly correlated ($p < .002$) with initial values and ranged from 94-188 systolic and from 42-106 diastolic. Echographic exam demonstrated that when results were corrected for differences in body mass, there was no relation between either systolic or diastolic BP and LV chamber dimensions, septal thickness, LV wall diastolic thickness or calculated cardiac mass. Subjects with higher systolic BP did demonstrate significant ($p < .01$) increases in resting heart rate, percent fiber shortening, mean velocity of circumferential fiber shortening, LV preejection period/ejection time ratio and both degree and rate of LV systolic wall thickening. Diastolic BP correlated only with degree of systolic wall thickening. These changes were independent of body mass.

Early in the course of systolic hypertension increased work, rather than hypertrophy, appears to be the primary cardiac manifestation of elevated BP. Therapeutic intervention at this point may prevent the consequences of subsequent cardiac hypertrophy.

RELATIONSHIP BETWEEN PLASMA TESTOSTERONE AND LIPOPROTEIN CHOLESTEROL

Lewis H. Kuller, MD, James Gutai, MD, Ronald LaPorte, PhD, Lorita Falvo-Gerard, MN,MPH and Wanju Dai, MD. University of Pittsburgh, Pittsburgh, Pennsylvania

The distribution of lipoprotein cholesterol, specifically HDLc and triglyceride, is probably primarily determined by hormonal levels. We have studied the relationship between plasma testosterone, known risk factors for HDLc (exercise, obesity, alcohol intake) and the levels of lipoprotein cholesterol and triglyceride in a sample of 247 men participating in the Multiple Risk Factor Intervention Trial (MRFIT).

The free and bound testosterone levels decreased with increasing age. Besides age, the major determinant of free and bound testosterone was obesity. Also, individuals gaining weight had a decrease and those losing weight had an increase in testosterone over a one year period. The free and bound testosterone levels were both directly correlated with the HDLc levels and inversely with triglycerides. (Table below) The relationship between testosterone and HDLc and triglycerides persisted even after adjusting for obesity and other determinants of HDLc. Change in plasma testosterone levels and perhaps other hormones, secondary to lifestyle modifications, such as weight change, physical activity, and alcohol consumption may be major determinants of the HDLc distribution in the population.

	BOUND TESTOSTERONE (NG/DL) QUINTILES				
	78-533	534-641	642-761	762-936	937-1650
HDLc (MG/DL)	41	44	43	43	48
TRIG (MG/DL)	222	195	183	190	152

CIGARETTE SMOKING AND NON-FATAL MYOCARDIAL INFARCTION IN WOMEN

Charles H. Hennekens, MD; Walter C. Willett, MD; Christopher Bain, MB; Bernard Rosner, PhD; Frank E. Speizer, MD, Harvard Medical School and Brigham and Women's Hospitals, Boston, MA.

The relationship between cigarette smoking and risk of hospitalization for acute myocardial infarction (MI) was evaluated among 121,964 married, female, registered nurses who responded to a postal questionnaire. Among 249 women who experienced a first MI, 159 (64%) were cigarette smokers at the time of hospitalization. Of 4980 controls matched 20:1 to cases on the basis of age, 1850 (37%) were cigarette smokers at the corresponding time. Cigarette smokers experienced a three-fold increase in risk of MI relative to women who had never smoked (95% confidence limits from 2.3 to 4.0). This relationship was not materially altered by simultaneous adjustment using multiple logistic regression analysis for additional variables which included history of hypertension, diabetes, elevated cholesterol, and family history of MI (95% confidence limits from 2.3 to 4.3). Among current smokers there was evidence for a dose-response relationship with MI. Women who had stopped smoking experienced a risk of MI no greater than those who had never smoked.

RELATION OF EXERCISE ELECTROCARDIOGRAPHIC ST CHANGES TO PHYSIOLOGICAL MEASUREMENTS IN MEN AT HIGH RISK OF FUTURE CORONARY DEATH

Pentti M. Rautaharju, MD, FACC; Steven Broste, MS; Richard S. Crow, MD; Curt Furberg, MD; Ronald J. Prineas, MD, FACC; for the MRFIT Research Group, Dalhousie University, Halifax, Nova Scotia, Canada.

The prevalence of the ischemic response by visual analysis and the computer measurement of 3/8 ST segment integral (STI) was determined through electrocardiographic analysis of the records of 12,866 men chosen for a graded submaximal exercise test in the Multiple Risk Factor Intervention Trial (MRFIT). These men were 35 to 57 years of age and clinically free of coronary heart disease (CHD) and were identified to be in the upper 15% risk group for future CHD death. Multiple regression analysis revealed that STI during peak exercise had a statistically significant positive association with age, diastolic blood pressure, serum cholesterol and fasting blood glucose and a significant negative association with smoking, alcohol consumption, resting heart rate, serum potassium, fasting time preceding the test and body mass index. However, the association between smoking and ST depression was no longer significant when men who did not reach age-specific target heart rate were excluded from analysis. The overall prevalence of computer measured ischemic response (defined as 3/8 STI $\geq 16\mu Vs$ at peak exercise or immediate recovery with STI $<6\mu Vs$ at rest) was 12.45%. The prevalence of ischemic response in visual analysis, using conventional criteria (horizontal or down-sloping ST segment with J-point depression 0.05mV or more) in immediate or 3 minute recovery records was low (2.44%) in this population at high risk of CHD death.

MYOCARDIAL/PULMONARY VASCULAR DISEASE
8:30-10:00

MURINE COXSACKIEVIRUS B4 CARDIOMYOPATHY; MYOCARDIAL INFARCTION AND VENTRICULAR ANEURYSMS.
Riad Khatib, M.D.; Jacob L. Chason, M.D. and A. Martin Lerner, M.D., Wayne State University School of Medicine, Detroit, Mich.

Intraperitoneal inoculation of 48 hr. old mice with 10^4 TCD_{50} Coxsackievirus B4 (Dowell) induces transmural myocardial necrosis and ventricular aneurysms in some of the survivors. The epidemiology and long-term consequences of this "cytopathic" type infection in which maximum virus titers and pathologic changes in the myocardium are synchronous has not been studied. Coxsackievirus B4 infected suckling mice (821 subjects) and sham-inoculated controls (175 subjects) were followed over a 12 month surveillance. Blood and hearts from 10 subjects each were collected (2,5,9, and 30 days; and 2,3,6,9, and 12 months) and clinical findings, ratios of hearts to total weight (HBW), histopathologic findings and neutralizing antibodies (NA) were determined. 679 infected subjects died within 30 days, and 28 more animals succumbed within the next 11 months. Only 44 of the controls died. HBW ratios in both groups were similar throughout. NA did not appear until one month and persisted thereafter. Gross evidence of myocarditis or ventricular aneuyrsms among examined subjects were (25 of 114 subjects (22.8%); 69 of 92 hearts (75%) showed myocarditis histologically. The left ventricular (64 of 69 hearts (92.7%), interventricular septum (39 of 59 hearts (56.5%) and right ventricle (26 of 69 hearts (37.5%) were affected. Transmural scars (or gross ventricular aneurysms were seen in 22 of the 69 hearts (31.8%); left ventricle (16x); I-V septum (5x); right ventricle (5x). Coronary arteries were patent, but the scars resembled myocardial infarctions.

PREALBUMIN IS A COMPONENT OF SENILE CARDIAC AMYLOID
Gibbons G. Cornwell, III, M.D.; Per Westermark, M.D.; Wendy Murdoch, B.S., Dartmouth Medical School, Hanover, NH

We have previously shown that two distinct forms of amyloid may exist in heart tissues of elderly patients. One type, known as isolated atrial amyloid (IAA) is limited to the atrium and has not yet been characterized. The other type, which contains a protein heretofore designated ASc_1, may be present in atrium or ventricle, as well as certain extra-cardiac tissues such as lung and kidney. An antiserum specific for ASc_1 has been used previously to show that this protein is not present in amyloid of the AA type, of the A_λ types or in amyloid associated with medullary carcinoma of the thyroid (MCT) or adult onset diabetes. The present studies show that an antiserum specific for human prealbumin (aHPA) reacts in immunofluorescence with senile cardiac amyloid of the ventricle in a pattern identical to that of anti-ASc_1. This antiserum fails to react with cardiac amyloid of the IAA type, primary amyloid ($A_\lambda I$, $A_\lambda IV$, $A_\lambda VI$), secondary amyloid (AA), amyloid associated with MCT (AE_t), pancreatic amyloid associated with adult onset diabetes, cerebral amyloid present in Alzheimer's disease, or lichen amyloid. The reaction of aHPA is completely blocked by purified prealbumin but is not influenced by absorption with purified human albumin or proteins from any amyloid types tested. The aHPA reaction is also totally blocked by purified protein ASc_1, and the reaction of anti-ASc_1 is similarly blocked by purified human prealbumin. These studies strongly suggest that senile cardiac amyloid of the ASc_1 type contains prealbumin or a protein immunologically identical to this molecule. This finding is similar to that reported for the heredofamilial type of amyloid which has also been reported to contain human prealbumin.

CORRELATIONS OF FIBROSIS IN LEFT VENTRICULAR ENDOMYOCARDIAL BIOPSIES FROM PATIENTS WITH AORTIC VALVE DISEASE.
Paul Oldershaw, MRCP, John Coltart, FRCP, Stephen Jenkins FRCP, Michael Webb-Peploe FRCP.

St. Thomas' Hospital, London. SE1 England.

Exercise tolerance remains poor after aortic valve replacement in patients (pts) who have impaired left ventricular (LV) function preoperatively; the reasons for this are not clear. We have assessed the role of structural changes in the myocardium in limiting postoperative exercise tolerance by measuring percentage fibrosis (PF) in preoperative LV biopsies and comparing this with 1) other data obtained at catheter and 2) with the patients clinical status at follow up. PF was measured using a standard point-counting technique. Biopsy specimens were obtained from 55 pts with aortic stenosis (mean age 59 yrs) and 42 pts with aortic regurgitation (mean age 48 yrs). Fibrosis was present in 33 (60%) of the pts with aortic stenosis and there was a significant correlation between PF and LV ejection fraction ($r = 0.72$, $p < 0.01$). Mean peak systolic gradient was significantly higher in pts with fibrosis (83±4mm Hg) than in pts without fibrosis (67±6mm Hg) ($p \leq 0.01$). By contrast, fibrosis was found in only 17 (40%) of the 42 pts with aortic regurgitation and was never severe. There was no correlation between PF and ejection fraction or degree of regurgitation. In both groups of pts (stenosis and regurgitation) there was strong correlation between PF and patients' follow up symptomatology, need for antifailure treatment and mortality. We conclude that PF may be a prognostic indicator in pts with aortic valve disease.

THE CARDIAC DISEASE OF MYOTONIC MUSCULAR DYSTROPHY.
Nigel K. Roberts, MD, FACC, William R. Cabeen, MD, FACC, and Joseph K. Perloff, MD, FACC, UCLA School of Medicine, Los Angeles, CA.

In myotonic muscular dystrophy (MMD)—a systemic disease characterized by dystrophy, myotonia and features of premature aging—the relative importance of electrophysiologic and myocardial involvement has not previously been studied in the same patient population. Accordingly, we investigated 15 subjects, 7 males and 8 females with active MMD (electromyography, biopsy, elevated CPK). Average age was 36 years. Males were less than 40 years. Females were premenopausal. No patient was diabetic. Average disease duration was 15 years. Cardiac symptoms were confined to palpitations in 4/15. Cardiac electrical activity was studied by electrocardiography, vectorcardiography, ambulatory monitors and intracardiac multiple electrode catheters. Ventricular function, wall motion and chamber size were studied by M mode and 2 D echocardiography, and technetium (^{99m}Tc) radionuclide angiocardiography. Results: left anterior fascicular block (LAFB) 8/15; supraventricular tachycardia 3/15 (2 triggered); ↑ sinus node recovery time 2/15; ↑ atrial refractory period 5/15; ↑ AV node conduction 1/15 (with atrial pacing); ↑ HV conduction 8/15, borderline 2/15 (55 msec), normal in 2/15 with LAFB; entirely normal studies 2/15. Pharmacologic denervation yielded no increase in abnormalities. ^{99m}Tc angiocardiography: ejection fraction (EF) 50-73% (av 58); wall motion normal (no dystrophy or myotonia). Echocardiography: EF 50-80% (av 67); % fractional shortening 30-48 (av 34), chamber size and wall motion normal. Conclusions: Cardiac disease in MMD selectively disturbs impulse formation and conduction, especially infranodal, with no detectable abnormalities of contraction. The electrophysiologic abnormalities resemble those of aging, and may be yet another feature of the progeria of MMD.

THE NATURAL HISTORY OF IDIOPATHIC PULMONARY HYPERTENSION
Valentin Fuster, MD, FACC; Emilio R. Giuliani, MD, FACC; Robert O. Brandenburg, MD, FACC; William H. Weidman, MD, FACC; William D. Edwards, MD, FACC, Mayo Clinic, Rochester, Minnesota

The study comprises 100 consecutive patients (pts) with idiopathic pulmonary hypertension (IPH) by clinical and hemodynamic criteria and followed up for a median of 10 years (yrs) (range 4-24). The initial clinical manifestation was dyspnea (78 pts), exertional dizziness (15 pts), fatigue (4 pts), exertional chest pain (3 pts). At diagnostic study, the average pulmonary artery pressure was 96/43 mm Hg (range 51-208/25-107). Seventy-four pts were female and 26 males. Median age was 30 yrs (range 2-70) at the time of first clinical manifestation and 33 yrs (range 3-70) at the time of diagnostic study. The incidence of thrombophlebitis (6 pts) and of the use of oral contraceptives (13 pts) did not appear to differ from that in the general population.

From the time of hemodynamic diagnosis, 91 pts were dead at a median interval of 2 yrs and 9 pts had survived for at least 4 yrs. From analysis of all probable predictive clinical and hemodynamic factors, only the use of anticoagulants (A/C) initiated at the time of diagnosis in 36 pts appeared to show a beneficial trend; of the 9 survivor pts, 5 were taking A/C; in the nonsurviving pts who had been taking A/C (31 pts) average survivorship was 1 yr longer.

In summary, this large and long-term followup study on IPH revealed that this disease predominates in young women, it is diagnosed when the disease is already too advanced, and its course to death is very short. Anticoagulants may be of benefit, but usually are initiated too late in the course of the disease.

COMPARATIVE HEMODYNAMIC AND CLINICAL RESPONSES TO ISUPREL, DIAZOXIDE AND HYDRALAZINE IN SEVERE PRECAPILLARY PULMONARY HYPERTENSION
Charles R. McKay, MD; Kanu Chatterjee, MB, FRCP, FACC; Gilbert L. Raff, MD; Bruce H. Brundage, MD, FACC; William W. Parmley, MD, FACC, University of California, San Francisco, Ca.

Acute resting hemodynamic responses to Isuprel (I) (0.5 to 2.0 µg/min.I.V.), hydralazine (H) (25 to 100 mg. p.o.) and diazoxide (D) (50 to 350 mg. I.V.) were determined in 7 patients (PTS) with severe precapillary pulmonary hypertension (PPH). No drug had significant beneficial effects on mean pulmonary artery pressure (PA) or total pulmonary resistance (TPR) for the entire group of PTS. All 3 drugs significantly increased cardiac output (CO), primarily due to increased heart rate (HR). I and D significantly decreased total systemic resistance (TSR) without decreasing TPR. Control = C; Therapy = T

	HR (beats/min.)		CO (L/min./m^2)		PA (mm.Hg)		TPR (dynes.sec.cm-5)		TSR	
	C	T	C	T	C	T	C	T	C	T
I	85†	104	4.1	5.8†	55	66	1055	985	1855	1377*
H	93	99	4.6	5.3**	62	63	1207	1107	1700	1404
D	94	100	3.8	5.1††	53	54	1012	950	1899	1432**

p <.05*, p <.025**, p <.005†, p <.001††

Four of the 7 PTS had decreased PA pressure or TPR associated with increased stroke volume, and were continued on oral H (2 PTS) or D (2 PTS). One PT continues symptom free at 10 months on D. Three other PTS had drug related complications preventing long term therapy. Limited improvement and adverse effects of acute and chronic therapy caution against the empirical use of these drugs in PPH without hemodynamic documentation of their efficacy in individual PTS.

THALLIUM-201 MYOCARDIAL PERFUSION IMAGING IN WOMEN: CORRELATION WITH CORONARY ARTERIOGRAPHY
William Ceretto MD FACC, Victor Vieweg MD FACC, Robert Slutsky MD. Naval Regional Medical Center and University of California, San Diego

Thallium-201 myocardial perfusion imaging (MPI) has been shown to be a sensitive and specific technic in the diagnosis of coronary artery disease (CAD) in men. While the difference between treadmill sensitivity for CAD in men and women is well known, as yet similar data are not available for MPI. Thus we utilized stress and reperfusion MPI in 30 female patients with chest pain prior to coronary arteriography.

	+THALLIUM	-THALLIUM
+ CAD (n=13)	4 (31%)	9 (69%)
- CAD (n=17)	3 (18%)	14 (82%)

In general, pts with CAD and negative scintigrams had a lower peak exercise heart rate (68.7+ 10.5% predicted vs. 83.3 + 13% predicted $p < .05$) than pts with CAD who had perfusion abnormalities. Of the 9 pts with false negative studies, 7 were ingesting propranolol, 6 long acting nitrates, and 6 did not reach 80% of their predicted heart rate. One had single vessel disease. Three subjects had false positive studies, two had mitral valve prolapse and one had diabetes mellitus and a positive treadmill ECG response. Thus in this study, the sensitivity of thallium MPI was poor (31%) and the predictive accuracy of a positive test low (61%), although any number of factors may have influenced the results. We thus conclude that thallium-201 MPI in women with chest pain is limited in utility, particularly in subjects with mitral prolapse or those ingesting propranolol.

EXERCISE TESTING OF WOMEN WITH CHEST PAIN WITH AND WITHOUT THALLIUM TOMOGRAPHY
Ivan Pacold, MD; Paul T. Maier, MD; John F. Moran, MD, FACC; David J. Hale, MD, FACC; Robert Henkin, MD; Rolf M. Gunnar, MD, FACC, Loyola University Medical Center, Maywood, Il and Hines VA Hospital, Hines, Il

Women with angina-like chest pain frequently develop falsely abnormal ST segment depression on multistage exercise testing (MET). Ninety-six female patients (pts) with chest pain were studied with MET and coronary angiography. ST segment depression of 1 mm or more on exercise and 50% or more reduction in diameter of any coronary artery were considered abnormal.

MET was abnormal in 40 of 96 pts. Thirty of these 40 pts had normal coronaries. MET was normal in 56 of 96 pts. Forty-nine of these 56 pts had normal coronaries. The sensitivity of MET was 58% and specificity 62%. Analysis by duration of exercise (3 min or longer) or by maximal systolic BP (130 mmHg or higher) did not improve these findings.

Additional 32 pts were studied with MET, coronary angiography and with stress/rest thallium planar and seven pinhole tomographic images. Reversible and irreversible defects on thallium scans were considered abnormal.

The thallium scan was abnormal in 17 of 32 pts. Five of these 17 pts had normal coronaries. The thallium scan was normal in 15 of 32 pts. Ten of these 15 pts had normal coronaries. The sensitivity of the thallium scan was 71% and specificity 67%.

Although the thallium scan may be more sensitive than MET in the detection of coronary disease in women, the usefulness of MET and the thallium scan in the evaluation of women with chest pain is limited by the low specificity of either test in this patient population.

ABNORMAL BLOOD PRESSURE RESPONSE DURING AN EXERCISE TEST

Ricardo Bessoudo, MD; Robert N. Anderson, MD, FACC; Dalhousie University, Halifax, Nova Scotia, Canada.

Patients (pts) with coronary artery disease (CAD) in contrast to normals (N), have less increase or a fall in systolic (SYS) blood pressure (BP) during exercise (EX). In order to assess the BP changes during early recovery (R) from EX, we studied 130 pts, 104 males and 26 females (mean age 52 years) who underwent a submaximal bicycle EX test (T) prior to coronary arteriography. BP was recorded during all stages of EX and R. Critical CAD ($\geq$70% luminal narrowing) was present in 88 pts: 26 with 1 vessel disease (1VD); 30 with 2 vessel disease (2VD); and 32 with left main or 3 vessel disease (LM-3VD). 42 were N.
Of the 130 pts, 90 had a fall in BP during the first minute of R and 40 had a rise (RI) in BP during this period. Of the pts with BP RI, 6 had 1VD, 12 had 2VD, 19 had LM-3VD and 3 were N. The sensitivity (SEN), specificity (SP) and the predictive value (PV) of SYS BP RI in R as compared to that for ECG changes (Δ) (0.1 mV. ST depression at 80 m/sec) were as follows:

	SEN%	SP%	PV%
ECG Δ	51	90	92
SYS BP RI	42	93	93

For LM-3VD, results were:

ECG Δ	72	73	47
SYS BP RI	59	79	48

Thus, SYS BP RI during the R period of an EX T is almost as useful as ECG Δ in the diagnosis of CAD.

SENSITIVITY OF EXERCISE INDUCED CHANGES IN APEX OF T TO END OF T AND QT INTERVALS FOR DETECTING CORONARY DISEASE

Jacqueline O'Donnell, MD; Suzanne B. Knoebel, MD, FACC; D. Eugene Lovelace, BS; Paul L. McHenry, MD, FACC, Krannert Institute of Cardiology, Indiana University School of Medicine, Indianapolis, Indiana

Exercise-induced myocardial ischemia may result in nonhomogeneous repolarization which is reflected as changes in the QT and apex of T to end of T (aT-eT) intervals. We have studied the sensitivity and specificity of the aT-eT interval and the aT-eT/QT ratio for detecting coronary artery disease (CAD). The QT and aT-eT intervals were quantitated using computer-averaged QRS-T complexes and a computer program developed in our laboratory. Measurements were made on resting and exercise ECG recordings from a group of normal male subjects and a group of male pts. with angiographically documented CAD. The two groups were matched for age and heart rate. The QT interval measurements did not differ significantly between the two groups at rest. During exercise there were significant differences between the two groups in the aT-eT interval and the aT-eT/QT ratio.

	No. Pts.	aT-eT(msec)	QT(msec)	aT-eT/QT
NORMALS*	51	73.7	303.7	23.9
CAD PTS.*	29	60.6	305.4	18.9
		(p<0.01)		(p<0.001)

* Mean age 50; Mean Exercise H.R. 123/min.

The sensitivity and specificity of an aT-eT/QT ratio of <22% for underlying CAD was 82% and 70% respectively. The sensitivity of an aT-eT ratio of <22% and/or $\geq$1.0 mm. horizontal ST depression was 95%. We conclude that measurement of exercise QT interval changes is feasible using computer techniques and they show promise for inhancing the diagnostic capabilities of the exercise ECG.

PRECORDIAL ELECTROCARDIOGRAPHIC MAPPING IN THE IDENTIFICATION OF PATIENTS WITH LEFT MAIN STEM DISEASE.

John E. Deanfield, MB; Kim M. Fox, MB; Anne Jonathan; Andrew P. Selwyn, MB, Hammersmith Hospital, London, England.

The introduction of 16 lead precordial ECG mapping in exercise testing provides additional information not available using conventional lead systems. The value of this technique in identifying patients with left main stem (LMS) disease has been investigated in 50 patients. Over the same period, 90 patients with 3 vessel and 42 patients with single vessel disease were similarly investigated. The work load achieved was significantly lower in patients with LMS disease than the other two groups ($P<0.01$). Likewise the exercise-induced area and severity of ST-changes was greatest in patients with LMS narrowing ($P<0.01$). Discriminative function analysis showed that patients with LMS disease could be identified from the area and site of exercise-induced ST changes on the precordial map. Forty-four (88%) patients with LMS narrowing developed ST-changes on the uppermost row of the surface map; a finding, with 3 exceptions, that otherwise only occurred in patients with proximal left anterior descending coronary artery narrowing. This study therefore demonstrates the value of precordial exercise mapping in identifying patients with LMS disease.

THE SIGNIFICANCE OF BIPHASIC R WAVE AMPLITUDE CHANGES DURING INCREMENTAL ATRIAL PACING: A SENSITIVE AND SPECIFIC MARKER FOR ACUTE MYOCARDIAL ISCHEMIA

Daniel David, MD, James G. Kitchen, MD, FACC, Chin C. Chen, MD, Joel Morganroth, MD, FACC, Eric L. Michelson, MD, FACC, A.N. Moghadam, MD, FACC, Masahito Naito, MD, Leonard S. Dreifus, MD, FACC, Thomas Jefferson University and Lankenau Hospital, Philadelphia, PA

An increase in R wave amplitude (RWA) during exercise testing has been suggested as a marker for myocardial ischemia. This has been attributed to the "Brody effect" whereby ischemia results in an increase in LV volume. This study was designed to determine RWA response to myocardial ischemia induced by atrial pacing (AP). Twenty one patients (PTs) underwent AP during which the sum of RWA (ΣR) changes in leads X,Y,Z and V5 were correlated with the extent of angiographically determined CAD, resting LV end diastolic pressure (LVEDP) and ejection fraction (EF) as well as dynamic LV dimensional and functional changes during AP measured by 2D echocardiography in the short axis and apical view. Eleven of 13 (86.6%) PTs with negative AP showed a significant decrease in ΣR at 100/min ($p< 0.01$) followed by a further significant decrease in ΣR at 150/min ($p< 0.01$). In contrast, 7/8 (87.5%) PTs with positive AP demonstrated an initial significant decrease in ΣR at 100/min ($p< 0.01$) followed by a significant increase in ΣR at 150/min ($p < 0.01$). These patterns of ΣR changes during AP were not dependent on the degree of fixed CAD, the LVEDP or the EF either at rest or during AP. Thus, the distinctive pattern of an initial decrease followed by an increase in ΣR during incremental AP is a sensitive and specific marker for the occurrence of myocardial ischemia. This ischemic pattern is independent of both the degree of fixed coronary obstruction and left ventricular dimensional changes.

CARDIAC SURGERY—2
10:30-12:00

THE IMMEDIATE POST-EXERCISE VENTRICULOGRAM: A SCINTIGRAPHIC TOOL FOR THE PRE-OPERATIVE ASSESSMENT OF REVERSIBLE MYOCARDIAL ASYNERGY

Alan Rozanski, MD; Daniel Berman, MD, FACC; Ronald Levy, MD; Richard Gray, MD, FACC; Marjorie Raymond, RN; Jamshid Maddahi, MD; James Forrester, MD, FACC; Alan Waxman, MD; H.J.C. Swan, MD, FACC; and Jack Matloff, MD, FACC.
Cedars-Sinai Medical Center, Los Angeles, California.

Since with upright exercise, normalization of resting LV asynergy (asyn) is frequently observed during the immediate post-exercise (IMPEX) period, the IMPEX response might be a useful pre-operative (op) indicator of latent mechanical myocardial function. Thus, we compared LV wall motion (WM) response IMPEX and following coronary artery bypass surgery (CABG) in 31 patients with coronary artery disease who underwent both pre-op 45° LAO multiple gated equilibrium scintigraphy (MGES) with sitting bicycle exercise and post-op resting MGES, using Tc-99m-RBCs. For each image, the LV was divided into 5 segments (segs) and WM assessed by a 5-point system (3=normal, -1=dyskinesis). Because of known effects of CABG on septal motion, this region was excluded from analysis. Pre-op asyn segs were considered improved IMPEX or post-op if WM=3 or increased $\geq$2 from control. Post-op and IMPEX images were separately compared to pre-op images. Of 35 pre-op asyn segs, the IMPEX response correctly predicted post-op WM in 27, including 16/23 segs which improved and 11/12 with no improvement ($p \leq 0.01$). Importantly, the IMPEX response was highly specific for reversible asyn: of 17 asyn segs improving IMPEX, 16 improved after CABG.

In conclusion: 1) post-operative improvement of resting asynergy occurs frequently, 2) the IMPEX response appears to differentiate segments with reversible and non-reversible asynergy, and 3) this response may thus be of clinical use in the pre-operative assessment of patients with resting left ventricular wall motion abnormalities.

RIGHT AND LEFT VENTRICULAR PERFORMANCE BEFORE AND AFTER CORRECTION OF MITRAL STENOSIS

Vincent C. DiCola, M.D., Charles A. Boucher, M.D., FACC, William H. Shea, Jr., B.S., Robert D. Okada, M.D., FACC, Frederick H. Levine, M.D., FACC, Demetrios Lappas, M.D. H. William Strauss, M.D., FACC, Gerald M. Pohost, M.D., FACC. Massachusetts General Hospital, Boston, MA.

The changes in RV and LV ejection fraction (EF) were assessed in relation to hemodynamics in 14 patients with isolated mitral stenosis (MS). RVEF was determined by both gated first pass (FP) and gated equilibrium (EQ) radionuclide methods and LVEF by EQ alone. Mean PA pressure (PAP), pulmonary vascular resistance (PVR), cardiac index (CI) and mean LA pressure (LAP) were recorded pre- and 1-2 days postoperativley. Mean $\pm$1 SD values follow:

	Preop	Postop	p
RVEF-FP	0.49$\pm$.13	0.60$\pm$.11	< .01
RVEF-EQ	0.35$\pm$.08	0.45$\pm$.09	< .001
LVEF-EQ	0.59$\pm$.10	0.58$\pm$.08	NS
PAP (mm Hg)	34$\pm$15	25$\pm$6	< .01
PVR (units)	5.2$\pm$2.5	3.2$\pm$1.8	< .001
CI (L/min/M^2)	2.4$\pm$0.4	2.7$\pm$0.4	< .05
LAP (mm Hg)	22$\pm$11	16$\pm$2	< .05

Preop FP RVEF correlated significantly with mitral valve area ($p<.05$). The increase in RVEF was larger in patients with lower preop RVEF ($r=-.62$, $p<.05$).
In conclusion, blood pool scanning permits further insight into the impact of mitral valve surgery on RV and LV function in MS. As assessed by 2 methods, RVEF is depressed preoperatively in relation to the severity of the MS and improves substantially postop. This improvement occurs in association with improved hemodynamics. LVEF is normal preop and does not change postoperatively.

OPERABILITY OF ADULTS WITH LEFT TO RIGHT SHUNTS, CYANOSIS, AND PULMONARY VASCULAR OBSTRUCTION

Verdi DiSesa, MD, William Grossman, MD, FACC, and Lawrence H. Cohn, MD, FACC, Harvard Medical School, Brigham and Womens Hospital, Boston, Massachusetts 02115

Patients with left-to-right shunts who develop desaturation, severe pulmonary artery hypertension (PAH), and marked functional disability have been considered inoperable or at very high risk for ablation of the shunt.

Four patients (22-45, 32 years) with an atrial septal defect, ventricular septal defect, patent ductus arteriosus and Pott's shunt with Tetralogy, respectively presented with functional class IV symptoms, mild cyanosis (mean arterial saturation = 90% (88-92)), PAH ($\overline{PA}$ of 50-83, 66), R_p/R_S of 0.29-0.43, 0.36, and while right-to-left shunt was present in all patients, the net Q_p/Q_S was 1.3-2.8, 1.9. PA pressure did not fall in 3/4 breathing 100% O_2 and two had class IV-V pulmonary hypertensive lung changes on biopsy.

All survived operation, became acyanotic and are functional class I-II, 15-72 months postoperatively. All were recatheterized 4-18 months postoperatively: defects were closed, the $\overline{PA}$ pressures were 26-45, 35 and R_p/R_S were 0.16-0.60, 0.39.

Patients with left-to-right shunts who develop cyanosis and severe pulmonary vascular obstruction may still be candidates for surgical correction if Q_p/Q_S is net left-to-right and if R_p/R_S is less than 0.50.

MYOMECTOMY AND MITRAL VALVE REPLACEMENT FOR IDIOPATHIC HYPERTROPHIC SUBAORTIC STENOSIS: FIVE YEAR FOLLOW-UP.

Robert D. Leachman, MD, FACC, Zvonimir Krajcer, MD, FACC, Denton A. Cooley, MD, FACC, Texas Heart Institute, Houston, Texas.

To assess the long term results of myomectomy (MYOM), mitral valve replacement (MVR) or combination of both in 36 patients (pts) with idiopathic hypertrophic subaortic stenosis (IHSS) pre- and postoperative cardiac catheterization, functional classification (FC) and mortality were analyzed. The follow-up was from 5 to 67 months (mean 48). Hemodynamic measurements included LV outflow tract gradient (LVOTG) at rest and with provocation and LV end-diastolic pressure (LVEDP) in mmHg. There was no operative mortality. There were three late post-operative deaths. Two had MVR and one had MYOM. They all had preoperatively severe congestive heart failure (CHF), FC IV and LVEDP > 20 mmHg.

	Preop (36)	MVR (13)	Postop MYOM (12)	MVR$\pm$MYOM (11)
FC	35 III & IV	10 I & II	12 I & II	11 I & II
LVOTG REST	72 $\pm$42	3 $\pm$ 6***	35 $\pm$15**	0****
LVOTG PROV	143 $\pm$56	4 $\pm$ 9****	78 $\pm$21***	0****
LVEDP	22 $\pm$11	14 $\pm$ 5*	19 $\pm$14	16 $\pm$7

*=p <0.05; **=p <0.02; ***=p < 0.01; ****=p <0.001

Our findings indicate that surgery for IHSS carries a low operative risk, offers marked symptomatic improvement and produces significant reduction in LVOTG and LVEDP. MVR or MVR plus MYOM was more effective than MYOM alone in reducing resting and provocative LVOTG and LVEDP. Pts with severe CHF, FC IV and significantly elevated LVEDP have less favorable long term post-operative prognosis.

OPEN MITRAL COMMISSUROTOMY: LATE FOLLOW-UP OF 108 PATIENTS

Daniel J. Ullyot, M.D, FACC; Benson B. Roe, M.D, FACC; Noel Fishman, M.D; John Mack, M.D; Kevin Turley, M.D, FACC; Paul A. Ebert, M.D, FACC, University of California, San Francisco, California.

During the period January 1965 through July 1979 145 patients were operated on for isolated mitral stenosis. 128 had an open operative approach and only 13% (17/128) required mitral valve replacement. 111 patients underwent open mitral commissurotomy with a hospital survival of 97% (108/111).

These 108 patients were followed a mean of 6.5 years (range 1-15). There were 101 women and 7 men, mean age 46 years (range 23-67), NYHA classification I (1%) II (30%) III (64%) IV (5%), mean valve area .94 square centimeters (range 0.4-1.8).

There were 7 late deaths, one due to cardiac and 6 of either non cardiac (3) or unknown (3) cause. Twenty required subsequent mitral valve surgery either mitral valve replacement (18) or a second open commissurotomy (2). Seven had systemic thromboembolic events. Seventy eight percent were in NYHA class I or II at recent follow-up. Life table analysis showed:

	Cumulative % (S.E.)		
	5 yr.	10 yr.	15 yr.
Survival	97 (1.9)	92 (2.6)	89 (3.5)
Reoperation-free	92 (2.9)	83 (4.2)	75 (5.2)
Embolus-free	99 (1.0)	94 (2.5)	89 (3.6)

Results demonstrate that when open mitral commissurotomy is possible, excellent symptomatic improvement, prolongued survival, and a low incidence of reoperation and/or embolization can be expected.

REPAIR OF RHEUMATIC AORTIC REGURGITATION IN ADOLESCENCE

George E. Reed, M.D., FACC, Richard A. Moggio, M.D., Richard W. Pooley, M.D., Eugenie F. Doyle, M.D., FACC, Brian Kiely, M.D., and Monika Rutkowski, M.D., Dept. of Surgery, N.Y. Medical College, Valhalla, N.Y.

The management of severe rheumatic aortic regurgitation in young people continues to be difficult. The reported early failure as a result of calcification of porcine prostheses in young patients suggests that aortic prostheses and the need for continuous anticoagulation remain serious problems in this group.

A concept of repair is presented in which three dimensional anatomy is restored by creating fuller cusps. This permits apposition both horizontally and vertically over a wide area. The technique involves insertion of a "T" shaped gusset of antologous tissue which has been formed by measurement and which allows for shrinkage.

Five children have been operated upon and have been followed for from 18 months to 13 years. Three of the five patients had mitral repair in addition to aortic valvuloplasty. One patient was reoperated four years later; both mitral and aortic valve required replacement. Sustained good results in the others have been documented clinically and by repeat cardiac catheterization in three.

At minimum this operation permits growth of the aortic root so that a suitably large prosthesis can ultimately be inserted if necessary.

VALVULAR HEART DISEASE
10:30-12:00

HAS ECHOCARDIOGRAPHY ANY PLACE IN DETERMINING THE TIMING OF OPERATION IN AORTIC REGURGITATION?

Martin St. John Sutton, MD, Nathaniel Reichek, MD, John Hirshfeld MD, John Kastor MD, FACC, University of Pennsylvania, Philadelphia, PA.

In chronic aortic regurgitation(AR) valve replacement is advised in patients(pts), 1) with symptoms, and, 2) with LV end-systolic echo diameter $\geq$5.5 cm. To reassess the value of echocardiography in the management of pts with AR we compared the preop LV echoes from 20 symptomatic (NYHA class 3 or 4) pts (group 1) who underwent surgery, with 23 asymptomatic pts (group 2) treated medically, (for a mean of 2 years), to determine whether these 2 groups could be distinguished. All pts were catheterized and had severe AR and normal coronary arteries. LV echograms were digitized and analyzed by computer so that measurements could be made of LV diameter(D) and wall thickness(W) at end-systolic(s) and end-diastole(d), peak rates of LV shortening(VCF), LV filling, dD/DT, and wall thickening, +dW/dt, and wall thinning, -dW/dt.

	Ds	Dd	Wd	VCF	dD/dt	+dW/dt	-dW/dt
Group 1	4.7	7.0	1.1	2.2	16.5	3.7	8.6
	$\pm$0.6	$\pm$0.6	$\pm$0.1	$\pm$0.4	$\pm$4.5	$\pm$0.8	$\pm$2.0
Group 2	5.1	7.0	1.2	1.9	14.5	3.3	5.8
	$\pm$0.9	$\pm$0.6	$\pm$0.3	$\pm$0.5	$\pm$4.0	$\pm$1.0	$\pm$2.2

Eight pts had LVDs >5.5 cm 5 in group 1 and 3 in group 2, but there were no significant differences between the two groups in, 1) LV size, 2) LV hypertrophy(Wd), 3) peak VCF 4) peak LV filling rate, 5) peak rate of wall thickening or thinning. Since echo could not distinguish surgically treated (group 1) pts from medically treated pts (group 2) in terms of LV function, we conclude that no single or combination of echo measurements should be used to recommend operation in pts with chronic AR.

NONINFLAMMATORY AORTIC ROOT DISEASE: AN IMPORTANT CAUSE OF AORTIC REGURGITATION. ECHOCARDIOGRAPHIC AND HISTOPATHOLOGIC CORRELATION.

Timothy Guiney, MD, Graham Leech, MA, Michael J. Davies, FRCPath., Alan Wilson, FRCR, John Parker, FRCS, and Aubrey Leatham, FRCP. St. George's Hospital and Medical School, London, England.

Seventy-one consecutive patients undergoing aortic valve replacement for isolated aortic regurgitation (AR) in a 4 year period were assessed with preoperative M-mode measurement of aortic root diameter (ARD) and the results compared with gross and histologic examination both of the cusps removed and of aortic wall biopsies taken at surgery. Of those patients with ARD $<$37mm 40/42 (95%) had normal aortic wall histology but disease of the aortic cusps (rheumatic, endocarditis, etc.) causing the AR. Of those with ARD $\geq$ 37mm 24/29 (83%) had normal cusps but aortic wall disease accounting for the AR. Only 6 of these patients had inflammatory root disease (lues, giant cell arteritis, Reiter's, etc.). The remainder demonstrated patchy disruption of smooth muscle and particularly of elastic laminae without inflammatory cell infiltration. Twenty of the entire series of 71 patients (28%) proved to have noninflammatory aortic root disease, leading to aortic root dilatation and aortic regurgitation on that basis. Noninflammatory aortic root disease, the most common cause of severe AR in this group, was noted more frequently in those of British ancestry than in minority or immigrant group patients in whom rheumatic etiology was more prevalent. The progression of symptoms was more rapid than in the rheumatic group, but slower than in those with endocarditis.

This group of patients, with a common but poorly recognized cause of severe AR, can be readily identified noninvasively and may require closer pre-symptomatic follow up than those with more slowly progressing types of AR.

EFFECT OF PROLONGED PRAZOSIN TREATMENT ON THE HEMODYNAMICS AND CARDIAC ELECTROLYTES AND Na^+-K^+-ATPase IN DOGS WITH CHRONIC AORTIC STENOSIS

Cathey L. O'Neil, BSc; Bakunth Bharadwaj, MD, FACC, Kailash Prasad, MD, Ph.D, FACC, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

It has been shown that there is a decrease in the cardiac function and intracellular calcium and an increase in the cardiac ATPase in dogs with chronic aortic stenosis. Prazosin, has been used in the treatment of congestive heart failure. It is, however, not known whether Prazosin gives only haemodynamic benefit with accompanying subjective improvement or if there is an actual improvement in the condition of the myocardium in terms of electromechanical and biochemical changes. The present investigation therefore, deals with the effect of prolonged treatment with Prazosin on the cardiac function, electrolytes, and ATPase in dogs with chronic aortic stenosis. Aortic banding was performed in 18 dogs after chest X-ray, ECG and haemodynamic parameters were assessed. Two groups each of 6 dogs were sacrificed at 3 and 6 months after aortic banding. Another group of 6 dogs was treated with Prazosin for 3 months after 3 months of aortic banding and then sacrificed. There was a significant decrease in the cardiac function and contractility associated with an increase in the cardiac ATPase and a decrease in the intracellular calcium at 3 and 6 months of aortic banding and that was more so at 6 than at 3 months. Prazosin produced a marked improvement in the myocardial function, a decrease in the ATPase and an increase in the intracellular calcium. These results indicate that Prazosin not only tended to reverse the cardiac function and contractility to control levels but also tended to reverse the ATPase and intracellular Ca^{++} towards control levels.

AORTIC INPUT IMPEDANCE IN MITRAL REGURGITATION

Wilmer W. Nichols, PhD, FACC; Carl J. Pepine, MD, FACC; Jawahar Mehta, MD, FACC; Leonard G. Christie, JR., MD, FACC; C. Richard Conti, MD, FACC, University of Florida, Gainesville, Florida

To define the effects of mitral regurgitation (MR) on the systemic vascular system pulsatile pressure-flow analysis was performed in 19 patients. The aortic input impedance spectrum was determined from recordings of high fidelity pressure and flow waves (multisensor catheter) obtained from the ascending aorta. Eight patients had clinical and hemodynamic evidence of 3+ to 4+ MR. The other eleven patients had no evidence of heart failure or valvular heart disease and were used as a control group. In the MR patients, both input resistance (impedance at zero Hz) and characteristic impedance (mean of impedance moduli > 2Hz) were significantly elevated (2202 $\pm$ 206 vs. 1080 $\pm$ 49 dyne-sec-cm^{-5} and 123 $\pm$ 7.5 vs. 73 $\pm$ 9 dyne-sec-cm^{-5} respectively; both $p < .001$) compared to age and arterial pressure matched control subjects. Oscillations of impedance moduli, represented by the difference between maximum and minimum moduli were also significantly increased (101 $\pm$ 3.8 vs. 56 $\pm$ 6.1 dyne-sec-cm^{-5}; $p < .001$) in the MR patients compared to the control subjects. The increased aortic input resistance and characteristic impedance in the MR patients suggests peripheral vasoconstriction and increased aortic stiffness. The larger oscillations in the impedance moduli indicate an increase in pressure and flow wave reflections. These pressure-flow alterations reflect changes in aortic distensibility and arteriolar cross-sectional area resulting in an increased vascular load on the left ventricular in patients with MR.

IDIOPATHIC PROLAPSE OF THE MITRAL VALVE: FOLLOW-UP STUDY OF 136 PATIENTS STUDIED BY ANGIOGRAPHY

Jorge Belardi, MD; Hector Lardani, MD; William Sheldon, MD, FACC; Cleveland Clinic Foundation, Cleveland, Ohio

One hundred thirty-six patients (pts) with angiographically proven prolapse of the mitral valve were followed for 6-15 yrs, mean 9.9 yrs (100% follow-up). Pts with rheumatic or atherosclerotic heart disease were excluded. Mean age was 47, range 9-75 yrs. Ninety-two pts (67.6%) were alive without serious complications, most of them with normal ECGs and competent mitral valve. Six pts (4.45%) died suddenly (age 22-69) all with abnormal ECGs, variable degree of prolapse and only 1 with significant mitral regurgitation (MR). Two pts died with progressive cardiac failure. Mitral valve replacement was performed in 16 pts for severe MR: ruptured chordae was found in 9 pts and endocarditis in 3; 2 pts died within 30 days and 2 later on after surgery. Other nonfatal complications were: endocarditis in 5 pts (3.6%); stroke 6 pts (4.4%); AV block 4 pts (2.9%); recurrent ventricular arrhythmias 5 pts (3.6%); atrial fibrillation 14 pts (10.2%); compensated congestive heart failure 1 pt. These complications occurred in a total of 39 pts (28.9%) in which there was a high incidence of late or pansystolic murmurs instead of isolated clicks, they also had abnormal ECGs and significant MR. The degree of prolapse was similar in the complicated and uncomplicated groups. The majority of pts had a favorable prognosis (67%). However, a significant number of complications occurred with long-term follow-up. Normal ECG, isolated midsystolic clicks and competent mitral valve carries a good prognosis. MR is associated with a high incidence of fatal and nonfatal complications. The degree of prolapse does not have predictive value.

THE EFFECT OF ACUTE AORTIC INSUFFICIENCY ON THE DYNAMICS OF MITRAL VALVE MOTION AND INSTANTANEOUS TRANS-MITRAL FLOW: HEMODYNAMIC MECHANISM FOR THE AUSTIN FLINT MURMUR

Shlomo Laniado, MD, FACC; Edward L. Yellin, PhD; Chaim Yoran, MD, FACC: Joel Strom, MD; Masatsugu Hori, MD; Shlomo Gabbay, MD; Robert W. M. Frater, MD, FACC; Albert Einstein College of Medicine, New York, N.Y.

Acute reversible aortic insufficiency (AI) was induced in 31 experiments in open-chest anesthetized dogs with a basket-tipped catheter introduced through the aortic valve. Controlled regurgitation ranged from 30-70%. Instantaneous trans-mitral flow was registered by a supra annular electromagnetic flow probe. In addition aortic flow, LV, Ao, and LA pressures, and intra cardiac phonocardiogram were recorded. Simultaneously with the hemodynamic measurements, M-mode and 2-D mitral valve echograms were recorded before, during and after AI. With creation of AI, mitral stroke volume decreased immediately 25% (from control of 25$\pm$0.6ml (mean$\pm$S.E.M.) to 18$\pm$0.7ml), but within few beats reached a steady state of 84% of control (21$\pm$0.5ml) ($P<0.001$). Mid-diastolic peak mitral flow velocity (PMFV) dropped instantly to 87% of control ($P<0.01$) however after few beats, during steady state, it increased to surpass control level by 10% ($P<0.05$). Mitral valve echograms revealed that during AI there was a constant decrease (8-15%) in the amplitude of cusp opening. All hemodynamic and echographic changes returned to control levels with the cessation of AI. It is concluded that 1) the increase in PMFV serves to partially compensate for the reduction of total stroke filling volume (and cardiac output) in AI, 2) the increase in PMFV in the presence of reduced valve opening provides a logical hemodynamic explanation for the mechanism of Austin Flint murmur.

AM
LEFT VENTRICULAR MECHANICS IN CHRONIC VALVULAR DISEASE AND TREATMENT OF REFRACTORY LEFT VENTRICULAR FAILURE
10:30-12:00

LEFT VENTRICULAR FUNCTION AND STIFFNESS BEFORE AND AFTER SUCCESSFUL SURGERY FOR MITRAL REGURGITATION.

Florent de Vernejoul, MD ; Françoise Herreman, MD ; Claude Boffety, MD ; Charles Cosma, MD ; François Guerin, MD ; Michel Degeorges, MD. Cochin Hospital, U.E.R. Paris, France.

Left ventricular function (LVF) and stiffness were assessed by hemodynamic and cineangiographic study in 33 patients with chronic mitral regurgitation (MR) before and 14 ± 9 months following valve correction. After surgery, pulmonary and LV end-diastolic pressures decreased ($P < 0.001$), cardiac index increased ($P < 0.01$). LV mass (LVM), end-diastolic volume (EDV), end-systolic volume and stroke volume decreased ($P < 0.001$). LV shape, more spherical before surgery, reverted to normal. Ejection fraction (EF) decreased with no change of mean velocity of circumferential fiber shortening ($\overline{VCF}$). Chamber stiffness reverted to normal ($P < 0.01$), LV myocardidal elasticity (Em) and stiffness constant (K) decreased ($P < 0.01$).

	LVM g/m2	EDV cm3/m2	EF %	$\overline{VCF}$ circ./s	Em g/cm2	K
Pre	141±52	153±42	55±15	1.1±.3	633±279	17.9±1.6
Post	102±39	94±28	49±14	1.0±.3	372±235	16.7±1.9
P	<0.001	<0.001	<0.05	NS	<0.01	<0.01

Surgical correction of MR determined regression of LV dilatation-hypertrophy with normalisation of shape and incomplete improvement of myocardial stiffness. These changes were not associated with improvement of LVF. In conclusion these findings suggest that myocardial alterations fail to regress in spite of successful repair of MR.

SYSTOLIC MECHANICS DURING SURGICAL CORRECTION OF CHRONIC MITRAL REGURGITATION

Calvin Y.H. Wong, MD; Henry M. Spotnitz, MD, FACC; Columbia University College of Physicians and Surgeons, New York, N.Y.

M-mode and 2-D echocardiography were combined with LV pressure-flow data to analyze systolic mechanics during valve replacement for chronic mitral regurgitation (CMR) using a changing volume spherical model. Preop RAO angiography provided LV mass and a regression correlating M-mode diameter with LVEDV (r=.82). Flow-velocity data was calibrated by thermal dilution.

Both M-mode (n=6) and 2-D (n=6) echo reveal large decreases in early postoperative shortening fraction (SF) (-24±17(SD)% p<.01 M-mode, -20±18% p<.03 2-D) which are significantly different from small changes in control populations (+7±10% n=25 M-mode, -1±14% n=22 2-D). In 5 CMR patients, the integral of LV wall stress increases significantly after valve replacement (26±6 g/cm sq. preop vs. 36±7 postop, p<.02), which may produce decreased SF. Compared with 5 patients undergoing coronary revascularization. LVEDV (437±213 vs. 128±33 ml) and mass (521±190 vs. 195±42 g) are increased in CMR (p<.02). Peak fiber shortening velocity (.21±.08 vs. .48±18 circ/sec, p<.02) and SF are decreased. But 14 additional hemodynamic and structural parameters are not significantly different. These results emphasize the derangement of preoperative LV function in CMR and highlight deterioration of volume-related vs. pressure-related parameters of LV performance.

NONINVASIVE DETERMINATION OF THE ENDSYSTOLIC PRESSURE VOLUME RELATION IN PATIENTS WITH AORTIC REGURGITATION

Gerhard Schuler, Klaus v. Olshausen, Helmut Mehmel, Franz Schwarz, HJ Hermann, Wolfgang Kübler, FACC Medizinische Universitätsklinik, Heidelberg, Germany

Previous reports indicated that the left ventricular endsystolic pressure volume relation (ESPV) is a sensitive parameter of myocardial contractility independent of preload and afterload. In order to determine LV-ESPV noninvasively we measured changes in endsystolic volume by gated radionuclide angiography (RNA) in 14 patients (pt) with chronic aortic regurgitation and in 9 normals. Peak systolic pressure was measured by automated cuff and substituted for endsystolic pressure. Variations in blood pressure were achieved by i.v.methoxamine, while heart rate was kept within narrow limits by atropine. In order to detect stress induced LV dysfunction both groups also underwent maximal graded bicycle exercise (EX) while changes in LV ejection fraction were determined by RNA. In normals the slope k of the ESPV ranged from 4 to 8 and LV ejection fraction (EF) rose by more than 5% during EX. In pts with aortic regurgitation two subgroups could be identified. GROUP A (n=8): there was marked depression of k ($k < 3$) despite a normal resting EF; these pts also developed LV-dysfunction during EX (rise in LV-EF < 5%). GROUP B (n=6): the slope k fell within the normal range (n=4) or was only marginally depressed ($4 > k > 3$; n=2); LV reserve proved to be normal in these pts (rise in LV-EF > 5%). All pts were NYHA class I or II. We conclude: the slope of the ESPV is readily determined by RNA and cuff pressure measurements; it is highly sensitive to early impairment of myocardial contractility and correlates well with stress induced LV dysfunction in pts with aortic regurgitation whose resting ejection fraction is still within the normal range.

POTENTIAL VALUE OF ORAL β_2 ADRENOCEPTOR AGONISTS IN LEFT VENTRICULAR FAILURE.

Timmis A.D.., Bergman,G., Atkinson L., Monaghan M., Jewitt D.E.
Department of Cardiology, King's College Hospital, London.

This study was designed to assess the haemodynamic effects and metabolic consequences of β_2 adrenoceptor agonists in left ventricular failure. IO patients with severe left ventricular dysfunction secondary to coronary artery disease received an oral dose of pirbuterol 20mg or salbutamol 6mg and haemodynamic and metabolic effects were measured 30, 60 and 90 minutes later.

After 30 minutes systemic vascular resistance fell. from 23 to 19 units ($p<0.01$) and cardiac output increased from 3.7 to 4.5 L/min ($p<0.01$) although mean arterial blood pressure remained unchanged. Left ventricular dp/dt max increased from 921 to 1411 mmHg/sec despite a fall in pulmonary artery diastolic pressure from 19 to 17 mmHg ($p<0.05$). Myocardial blood flow (152 to 162 ml/min) and oxygen uptake (15.2 to 15.0 ml/min) did not change significantly. Myocardial extraction of lactate, glucose and free fatty acids remained unchanged. These effects were maintained for 90 minutes and we observed no important differences in the responses to pirbuterol or salbutamol.

These results indicate that in patients with left ventricular failure β_2 adrenoceptor agonists improve myocardial performance by a combination of afterload reduction and positive ionotropism, and this effect is achieved at little net metabolic cost to the ischaemic myocardium.

HEMODYNAMIC EFFECTS OF A NEW BETA$_1$-AGONIST (PRENALTEROL) IN PATIENTS WITH CONGESTIVE HEART FAILURE

Raimund Erbel, MD, Jürgen Meyer, MD, Peter Schweizer, MD, Heinz Lambertz, MD, Wolfram Voelker,cand med, Sven Effert, MD, Department of Internal Medicine I, Rheinisch-Westfälische Technische Hochschule, Aachen, Federal Republic of Germany

Beta$_1$-stimulation is a new therapeutic approach in severe congestive heart failure. The hemodynamic effects of a new beta$_1$-agonist - prenalterol (P) - were analysed in Patients with chronic heart failure due to coronary artery disease (n = 6) and congestive cardiomyopathy (n = 6). All patients were only on digitalis and diuretica and were in class III - IV NYHA. Left ventricular systolic and end-diastolic pressure (LVSP, LVEDP) were obtained with micro manometer before (C) and 20 min after infusion of 12 mg P. Peak (+) and (−) dp/dt as well as the time constant (T) of isovolumic exponential pressure decline were determined. Cardiac index (CJ) was received by thermodilution techniques, LV volumes and ejection fraction (EF) by cineangiocardiography. All values (± sem) were determined at a constant heart rate of 100 beats/min before and after P by atrial stimulation. LVSP remained constant

	LVEDP mm Hg	+dp/dt mm Hg/sec	-dp/dt mm Hg/sec	T msec	CJ l/min x m^2	EF %
C	21,4 ± 3,4	1164 ±111	1057 ± 85	62,4 ±4,9	3,6 ± 0,3	24 ± 3
P	14,9 ± 3,2	1587 ± 190	1268 ±118	44,5 ±5,9	4,2 ±0,4	30 ±4
p	< 0,001	< 0,005	< 0,005	< 0,005	< 0,002	< 0,002

Simultaneous analysis of pressure and volume revealed, that LV power increased from 6,5 ± 0,8 to 7,8 ± 0,9 W ($p < 0,02$) and LV work from 1042 ±129 to 1200 ± 145 Wsec ($p < 0,02$). LV wall stress remained constant 32,6 ± 3,0 and 29,4 ±2,2 kPa. Diastolic pressure-volume analysis showed that LV ventricular compliance decreased from 22,1 ±4,7 to 13,4 ± 1,7 x 10^{-3} ml^{-1} and myocardial compliance from 70,8 ± 14,2 to 47,2 ± 5,1 x 10^{-3} cm^{-1}.

We conclude, that prenalterol increased LV contractility and relaxation, improved LV ejection and LV compliance, characteristic phenomena of beta$_1$-agonists. LV function curve was shifted to the left and upwards. The improvement of LV function underlines that beta$_1$-stimulation is a promising new approach for treatment of severe congestive heart failure.

LONG TERM EFFECT OF ORAL AMRINONE IN HEART FAILURE: IMPROVEMENT IN EXERCISE PERFORMANCE DESPITE DECLINING LEFT VENTRICULAR PUMP FUNCTION

Lewis Siegel, MD; Joel Strom, MD; Eugene Fein, MD; John Wexler, MD; Carol Maskin, MD; Thierry LeJemtel, MD; Edmund Sonnenblick, MD, FACC, Albert Einstein College of Medicine, Bronx, New York.

Thirteen patients (pts) with severe congestive heart failure (NYHA Class IV), demonstrating initial hemodynamic improvement with Amrinone therapy, were serially evaluated with M-mode echocardiography (ECHO), multigated radionuclide ejection fraction (EF), and Naughton protocol treadmill exercise testing, to evaluate the chronic effects of Amrinone on LV performance, and functional capacity. Pts were observed for an average follow-up period of 8 months (mos), range (3-17 mos). Baseline studies revealed a mean ECHO LV end diastolic diameter (EDD) of 7.2±0.2 cm, EF 14±1.4%, and exercise capacity of 4.4±1.0 minutes (min). Within 3 mos, a sustained improvement in exercise capacity 6.6±2.2 min, was demonstrated despite a progressive increase in LVEDD, 7.5±0.3 cm. During a late follow-up period (3 to 17 mos), there was a further increase in LVEDD, 7.8±0.3 cm, however, functional capacity continued to improve, 11.4±1.3 min. EF at 3 mos, and > 3 mos. were 18.3±2% and 12±2.8%, and not significantly different. The data suggests that with Amrinone therapy, there is an initial and sustained improvement in functional capacity despite the progression of underlying LV disease, evidenced by the increasing LVEDD. A persistent inotropic effect may explain the maintenance of an improved stroke volume and net LV performance.

THE ATRIO-VENTRICULAR NODE
10:30-12:00

AUTONOMIC MODULATION OF A-V NODAL CONDUCTION IN CONSCIOUS DOGS.

John X. Thomas, Jr., Ph.D. and Walter C. Randall, Ph.D., FACC, Loyola University Medical Center, Maywood, Illinois

The autonomic nervous system can exert considerable influence on the conduction properties of the A-V node. The purpose of these experiments was to evaluate the role of this innervation under conditions when autonomic tone is minimal. The maximal atrial pacing rate with 1:1 A-V conduction (Rmax) was determined in 10 unanesthetized dogs which had been previously instrumented with 2 bipolar right atrial electrodes. Each dog was paced from 80-400 beats/min in a random sequence while recording a Lead II EKG. Resting heart rate of all dogs was 95±2. Rmax under control conditions was 131±6. After propranolol (Prp, 1.0 mg/kg, IV) Rmax was reduced to 118±11 ($p=.022$). After atropine (A, 0.2 mg/kg, IV) Rmax was increased to 344±10 ($p<.001$). After both A and Prp Rmax was 316±10 (different, $p<.05$, from A group). Rmax was also determined in 6 additional dogs which had previously undergone a surgical denervation of the A-V nodal region and ventricles. Rmax was 293±7 (not different, $p=0.21$, from Rmax in control dogs after A and Prp). In another group of dogs (n=3), heart rates were monitored for 24 hrs via a Holter monitor. After the resting heart rate was determined (81±3) each dog was paced at 10 beats higher than its resting rate via a Medtronics demand pacemaker. During the 24 hr period there were bouts of A-V block, which were not abolished by concommittant treatment with P. These data indicate that in conscious dogs with surgically denervated or pharmacologically blocked A-V nodes, impulses can be conducted at very rapid rates. Blockade of the sympathetics in neurally intact dogs with Prp reduced Rmax slightly, however the effects of parasympathetic blockade were much more prominent. Resting tone is predominantly parasympathetic.

CLOSED CHEST PERMANENT ATRIOVENTRICULAR BLOCK IN DOGS: TECHNIQUE AND ANATOMIC CHANGES

R. Gonzalez, MD; M. Scheinman, MD, FACC; W. Margaretten, MD; S. Bharati, MD; M. Lev, MD, FACC; University of California, San Francisco, Ca.

Complete atrioventricular block (AVB) was produced in 9 consecutive dogs using a direct current (D/C) defibrillator and an electrode catheter in which 2/3 of the electrode surface was insulated. The catheter was inserted by vein and positioned to record the His bundle deflection. D/C shocks of 140 joules were delivered from the catheter electrode to a plate behind the back. Complete AVB was induced with one shock in 6 dogs and with 2-4 shocks in 3. Complete AVB persisted for 3 months prior to sacrifice. The QRS duration was prolonged (≥120 msec) and a His bundle potential could not be recorded from either right or left heart electrode catheters. The mean spontaneous ventricular cycle length (1575±350 msec) decreased after exercise (1230±217) ($p<0.01$), increased after intravenous (0.2 mg/kg) propranolol (1710±409) ($p<0.05$), but did not change after intravenous (0.04 mg/kg) atropine. The change in rate after exercise was abolished by propranolol. No gross myocardial or valvular damage was present and histologic studies of the AV conduction system were completed in 5 dogs. In dogs receiving a single shock, less severe degenerative, fibrotic and necrotic changes were observed in the AV node, its approaches and in the penetrating and branching portions of the His bundle than when multiple shocks were required. We describe a simple technique for production of chronic AVB, the emerging pacemaker is fascicular or ventricular and modulated by changes in sympathetic tone. The absence of valvular or myocardial damage provides an excellent animal model for physiologic experiments and may be of value in patients with drug resistant supraventricular tachycardia.

MEMBRANE CURRENT SYSTEMS IN THE RABBIT ATRIOVENTRICULAR NODE. THE FIRST VOLTAGE CLAMP STUDY

Masao Nishimura, MD; Shinichiro Kokubun, MD; Akinori Noma, MD; Hiroshi Irisawa, MD; Yoshio Watanabe, MD, FACC, Cardiovascular Institute, Fujita Gakuen University, Toyoake, Aichi, Japan

To investigate the membrane current systems in the rabbit atrioventricular node (AVN), small preparations with final dimensions of 0.2 x 0.2 x 0.2mm were dissected from the middle portion of AVN. These preparations generally showed spontaneous action potentials with configurations quite similar to those of N cells. Voltage clamp was conducted with double microelectrode techniques as used by Noma and Irisawa on sinoatrial node (SAN). During voltage clamp, the membrane potential was usually held at -40mV, where the steady net current was about 0. A transient inward current (TIC) was recorded on depolarization between -40 and +35mV, becoming maximal at around -10mV. The TIC reached its peak 5-10ms after the onset of the test pulse, and was inactivated with a time constant of 15-30ms. This current was identified as the slow inward current since it was insensitive to tetrodotoxin and abolished by D-600. The depolarization-induced TIC was followed by a slow increase in the outward current, which, on clamping back to the holding potential, showed a gradual decay with a time constant of 189 ± 24ms (n=6). The reversal potential, obtained at 10 and 20mM K^+ Tyrode, decreased with a slope of 61mV for a 10-fold increase in $[K]_o$ (n=4), indicating this outward current to be carried by K^+. On hyperpolarization from -40 to -70 and -80mV, a large inward current was observed with a time constant of 3s. These findings suggest that AVN possesses membrane current systems quite similar to those in SAN, and that a common ionic mechanism underlies automaticity and slow conduction in these two nodal structures in the heart.

ADDITIONAL EVIDENCE FOR ADENOSINE MEDIATION OF A-V CONDUCTION DISTURBANCES IN CANINE MYOCARDIUM.

Luiz Belardinelli, MD; Elizabeth Mattos, MD; Fernando A. Lucchese, MD; Robert M. Berne, MD. Instituto de Cardiologia RS, Porto Alegre, Brasil, Dept. of Physiol., Univ. of Virginia, Charlottesville, VA.

We reported that the A-V conduction delay caused by adenosine (Ado) or hypoxia is markedly attenuated by 10^{-5}M Aminophylline (Am), an Ado competitive antagonist. In additional studies on 22 anesthetized dogs A-V conduction time (AVCT) and AH and HV intervals, His-bundle, atrial and ventricular surface electrograms were recorded. The A-V node artery (AVNA) was cannulated for selective infusion of drugs into the A-V node region. In 16 of the dogs, Ado (as a 1 ml-bolus of 10-1000µg) transiently increased the AVCT due solely to a lengthening of the AH interval. Ado at 10µg and 100µg dose prolonged the AH interval from a control value of 55±5msec to 80±5msec and 105±10msec, respectively. At 1000µg, Ado produced 2nd degree A-V block. Duration of the transient increase of AVCT was also dose-dependent. Pretreatment with dipyridamole (250µg/kg), an inhibitor of Ado uptake, potentiated the effects of Ado in magnitude and duration, whereas Am attenuated the effects of Ado. In 6 dogs, within 10 min after AVNA cannulation, the AH (but not HV) interval was prolonged, and, 2nd degree A-V block occurred. Injection of Am (5 mg/kg IV) or of theophylline (100 or 1000µg) into the AVNA rapidly reversed the A-V block. Upon washout of the drugs the A-V block reappeared. Thus, if the blood supply to the A-V node is sufficiently impaired by AVNA occlusion release of endogenous Ado could explain the observed A-V block; reversal of the block by methyl xanthines supports this suggestion. We conclude that endogenously released Ado may account for a major fraction of the acute A-V conduction disturbance associated with myocardial ischemia.

ELECTROPHYSIOLOGICAL MECHANISMS OF AV CONDUCTION IN RESPONSE TO ATRIAL FIBRILLATION REVEALED BY MULTIPLE SIMULTANEOUS EXTRACELLULAR AND INTRACELLULAR RECORDINGS

Todor Mazgalev, PhD, Leonard S. Dreifus, MD, FACC, John Bianchi, Eric L. Michelson, MD, FACC, Thomas Jefferson University and Lankenau Hospital, Philadelphia, PA

Atrial fibrillation (AF) was induced in 20 superfused rabbit atrial-AV nodal (AVN) preparations in which simultaneous extracellular bipolar electrograms were recorded from the crista terminalis (CT), interatrial septum (IAS) and His bundle (H) along with microelectrode action potential recordings from cells in the AN, N and NH regions to map AVN activation. Effective engagement of the AVN with optimal propagation to the N region was critically dependent on both the timing and interaction of the random inputs arriving from the CT and IAS regions; whereas cancellation and fractionation of the random inputs resulted in concealed and manifest block. Conduction through the AN and N region was also influenced by the degree of inhomogeneous activation of fibers forming the predominant conduction pathway. Fragmentation of the wavefront of upstream fibers was responsible for multiple graded responses in the N region rather than electrotonic spread or reentry mechanisms. Engagement of the NH region always produced a 1:1 NH to H relationship. Conclusions: 1) Activation of the AN region occurs randomly via inputs from both the CT and/or IAS in AF; 2) Effective engagement of the AN and N regions is both time and voltage dependent so that downstream propagation is critically related to the degree of synchronous activation of both AN and consequently N fibers; 3) Fractionation and cancellation of wavefronts rather than reentry mechanisms within the AVN can account for decrement and inhomogeneous conduction in response to AF.

DIFFERENCES IN RESPONSIVENESS OF SA AND AV NODE TO VAGAL STIMULATION.

Jerod M. Loeb, PhD; Daniel P. Dalton, BS; John M. Moran, MD. Northwestern University Medical School, Chicago, Illinois 60611.

It has recently been reported that SA node muscarinic receptors desensitize following prolonged vagal activation (VA). This study was directed toward a more clear characterization of vagally-induced desensitization at the SA node and also sought to determine whether these findings could be extended further to AV nodal conduction. Autonomically decentralized, chloralose anesthetized dogs (n=15) were instrumented to record ECG, arterial pressure and electrograms from SA node, RA, RV and His bundle. Right cervical VA for 60 sec increased initial cycle length (CL) 221% followed by a gradual recovery toward control; AH interval was maintained at 37% above control. VA on the left side increased initial CL 45% with less reversion of CL toward control; however, AH interval was maintained at 51% above control. Atrial drive increased control AH 11% and AH interval during right VA 81%, but AH prolongation was still maintained throughout the stimulation period. To rule out acetylcholine (ACh) depletion, ACh was administered before and during VA. While control CL and AH interval were lengthened by ACh, no significant CL increases occurred when ACh was given during VA; however, AH interval did prolong. Propranolol increased control CL 26% and control AH 12% but did not alter the relationship between VA and CL or AH interval. These data show that the negative chronotropic effect of ACh at the SA node is indeed diminished upon prolonged VA while the negative dromotropic effect upon AV nodal conduction remains unaltered. These results cannot be explained by innervation density, ACh depletion or catecholamine release but may reflect differences in cholinesterase activity or muscarinic receptor behavior at the SA and AV node.

LABETALOL THERAPY IN ANGINA PECTORIS AND SYSTEMIC HYPERTENSION: EFFECTS OF COMBINED ALPHA-BETA ADRENERGIC BLOCKADE

William H.Frishman, MD,FACC; Marc Kirschner, MD; Joel Strom, MD; Neal Klein, MD; Stanley Halprin, MD; Susan Goldner; Thierry LeJemtel, MD; Marcia Poland, BA; Michael Kram, BA; Roger Strair, PhD; Edmund H. Sonnenblick, MD, FACC, Albert Einstein College of Medicine, Bronx, N.Y.

The effects of oral labetalol (L), an alpha-beta adrenoceptor blocker, were evaluated in 10 patients (pts) with angina pectoris and hypertension. After 3 weeks of placebo (pl), increasing doses of L (300-1,200 mg/day) were given over 4 weeks followed by a rapid drug withdrawal phase. Anginal attack frequency and exercise tolerance (treadmill) were measured; also assessed were non-invasive indices of LV function (echo, systolic time intervals), plasma renin activity (PRA) and platelet function (aggregability). Compared to pl, the frequency of angina attacks/week was reduced with L; exercise time increased from 4.1±1.0 to 6.3±0.5 min, $p<0.01$. L lowered resting supine (sup) and standing blood pressure (BP) and heart rate (HR) in all pts; sup systolic BP 154.5±6.1 to 121.5±7.9 mmHg, $p<0.001$, sup diastolic BP 103.6±1.6 to 87.1±2.1 mmHg, $p<0.01$, sup HR 76.8±4.7 to 63.9±3.5 beats/min, $p<0.05$. The increments in systolic BP with exercise were significantly blunted, $p<0.01$, while HR increments were not affected. There was a significant reduction in resting HRxBP and an inhibition of HRxBP increments with exercise. At comparable exercise time, ECG ST segment depressions were less with L compared to pl, $p<0.05$. Compared to pl there were no effects of L on platelet function and on non-invasive indices of LV function. Pts with elevated PRA (n=3) demonstrated a marked reduction after L; pts (n=7) with normal or low PRA were not affected by L. No "rebound" effects were seen following L withdrawal. Combined alpha-beta adrenergic blockade with L is effective for relieving angina symptoms, improving exercise tolerance, and reducing elevated BP.

REDUCTION OF MYOCARDIAL ISCHEMIA BY BALANCED ALPHA AND BETA BLOCKADE WITH LABETALOL

Dietmar H. Glogar, M.D.; Robert A. Kloner, M.D., Ph.D.; Harvard Med. School/Peter B. Brigham Hosp., Boston, MA

It is known that beta blockade decreases blood flow to ischemic myocardium, but it is unknown whether this effect, which may be related to unopposed alpha stimulation, can be counteracted by additional alpha blockade. Labetalol (LAB) offers the opportunity to study both types of blockade since it has been shown to block predominantly beta receptors at 0.5 mg/kg (LAB I) and both alpha and beta receptors at 5.0 mg/kg (LAB II). Therefore, 28 anesthetized dogs received left anterior descending coronary artery occlusions. After 15 min of occlusion 7 dogs received a 5 min bolus of LAB I, 7 dogs LAB II, 14 control dogs normal saline (NS). The myocardium at risk of necrosis (MR) was determined before the intervention by an autoradiographic technique (MR I) and also at 6 hours of occlusion by Thioflavin S (MR II). Infarct size (IS) in percent left ventricle below occlusion (%LV) was determined by triphenyltetrazolium chloride stain. Regional myocardial blood flow (RMBF) was measured by microspheres before and 15 min following therapy. In LAB II vs. NS IS (%LV) was smaller (24 ± 3 vs 30 ± 2 respectively, $p<0.05$), while MR I (%LV) was not different (30 ± 2 vs 31 ± 2, p=n.s.). Only 79 ± 6% of MR I were infarcted in LAB II treated dogs vs 98 ± 4% in NS ($p<0.01$). Furthermore, RMBF immediately adjacent to the infarct increased from 0.61 ± 0.05 ml/min/g before to 0.80 ± 0.07 ml/min/g following treatment ($p<0.05$) leading to a reduction of the MR. In LAB I RMBF was decreased by the intervention from 0.60 ± 0.07 ml/min/g to 0.48 ± 0.04 ml/min/g, while no significant effect on IS was observed. Thus, the combination of alpha and beta blockade achieved by high dose labetalol (LAB II) improved coronary blood flow to the ischemic myocardium. Also, LAB decreased IS. This indicates that balanced alpha and beta blockade reached with high dose LAB may overcome secondary vasoconstriction observed in predominant beta receptor blockade.

THE EFFECTS OF MODERATE AND HIGH DOSE PROPRANOLOL ON VENTRICULAR FUNCTION IN PATIENTS WITH CORONARY ARTERY DISEASE

Kenneth G. Morris, MD, Sebastian T. Palmeri, MD, R. Edward Coleman, MD, David Shand, MD, Frederick R. Cobb, MD, Duke University and VA Medical Centers, Durham, North Carolina

Effects of moderate(160 mg/d) and high dose(480 mg/d) propranolol(P) on rest(R) and exercise(Ex) left ventricular(LV) function were determined in 14 patients with symptomatic CAD. LV function was measured by multigated radionuclide angiography(RNA) in the upright position at control and after 2 weeks on each dose. Measurements included heart rate-pressure product($R\cdot P$), ejection fraction(EF), wall motion index(WMI) determined from 3 regions graded 0-5 for normal, mild or severe hypokinesis, akinesis or dyskinesis and plasma P levels. The following lists $\bar{X}$ data ± SD at rest. *=$p < .05$ vs cont, †=$p < .05$ vs P-160.

	$R\cdot P\times10^2$	EF%	WMI	Plasma P ng/ml
Cont	102±31	57±4	1.9±1.4	
P-160	76±18*	58±6	1.4±1.8	69±41
P-480	69±15*	59±6	.86±1.0	288±136†

The following list $\bar{X}$ data and no. patients with ↓ST and chest pain(CP) at control maximum workload.

	$R\cdot P\times10^2$	EF%	ΔEF%	WMI	↓ST	CP
Cont	214±60	52±8	-5.0±.8	5.3±1.5	12	11
P-160	146±37*	56±7	-2.6±.6	3.3±2.1*	7*	5*
P-480	139±36*	57±8	-2.1±.6	2.9±2.0*	1*†	1*†

These data indicate that at pretreatment maximum workload, P-160 reduces regional dysfunction, $R\cdot P$, ↓ST and CP but does not effect global EF; P-480 did not further improve Ex LV function or reduce $R\cdot P$ despite further reduction in ↓ST and CP.

PERSISTANT MYOCARDIAL PROPANOLOL LEVELS IN MAN

John R. Plachetka, Pharm.D.; Neal W. Salomon,M.D.; Jack G. Copeland, M.D., University of Arizona, Tucson, Arizona

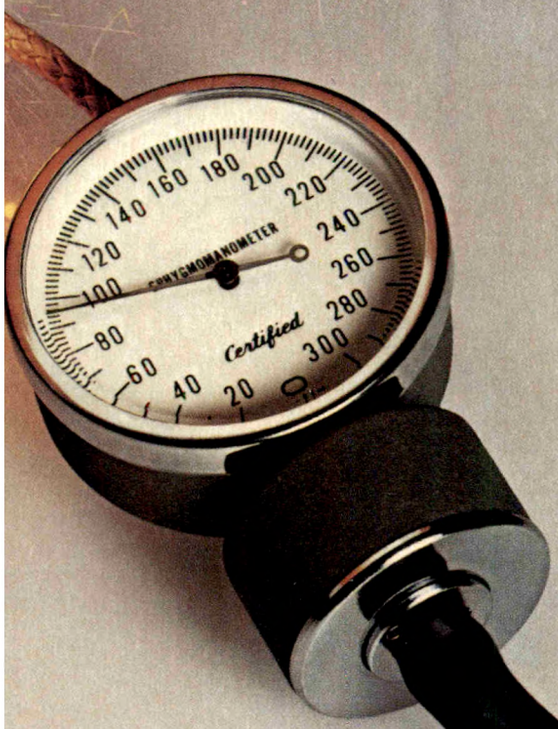
The physiologic effects of propanolol (P) are present after chronic oral dosing even when plasma levels are unmeasurable. The reason for this prolonged activity is unknown but may be related to large amounts of P remaining in the target organs. Since there is little information about the relationship between plasma and heart P concentrations in man,we obtained simultaneous plasma and right atrial tissue samples prior to cardiopulmonary bypass from 19 patients maintained on chronic oral P for angina. 14 pts (group I) received 0.1mg/kg P I.V. 1-2 hrs. prior to sampling and 5 patients (group II) did not get I.V. P but received their last oral dose 10-15 hrs before sampling. P in tissue homogenate extracts and plasma was assayed by fluorimetry.

There is an excellent correlation between tissue and plasma concentrations of P in group I ($r=0.943$, $p<0.001$) and group II ($r=0.992$, $p<0.001$). However, the tissue to plasma ratio was higher in group II (13.1 ± 1.73sd) than in group I (9.4 ± 3.82sd) ($p<0.05$). As the plasma levels were nearly identical, the difference was due to higher tissue levels in group II. The acute I.V. administration of P was well tolerated by all patients but one who required atropine for bradycardia.

The concentration of propanolol in heart tissue is approximately 10 times greater than that in plasma. Assuming the first-order elimination rates of P from tissue and plasma are equal, P in tissue will be present in detectable quantities twice as long as P in plasma. The prolonged action of P may be due to sufficiently high P concentrations at the myocardial beta-receptor to produce blockade even though plasma levels are undetectable.

New evidence is in:

Treatment of mild hypertension can save lives



Even among patients with DBP in the low 90s systematic therapy significantly reduced mortality:

- Of nearly 11,000 hypertensives identified by the Hypertension Detection and Follow-up Program, slightly more than 70% had mild hypertension (DBP 90-104 mm. Hg).[1]
- Half were given systematic and aggressive care in HDFP centers; half were referred to customary sources of medical care.
- After 5 years, HDFP found that effective treatment of mild hypertension may reduce premature deaths by 20%.[1]
- As part of HDFP's systematic treatment and follow-up program, the primary step-1 agent was chlorthalidone: Hygroton®.[2]

The primary agent used by the HDFP in an effective low dose

Hygroton® 25 mg. one a day
(chlorthalidone USP)

Because there's nothing mild about mild hypertension

BRIEF SUMMARY

Indications: Hypertension, adjunctive therapy in edema. **Contraindications:** Anuria, hypersensitivity to chlorthalidone or other sulfonamide-derived drugs. **Warnings:** Should be used with caution in severe renal disease, impaired hepatic function or progressive liver disease. May add to or potentiate the action of other antihypertensive drugs. Sensitivity reactions may occur in patients with a history of allergy or bronchial asthma. There is a possibility of exacerbation or activation of systemic lupus erythematosus with thiazides, which are related to chlorthalidone. This has not been reported with chlorthalidone. Thiazides cross the placental barrier and appear in cord blood. Use in pregnant women requires that the anticipated benefits of the drug be weighed against possible hazards to the fetus. These hazards include fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. In nursing mothers, thiazides cross the placental barrier and appear in breast milk. If use of the drug is essential, the patient should stop nursing.
Precautions: Periodic determination of serum electrolytes to detect possible electrolyte imbalance should be performed at appropriate intervals. All patients receiving chlorthalidone should be observed for clinical signs of fluid or electrolyte imbalance; namely, hyponatremia, hypochloremic alkalosis, and hypokalemia. Serum and urine electrolyte determinations are particularly important when the patient is vomiting excessively or receiving parenteral fluids. Medication such as digitalis may also influence serum electrolytes. Hypokalemia may develop with chlorthalidone as with any other potent diuretic, especially with brisk diuresis, when severe cirrhosis is present, or during concomitant use of corticosteroids or ACTH. Interference with adequate oral electrolyte intake will also contribute to hypokalemia. Digitalis therapy may exaggerate metabolic effects of hypokalemia especially with reference to myocardial activity. Any chloride deficit is generally mild and usually does not require specific treatment except under extraordinary circumstances (as in liver disease or renal disease). Dilutional hyponatremia may occur in edematous patients in hot weather. Hyperuricemia may occur or gout be precipitated in certain patients. Insulin requirements in diabetic patients may be increased, decreased, or unchanged and latent diabetes mellitus may become manifest. Chlorthalidone and related drugs may increase the responsiveness to tubocurarine. The antihypertensive effects of the drug may be enhanced in the postsympathectomy patient. Chlorthalidone and related drugs may decrease arterial responsiveness to norepinephrine. If progressive renal impairment becomes evident, as indicated by a rising nonprotein nitrogen or blood urea nitrogen, a careful reappraisal of therapy is necessary with consideration given to withholding or discontinuing diuretic therapy. Chlorthalidone and related drugs may decrease serum PBI levels without signs of thyroid disturbance. **Adverse Reactions:** Anorexia, gastric irritation, nausea, vomiting, cramping, diarrhea, constipation, jaundice (intrahepatic cholestatic jaundice), pancreatitis; dizziness, vertigo, paresthesias, headache, xanthopsia; leukopenia, agranulocytosis, thrombocytopenia, aplastic anemia; purpura, photosensitivity, rash, urticaria, necrotizing angiitis (vasculitis) (cutaneous vasculitis), Lyell's syndrome (toxic epidermal necrolysis). Orthostatic hypotension may occur and may be aggravated by alcohol, barbiturates or narcotics. Other adverse reactions include hyperglycemia, glycosuria, hyperuricemia, muscle spasm, weakness, restlessness, impotence. Whenever adverse reactions are moderate or severe, chlorthalidone dosage should be reduced or therapy withdrawn.
Usual Dose: One tablet daily. **How Supplied:** Tablets—100 mg. (white, scored), 50 mg. (aqua) in bottles of 100, 1000 and 5000; 25 mg. (peach) in bottles of 100 and 1000; unit-dose blister packs, boxes of 100 (10 x 10 strips).

THE·NEW MICROTHIN™-P2... GUARANTEED SENSING

MICROTHIN-P2's sensing is so exceptional that, whenever you implant a MICROTHIN-P2 with a CPI® Porous Tip Lead, it is guaranteed. If any sensing difficulties develop, you'll receive immediate full credit for the MICROTHIN-P2.

CPI has recognized that efficient sensing is of paramount importance, and we've responded to that need with the MICROTHIN-P2. In fact, MICROTHIN-P2 addresses *all* the issues that are of prime importance in cardiac pacing:

- Proven reliability*
- The most useful programmable features - rate and energy output
- Superior sensing
- Lifetime warranty**
- Small size for patient comfort
- Easy, safe follow-up

Eight years of CPI experience prove that pacing can evolve... advance...become simpler yet superior. That's MICROTHIN-P2. It is the simple, effective solution for the majority of your pacemaker patients.

For single-rate demand pacing, ask your sales representative about MICROTHIN-D2.

*For a copy of CPI's "Seven Years of Reliability" report, contact your sales representative.

**The lifetime warranty option is not available in all countries. Contact your sales representative for full warranty information for your area.

Energy for Life

IREX

Systems that break the ultrasound barriers.

x is making breakthroughs in echocardi-
raphy. Technological breakthroughs.
eakthroughs that provide crisper images.
re diagnostic capability. Greater flexi-
ty. And all at breakthrough prices.

Phased Array Real Time Imaging System

amically focused 2-D sector scanner featuring unique 32 channel
ormance. Plus two sector-derived M-modes and a totally inde-
dent M-mode. Compact, electronically steered, lightweight trans-
ers. Optional heart sound/pulse and respiration module. Integral,
anced design Sony® Beta format video cassette recorder. Simulta-
us 2-D and M-mode black and white hard copy. And more.

Cardio 80® Graphics Analyzer

active quantitative analysis of two-dimensional images, M-mode
ocardiograms and other cardiodiagnostic data. 2-D analysis from
lay screen video or hard copy. Immediate printout of results. User
rammable for analysis of research and special applications data.
more.

Here's how Irex breaks the barrier

Technology. Innovative recording and display systems specifically designed for the cardiologist. Flexible, highly sensitive echo amplifier. Dynamically focused phased array. Ultrahigh resolution. Microprocessor control. State-of-the art, phased array transducers. Software updating. High-speed digital scan conversion. All Ire designed. All Irex built. So you get leading-edg performance for improved diagnostic images.

Versatility. Broadest range of cardiac diagnostic capabilities in each Irex system. Highly flexible signal processing controls. So you can perform and analyze the study you want, the way you want to do it.

Mobility. Compact, durable systems that go where you need them, when you need them.

Commitment. The Irex commitment assures quality, reliability, continuing attention; prompt service from factory-trained Irex representatives; on-site training. So you get the most out o your Irex system.

Value. Irex systems give you features and sophistication that would cost you thousands more elsewhere.

Breakthrough technology at breakthrough pric is what Irex echocardiography is all about. Return the coupon today for more ultra-exciting information.

If you can't hold
the patient,
you can't hold
the pressure
Sculpture representing the
alpha central action* of Combipres®

Alpha... hold the pressure

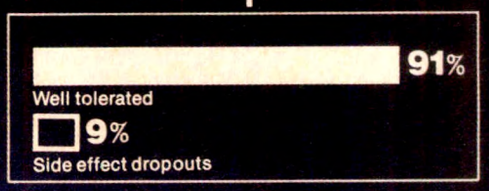
- central control of blood pressure*
- low incidence of impotence, depression, orthostatic hypotension**
- most common side effects are dry mouth, drowsiness and sedation, which generally tend to diminish with time. As with other agents containing diuretics, hypokalemia, hyperuricemia, and hyperglycemia may occur.

*Central alpha-adrenergic stimulation decreases sympathetic outflow from the brain, as shown in animal studies.

**Orthostatic hypotension has been reported with chlorthalidone and may be potentiated when chlorthalidone is combined with alcohol, barbiturates, or narcotics.

plus... hold the patient

91% compliance†



†Of 484 patients in 16 clinical trials, only 9% definitely or probably dropped out due to side effects.[1]

[1] Data on file, Boehringer Ingelheim Ltd.

Please see brief summary on last page for warnings, precautions, and adverse reactions.

Combipres is not indicated for initial therapy. It is for patients responsive to its components given separately in equivalent dosages.

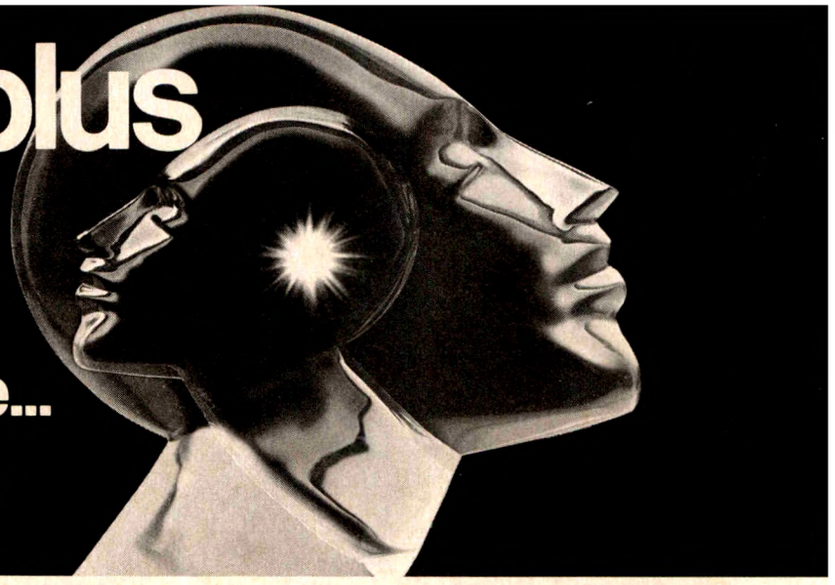
Combipres®

Each tablet contains: Catapres® (clonidine HCl) 0.1 or 0.2 mg, and chlorthalidone, 15 mg

.1 and .2

Hypertension

Alpha...plus



hold the pressure... hold the patient...

Combipres® .1 and .2

Each tablet contains: Catapres® (clonidine HCl) 0.1 or 0.2 mg, and chlorthalidone, 15 mg

Warning: This fixed combination drug is not indicated for initial therapy of hypertension. Hypertension requires therapy titrated to the individual patient. If the fixed combination represents the dosage so determined, its use may be more convenient in patient management. The treatment of hypertension is not static, but must be reevaluated as conditions in each patient warrant.

Indication: The drug is indicated in the treatment of hypertension (see box warning).

Contraindications: Patients with known hypersensitivity to chlorthalidone and patients with severe renal or hepatic diseases.

Warnings: Tolerance may develop in some instances necessitating a reevaluation of therapy.

Usage in Pregnancy: In view of embryotoxicity findings in animals, and since information on possible adverse effects in pregnant women is limited to uncontrolled clinical data, the drug is not recommended in women who are or may become pregnant unless the potential benefit outweighs the potential risk to mother and fetus.

Usage in Children: No clinical experience is available with the use of Combipres in children.

Precautions: When discontinuing Combipres, reduce the dose gradually over 2 to 4 days to avoid a possible rapid rise in blood pressure and associated subjective symptoms such as nervousness, agitation, and headache. Patients should be instructed not to discontinue therapy without consulting their physician. Rare instances of hypertensive encephalopathy and death have been recorded after cessation of clonidine hydrochloride therapy. A causal relationship has not been established in these cases. It has been demonstrated that an excessive rise in blood pressure, should it occur, can be reversed by resumption of Combipres therapy or by intravenous phentolamine.

Patients who engage in potentially hazardous activities, such as operating machinery or driving, should be advised of the sedative effect of the clonidine hydrochloride component. This drug may enhance the CNS-depressive effects of alcohol, barbiturates and other sedatives. Like any other antihypertensive agent, Combipres should be used with caution in patients with severe coronary insufficiency, recent myocardial infarction, cerebrovascular disease or chronic renal failure.

As an integral part of their overall long-term care, patients treated with Combipres should receive periodic eye examinations. While, except for some dryness of the eyes, no drug-related abnormal ophthalmological findings have been recorded with Catapres, in several studies the drug produced a dose-dependent increase in the incidence and severity of spontaneously occurring retinal degeneration in albino rats treated for 6 months or longer.

Patients predisposed toward or affected by diabetes should be tested periodically while receiving Combipres, because of the hyperglycemic effect of chlorthalidone.

Because of the possibility of progression of renal failure, periodic determination of the BUN is indicated. If, in the physician's opinion, a rising BUN is significant, the drug should be stopped.

The chlorthalidone component of Combipres may lead to sodium and/or potassium depletion. Muscular weakness, muscle cramps, anorexia, nausea, vomiting, constipation, lethargy or mental confusion may occur. Severe dietary salt restriction is not recommended in patients receiving Combipres.

Periodic determinations of the serum potassium level will aid the physician in the detection of hypokalemia. Extra care should be given to detection of hypokalemia in patients receiving adrenal corticosteroids, ACTH or digitalis. Hypochloremic alkalosis often precedes other evidence of severe potassium deficiency. Frequently, therefore, more sensitive indicators than the potassium serum level are the serum bicarbonate and chloride concentrations. Also indicative of potassium depletion can be electrocardiographic alterations such as changes in conduction time, reduction in amplitude of the T wave; ST segment depression; prominent U wave. These abnormalities may appear with potassium depletion before the serum level of potassium decreases. To lessen the possibility of potassium deficiency, the diet, in addition to meat and vegetables, should include potassium-rich foods such as citrus fruits and bananas. If significant potassium depletion should occur during therapy, oral potassium supplements in the form of potassium chloride (3 to 4.5 gm/day), fruit juice and bananas should be given.

Adverse Reactions: The most common reactions are dry mouth, drowsiness and sedation. Constipation, dizziness, headache, and fatigue have been reported. Generally these effects tend to diminish with continued therapy.

Clonidine hydrochloride: Anorexia, malaise, nausea, vomiting, parotid pain, mild transient abnormalities in liver function tests; one case of possible drug-induced hepatitis without icterus and hyperbilirubinemia in a patient receiving clonidine hydrochloride, chlorthalidone and papaverine hydrochloride. Weight gain, transient elevation of blood glucose, or serum creatine phosphokinase; congestive heart failure, Raynaud's phenomenon; vivid dreams or nightmares, insomnia, other behavioral changes, nervousness, restlessness, anxiety and mental depression. Also rash, angioneurotic edema, hives, urticaria, thinning of the hair, pruritus not associated with a rash; impotence, urinary retention; increased sensitivity to alcohol, dryness, itching or burning of the eyes, dryness of the nasal mucosa, pallor, gynecomastia, weakly positive Coombs' test, asymptomatic electrocardiographic abnormalities manifested as Wenckebach period or ventricular trigeminy.

Chlorthalidone: Symptoms such as nausea, gastric irritation, anorexia, constipation and cramping, weakness, dizziness, transient myopia and restlessness are occasionally observed. Headache and impotence or dysuria may occur rarely. Orthostatic hypotension has been reported and may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics. Skin rashes, urticaria and purpura have been reported in a few instances.

A decreased glucose tolerance evidenced by hyperglycemia and glycosuria may develop inconsistently. This condition, usually reversible on discontinuation of therapy, responds to control with antidiabetic treatment. Diabetics and those predisposed should be checked regularly.

As with other diuretic agents hypokalemia may occur (see Precautions). Hyperuricemia may be observed on occasion and acute attacks of gout have been precipitated. In cases where prolonged and significant elevation of blood uric acid concentration is considered potentially deleterious, concomitant use of a uricosuric agent is effective in reversing hyperuricemia without loss of diuretic and/or antihypertensive activity.

Idiosyncratic drug reactions such as aplastic anemia, thrombocytopenia, leukopenia, agranulocytosis, and necrotizing angiitis have occurred, but are rare.

The remote possibility of pancreatitis should be considered when epigastric pain or unexplained gastrointestinal symptoms develop after prolonged administration.

Other adverse reactions which have been reported with this general class of compounds include: jaundice, xanthopsia, paresthesia and photosensitization.

Overdosage: *Catapres (clonidine hydrochloride):* Profound hypotension, weakness, somnolence, diminished or absent reflexes and vomiting followed the accidental ingestion of Catapres by several children from 19 months to 5 years of age. Gastric lavage and administration of an analeptic and vasopressor led to complete recovery within 24 hours. Tolazoline in intravenous doses of 10 mg at 30-minute intervals abolishes all effects of Catapres overdosage.

Chlorthalidone: Symptoms of overdosage include nausea, weakness, dizziness, and disturbances of electrolyte balance. There is no specific antidote, but gastric lavage is recommended, followed by supportive treatment. Where necessary, this may include intravenous dextrose and saline with potassium administered with caution.

How Supplied: Combipres® 0.1 (Each tablet contains clonidine hydrochloride 0.1 mg + chlorthalidone 15 mg). It is available as pink, oval, single-scored compressed tablets in bottles of 100.

Combipres® 0.2 (Each tablet contains clonidine hydrochloride 0.2 mg + chlorthalidone 15 mg). It is available as blue, oval, single-scored compressed tablets in bottles of 100.

For complete details, please see full prescribing information.

VENTRICULAR FIBRILLATION THRESHOLD DURING PROPRANOLOL WITHDRAWAL

Zvi Ziskind, MD; Aram Smolinsky, MD: Daniel A. Goor, MD; Dept. of Cardiac Surgery, Sheba Medical Centre, Sackler School of Medicine, University of Tel-Aviv.

Abrupt propranolol withdrawal is known to cause increased ventricular excitability in general patients and those post aorto-coronary bypass. The electrophysiological aspect of this phenomenon was investigated in the present study by measuring the ventricular fibrillation threshold (VFT) in dogs subjected to such treatment. Eight dogs received propranolol, 3 mg/kg daily, p.o., for two weeks, after which the drug was abruptly discontinued. 48 hours later the VFT was measured as the current required to induce ventricular fibrillation in two stimulation methods: 1) single constant current pulse, synchronized to occur during the vulnerable period; and 2) a train of pulses at 60 Hz, synchronized to occur 50-450 msec after the QRS. Ten dogs served as control. While on propranolol, the dogs' heart rate (HR) slowed from 115 (±5) to 77 (±4). 48 hours after drug withdrawal the HR rose to 159 (±11). Using single pulse stimulation, VFT decreased from 31 ± 2.16 mamp - control group, to 11.2 ± 1.8 mamp - propranolol withdrawal group. Using train of pulses stimulation, VFT decreased from 5.28 ± 0.95 - control group to 1.54 ± 0.32 - test group. This threefold drop in VFT compared to control values is highly significant ($p<0.001$, t-test) and points to an additional hazard of abrupt propranolol discontinuation.

PREVENTION OF POSTOPERATIVE SUPRAVENTRICULAR TACHYARRHYTHMIA IN CORONARY BYPASS PATIENTS, WITH LOW-DOSE PROPRANOLOL

Rephael Mohr, MD; Aram Smolinsky, MD; Daniel A. Goor, MD; Dept. of Cardiac Surgery, Chaim Sheba Medical Centre, University of Tel-Aviv, Israel.

The increased tendency of patients (pts) to develop supraventricular tachyarrhythmia (SVT) after aorto-coronary bypass (ACBP) is attributed to supersensitivity after Propranolol withdrawal. This study examined the effect of early readministration of Propranolol via nasogastric-tube, on the incidence of postoperative SVT. Eighty-five consecutive pts receiving long-term Propranolol therapy were randomized after ACBP to either receive mini-dose Propranolol (Group I) or serve as controls (Group II). They were compared with 18 pts (Group III) who did not receive beta-blockers prior to surgery, but were given Propranolol postoperatively. Poor risk pts (left ventricular aneurysms, low ejection fraction, congestive heart failure) were included in the study. All 3 Groups were comparable on all risk factors. Propranolol (5-10 mg orally every 6 hrs) was started through nasogastric-tube 6 hrs after surgery & continued orally in pts of Groups I & III. SVT appeared in 2 of 37 pts in Group I (5%), 19 of 48 pts in Group II (40%) & 5 of 18 pts in Group III (27%). The incidence of SVT was significantly lower in Group I than in Groups II & III ($p<0.001$ Group I vs. Group II, $p<0.01$ Group I vs. Group III). These results show that early reinstitution of low-dose Propranolol following ACBP can prevent SVT in pts receiving beta-blocking agents preoperatively.

SURGERY FOR CONGENITAL HEART DISEASE: FOLLOW-UP STUDIES
2:00-3:30

ECHOCARDIOGRAPHIC AND ANGIOCARDIOGRAPHIC FEATURES BEFORE AND AFTER THE JATENE PROCEDURE(ARTERIAL SWITCH)FOR TRANSPOSITION OF THE GREAT ARTERIES.

Walter J. Duncan,MD,;Peter M.Olley,MD,FACC;Richard D.Rowe, MD,FACC;Robert M.Freedom,MD,FACC;William G.Williams,MD; George A.Trusler,MD. The Hospital for Sick Children, Toronto,Ontario,Canada.

Eight patients with transposition of the great arteries (d-TGA)and associated anomalies have undergone Jatene's procedure with correction of associated anomalies.Six patients survived and were studied pre and post operatively by M-mode(M)and two-dimensional echocardiography(2DE) as well as by cardiac catheterization(C)and angiography (A).Pre-operative M studies showed panchamber enlargement and diagnosed d-TGA in all.Left ventricular outflow tract (LVOT)narrowing was present in 2 patients-one of these also had systolic anterior mitral motion(SAM).2DE confirmed the additional features of isolated ventricular septal defect(VSD)in 2 patients;double outlet right ventricle in 2,patent ductus arteriosus in 2 and right atrio-ventricular valve atresia(TA)in 2.Post operatively, M showed normal systemic ventricular function in 5 patients.No patient showed LVOT narrowing or SAM.Right ventricular(RV)size was increased in 4 patients(RV remained small in both patients with TA).2DE showed patent coronary ostia in all and no dysynchronous wall motion was apparent except in the area of the VSD patch.C and A have confirmed good results in all but one patient who had impaired ventricular function pre operatively.One patient has stenosis of the right coronary ostium by A--2 have mild aortic regurgitation.None have significant LVOT gradients and only one has a significant right ventricular outflow tract gradient(47mmHg).In summary,M,2DE,C and A all contribute to assessment of patients before and after the Jatene procedure.

RADIONUCLIDE ASSESSMENT OF LEFT VENTRICULAR FUNCTION IN PATIENTS WITH TRICUSPID ATRESIA

Joyce R. Harder, MD; David L. Gilday, MD; Margaret deSouza, MA; Robert M. Freedom, MD, FACC; Peter M. Olley, MD, FACC; Richard D. Rowe, M.D, The Hospital for Sick Children, Toronto, Canada.

Accurate evaluation of LV function in patients with tricuspid atresia (TAT) has become necessary since the introduction of the Fontan and similar operations. We have used multiple gated blood pool analysis (MUGA) to assess LV ejection fraction (EF) at rest, and during exercise (EX) in 20 patients with TAT. Age ranged from 6.5 to 22 years, median 10 years. Eleven patients were male and 9 female. Resting EF was normal in 13 patients (mean 63.6 ± 5.3%) Group 1, and abnormal in 7 (mean 47.7 ± 5.6%) Group 2. Eleven patients in Group 1 increased EF during EX (mean 7.4 ± 2.5%), 2 showed a decrease. EX EF in Group 2 fell in 5 patients and increased slightly in 2. No ST segment depression was noted in any patient with an EX EF increase of greater than 5%. Of the 2 patients in Group 1 with a drop in EX EF, only 1 showed ST segment depression. In Group 2 5/7 patients demonstrated ST segment change. Mean age of patients in Group 1 was 13.7 ± 5 years as compared to 14.6 ± 3 years in Group 2. Mean resting 0_2 saturation did not differ significantly between the groups. Prior surgical procedures included multiple shunts in 11 patients, Glenn only in 4, Fontan in 4. Mean resting EF in each surgically treated subgroup did not differ significantly. These results suggest that 1) MUGA is a valuable noninvasive means to evaluate LV function in patients with TAT, 2) response to exercise may be abnormal when resting EF is normal, 3) ST segment change is not consistently present with decreased exercise EF, 4) in our study LV function is relatively well preserved and abnormal function is not related to age, prior surgical procedures, or resting oxygen saturation.

HEMODYNAMIC EVALUATION OF THE FONTAN PROCEDURE AT REST AND WITH EXERCISE

William E. Hellenbrand, MD; Hillel Laks, MD; Charles S. Kleinman, MD; Norman S. Talner, MD, Yale University School of Medicine, New Haven, CT

Hemodynamic assessment was performed in seven patients (pts) one year following a Fontan procedure. The diagnoses included tricuspid atresia (4), pulmonary atresia (1), mitral atresia (1) and a criss-cross heart (1). Mean age at operation was 15 (8-21 years). At surgery, a 25 mm porcine conduit was interposed between the right atrium (RA) and the right ventricle (RV) in three pts and between the RA and pulmonary artery (PA) in 4. The tricuspid valve was closed in 2 pts and the RA partitioned in one. There was an SVC-RPA anastomosis present in 3 pts. Five of the seven pts were asymptomatic with two in a chronic low output state. Hemodynamic evaluation was performed at rest and during supine exercise. At rest, mean cardiac index (CI) was 2.0 L/min/M^2 with RA-PA conduits and 2.7 L/min/M^2 with RA-RV conduits. Right atrial mean pressure averaged 20 mmHg in RA-PA conduits and 10 mmHg in RA-RV conduits. An "a" wave gradient was present across the porcine valve in the RA-RV conduits ranging from 2 to 10 mmHg with no pressure difference in the RA-PA conduits. Left ventricular ejection fraction was low normal with a mean of 0.55. During exercise, CI increased from 2.7 to 4.1 L/min/M^2. The entire augmentation in systemic flow was dependent on the change in heart rate. Mean right atrial pressure increased from 11 to 19 mmHg. When changes in cardiac output were related to oxygen consumption during exercise all pts were abnormal with a mean exercise factor of 4 (normal > 6). Continuous antegrade flow into the pulmonary arteries was present during systole and diastole in 6 pts. Despite clinical improvement following the Fontan operation abnormal hemodynamics are present at rest and become more significant with exercise.

REST AND EXERCISE HEMODYNAMICS AFTER FONTAN PROCEDURE.

Giora Ben Shachar, MD, Bradley P. Fuhrman, MD, Yang Wang, MD, Russell V. Lucas, MD, James E. Lock, MD; University of Minnesota, Minneapolis, Minnesota.

Sixteen patients, aged 5-26, underwent a Fontan procedure with no operative deaths. Two late deaths were sudden and unexpected. Marked clinical improvement occurred in most survivors; 11 of 14 were NYHA class I or II. Eleven of the 14 agreed to postop catheterization. Four had developed right-to-left shunts through an oversewn atrioventricular valve ring, invalidating CI measurement. Hemodynamic data on the remaining 7 patients, including 4 at both rest and exercise, were compared to published results in normals of similar age. None of the exercised patients had a previous Glenn anastomosis; all were NYHA class I.

Fontan:	N	C.G. mmHg	Mean RA Pressure mmHg	C.I. L/min/M^2	Stroke Index ml/min/M^2	PA O_2 Saturation (%)
Rest	7	2±1	14±3*	2.3±0.3*	29±6*	64±10*
Pre-exercise	4	2±1	14±2*	2.4±0.3*	30±8*	68±9
Exercise	4	8±5	26±4*	4.8±1.2*	33±14*	32±7*
Normal rest	23	-	4±2	4.4±0.7	53±10	76±4
" exercise	23	-	3±3	8.0±1.3	57±11	50±10

At rest, the CI (Fick) was low due to a small stroke index, despite normal PA pressures and a minimal conduit gradient (CG). Exercise resulted in marked PA desaturation, small rise in CI, and the appearance of a variable (5-13) but significant CG.

Despite substantial clinical improvement after Fontan procedure, these data demonstrate a decreased CI both at rest and at exercise. Further, marked RA hypertension and functional conduit obstruction occur with exercise, even in patients with favorable clinical results. The long-term implications of these results are unknown. (Data are mean ± S.D. *$p<0.05$ when compared with normal).

LATE RESULTS OF OPERATION FOR DISCRETE SUBAORTIC STENOSIS

Glenn R. Barnhart, M.D.; Michael Jones, M.D.; Andrew G. Morrow, M.D., National Heart Institute, Bethesda, Md.

Between 1956 and 1979 we performed complete resection of the fibrous ring in 53 patients with discrete subaortic stenosis. Six patients had associated anomalies: PDA, VSD, RV outflow obstruction, and/or Ao to RV fistula. Five patients suffered perioperative deaths; 4 were during our very early experience. Excluding 12 foreign patients, late follow-up evaluations including cardiac catheterizations were performed at our institution for all 36 survivors 1 to 24 years (mean 12.2 years) postoperatively. Gradients preoperatively averaged 98 mm Hg (35-190); gradients at 2 to 168 months (mean 18 months) postop averaged 38 mm Hg (0-200). Eight patients had residual gradients over 50 mm Hg, of whom 6 had the tunnel form of LV outflow obstruction. There were 6 late cardiac deaths. Of the long-term survivors 23 of 30 are asymptomatic. Six patients have required reoperation, and 3 patients have developed bacterial endocarditis. Aortic regurgitation was present in 22 patients preop; 5 additional patients have it late postop. Cardiothoracic ratios averaged 0.53 preop and 0.44 late postop. ECG criteria for LVH were present in 26 patients preop and in 10 late postop. Average echocardiographic LV systolic and diastolic dimensions were normal late postop, 30 and 49 mm, respectively. Actuarial survival is 94% at 5 years (n=28), 87% at 10 years (n=22), and 81% at 20 years (n=7). Survival without adverse cardiac abnormalities (reoperation, bacterial endocarditis, residual gradient >50 mm Hg, cardiothoracic ratio >than 0.60, or definite LVH by ECG criteria) is similar at 5 years (54%) and at 10 years (55%). We conclude that resection relieves symptoms and obstruction and gives satisfactory late results for most patients with discrete subaortic stenosis, but residual cardiac abnormalities require continuing long-term follow-up.

TETRALOGY OF FALLOT: 11 YEAR EXPERIENCE IN NEW ENGLAND

Lucy P. Buckley, MD and Donald C. Fyler, MD, FACC, New England Regional Infant Cardiac Program, Children's Hospital Medical Center, Boston, MA

Over the past 11 years, 407 of 4,505(9%) infants born in New England with critical congenital heart disease had tetralogy of Fallot(TF) as their major cardiac malformation. Despite a 25% drop in birthrate, the number of new patients over the years did not vary and case discovery increased from .18 to .25 per 1000 live births. Overall, 102 of 407(25%) infants died before their first birthday and the loss was twice as great among the 87 infants admitted within the first 48 hours of life. As expected, mortality was greater among those with associated cardiac lesions: coronary abnormalities(20), absent pulmonary valve(13), absent pulmonary artery(8), arch anomalies (10) aortic and mitral problems(9), congenital complete heart block(3), total anomalous pulmonary venous return(2), cor triatriatum (1), aorticopulmonary window(1), juxtaposition atrial appendages(1) and Ebstein's anomaly(1). When the 118 of 407 (29%) "high risk" infants with low birthweight (<2.5kg) and/or severe associated anomalies were excluded, first year medical mortality was halved but surgical mortality was unchanged.

Among the 313 infants with TF, 187 (60%) were managed surgically: operative mortality was 17%(18 of 108) for palliative shunts and 26%(19 of 74) for primary repair. Mortality was significantly higher among the 94 infants with pulmonary atresia with ventricular septal defect: shunt mortality was 30%(16 of 54) and 2 of 3 died at attempted repair. Of the 45 infants operated in 1968-69, 42 were shunted and 14(31%) died, whereas of the 43 infants operated in 1977-78, 25 were repaired and 4(9%) died.Comparison of surgical experience over time suggests that primary repair of TF syndrome in the first year of life is superior to palliative shunting and later repair.

INTRACARDIAC ELECTROPHYSIOLOGIC STUDIES
2:00-3:30

RESULTS OF PROGRAMMED STIMULATION IN 80 PATIENTS HAVING A HISTORY BUT NO ELECTROCARDIOGRAPHIC DOCUMENTATION OF TACHYCARDIA.

Hein J.J. Wellens, MD, FACC; Frits W.H.M. Bär, MD; Eddy J.D.M. Vanagt, MD; Pedro Brugada, MD; Willem R.M. Dassen, PhD, Dept. of Cardiology, University of Limburg, Annadal Hospital, Maastricht, The Netherlands.

Identification of site of origin and mechanism of tachycardia(T) is important for proper selection of therapy. Therefore 80 consecutive patients(P) having a history of paroxysmal T but no electrocardiographic documentation were studied by programmed electrical stimulation(PES) of the heart. If no T could be initiated during PES, Atropine was given and PES repeated.
Results: Sustained T could be initiated by PES in 53 P (66%). Site or origin of T was: Atrial 8, AV-nodal: 19 (in 7 P T could only be initiated after Atropine), Ventricular: 6. In 5 P a concealed accessory pathway was used during T. In all 15 P showing a WPW electrocardiogram a circusmovement T with atrio-ventricular conduction over the AV-node and ventriculo-atrial conduction over the accessory pathway could be initiated by PES.
Conclusions: 1) In all 15 P having a WPW electrocardiogram and a history of T a circusmovement T could be initiated during PES. 2) In the remaining 65 P sustained T could be initiated in 38 P (= 58%). 3) T originated in different sites in the heart, AV-nodal T being the most common type.

THE ELECTROPHYSIOLOGIC ASSESSMENT OF PATIENTS WITH SYNCOPE

Robert O. Brandenburg, Jr., MD; David R. Holmes, Jr., MD, FACC; Geoffrey O. Hartzler, MD, FACC, Mayo Clinic, Mayo Foundation, Rochester, MN.

From 1977 to 1980, 92 patients (pts) with syncope of unknown etiology underwent invasive electrophysiologic (EP) studies to determine the mechanism of their syncope. Prestudy investigations including 12-lead electrocardiography (92 pts), 24 hour Holter monitoring (75 pts), exercise testing (24 pts), and neurologic assessment including electroencephalograms (63 pts) had failed to identify an etiology in any patient. There were 55 males and 37 females (mean age 58 years) with a mean of 9.1 episodes of syncope per patient which had occurred over a mean of 20.8 months prior to the EP study.

EP testing documented a probable cause for syncope in 59 of the 92 pts (64%). The most common abnormality was identifiable His-Purkinje conduction system disease which was found in 14 pts. The remaining pts were found to have carotid sinus hypersensitivity (11 pts), hypervagotonia (10 pts), ventricular dysrhythmias (10 pts), supraventricular tachycardia (9 pts), and intrinsic sinus node dysfunction (5 pts). Based on the EP testing, therapy directed at the specific mechanism of syncope was initiated. Follow-up data was available for 54 of the 59 pts (91%). During a mean follow-up of 14.2 months (range 4 to 38 months), 48 pts (89%) remained free of syncope on treatment. Two additional pts (4%) were improved on treatment but still had symptoms. The remaining 4 pts remained unchanged and in one of these an additional mechanism for syncope was documented.

We conclude that EP testing plays a valuable role in the evaluation of pts with syncope of unknown etiology. It may identify the potential mechanism for syncope and facilitates selection of specific treatment modalities.

UNEXPLAINED SYNCOPE: RESULTS OF THERAPY BASED ON ELECTROPHYSIOLOGIC STUDIES.

JOHN P. DIMARCO, MD, HASAN GARAN, MD, J. WARREN HARTHORNE, MD, FACC, JEREMY N. RUSKIN, MD, FACC. MASSACHUSETTS GENERAL HOSPITAL, BOSTON, MASS.

Twenty-one patients with recurrent syncope that remained unexplained after thorough medical and neurologic evaluations underwent intracardiac electrophysiologic study (EPS) with atrial and ventricular programmed stimulation (PS). Patients with bifascicular block and 1° AV block on baseline ECG were excluded. Syncope had been present for from 3-96 months and each patient had had 3 or more prior episodes. Results of EPS were considered diagnostic in 6 patients with rapid ventricular tachycardia [271±11 (mean ±S.D.) beats per minute] induced by PS, in 3 patients with intra-His conduction delays, in 1 patient with induced atrial flutter and a rapid ventricular rate, and in 1 patient with sinus node dysfunction and induced atrial flutter. In 3 other patients, EPS revealed a persistent prolongation of AV nodal refractoriness that was reversible with atropine suggesting increased vagal tone as a possible mediator for syncope. Based on these findings at EPS, therapy was instituted with either antiarrhythmic drugs (8 patients), ventricular pacing (5 patients), or both (1 patient) with complete relief from recurrent syncope in 12 patients, marked improvement in 1 patient, and no change in 1 patient over 17.8± 5 months of follow-up. Syncope persists and remains unexplained in 3 of the 7 patients in whom EPS did not suggest an etiology. These observations indicate that EPS with PS should be utilized in the diagnostic evalaution of selected patients with recurrent unexplained syncope, since such testing may reveal arrhythmias or conduction system disease which are not demonstrable by noninvasive techniques. Specific prophylactic therapy directed against abnormalities detected by electrophysiologic testing is highly effective in preventing the recurrence of syncope.

NODAL FUNCTION IN 30 PATIENTS WITH ATRIOVENTRICULAR NODAL 1/1 CONDUCTION ABOVE 200/MN.

Robert Frank, M.D., Guy Fontaine, M.D., Hoan Phan-Thuc, M.D., Patrick Blanc, M.D.
Hôpital de la Salpêtrière, Paris, France.

In normal adults, it has been considered that 1:1 conduction of atrial impulses to the ventricles above a rate of 200/mn is indicative of an atrioventricular (AV) nodal bypass tract. In order to examine this contention, we reviewed the records of 600 consecutive adult patients who had electrophysiologic study and found 30 with 1:1 AV nodal conduction at atrial rates above 200/mn.

Under basal conditions, the AH time was abnormally short (50ms or less) in 22 cases. The nodal effective refractory period was normal for the cycle length in 9, and could not be assessed in 21 because it was atrial limited. The nodal functionnal refractory period was normal in all. H1H2 vs A1A2 curve by the extrastimulus techniques was normal in 15, 5 had a plateau, 4 had a dual curve and 6 were undetermined. AH vs RR curve with atrial pacing by step of increasing rates had a constant slope in 15, 8 had 2 or 3 slopes and 7 had a plateau followed by a slope. In none of these 30 patients could AV nodal reentrant supraventricular tachycardia be induced.

Vagal stimulation was provoqued in each patient by injection of ATP (10 or 20mg IV bolus). In each patient first and second degree AV block occured within the AV node.

Therefore 1) since AV conduction prolonged or ceased in all patients with vagal stimulation, we concluded that an extranodal bypass tract was not responsible for an enhanced AV conduction, 2) enhanced AV conduction is not a prediction of AV reentrant supraventricular tachycardia, 3) an "enhanced" AV conduction may be due to a great variety of nodal responses.

IITIATION OF ATRIO-VENTRICULAR NODAL RE-ENTRANT TACHY-
ARDIA IN PATIENTS WITH DISCONTINUOUS ANTEGRADE CONDUC-
ION CURVES. IMPORTANCE OF A DISCONTINUOUS RETROGRADE
ONDUCTION CURVE.

edro Brugada, MD; Eddy J.D.M. Vanagt, MD; Frits W.H.M.
ir, MD; Willem R.M. Dassen, PhD; Hein J.J. Wellens, MD,
ACC, Dept. of Cardiology, University of Limburg, Annadal
ospital, Maastricht, The Netherlands.

o study factors playing a role in initiation of sustained
rio-ventricular nodal tachycardia(S AVN T), antegrade
A) and retrograde(R) conduction curves(CC) were determined
sing the extrastimulus technique at 2 different basic cycle
engths(BCL) in 25 patients(pts) without accessory pathway.
s were grouped according to: Discontinuous(D) ACC and
ontinuous RCC at both BCL (GROUP 1, 14 pts), or DACC at
oth BCL and DRCC at 1 or 2 BCL (GROUP 2, 11 pts). Mode of
nitiation of S AVN T - 1 atrial premature beat(APB),
ultiple(M) APB, or atrial pacing at increasing rates(IR)-
as studied in both groups. If S AVN T was not initiated,
ng atropine(ATR) was given intravenously and the study
epeated.

ESULTS: Number of pts and mode of initiation of S AVN T

ROUP	1 APB	MAPB	IR	AFTER ATR
1	13/14	-	-	1/1
2	1/11	1/10	0/9	6/9

here was a significant difference in: a) initiation of S
VN T by a single APB, b) need of ATR administration to
nitiate S AVN T, c) relation between the longest A-H
nterval of the slow A-V nodal pathway and the value of
he R refractory period of the fast pathway, and d) elec-
rocardiographic documentation of the arrhythmia (12 in
roup 1, 1 in group 2).
ONCLUSIONS: 1) Initiation of S AVN T is unlikely in the pre-
ence of a DRCC unless ATR is used. 2) Pts with documented
have a shorter R refractory period of their fast A-V nodal
athway.

NALYSIS OF ANTEGRADE AND RETROGRADE FAST PATHWAY
ROPERTIES IN DUAL PATHWAY PATIENTS

obert Bauernfeind, MD, FACC; Steven Swiryn, MD, FACC;
hristopher Wyndham, MD, FACC; Boris Strasberg, MD; Edwin
alileo, MD; Kenneth Rosen, MD, FACC, University of
llinois, Chicago, Illinois.

n a previous study, we found an unexpectedly high preva-
ence (17%) of short PR among patients (pts) with dual
athway (DP) AV nodal reentrant tachycardia (PSVT). One
equirement for PSVT is that the retrograde (R) fast path-
ay (FP) have the ability to sustain sequential conduction
SC). In the present study, we examine SC of antegrade
A) and R FP as functions of AH interval (FP conduction
ime during sinus rhythm). In 160 pts with DP (with and
ithout PSVT), AH ranged from 46 to 234 msec (mean $\pm$ SD,
1 $\pm$ 30). Incremental atrial pacing was used to assess
FP SC. Slowest paced cycle lengths (CL) at which AFP SC
ailed (resulting in slow pathway conduction) ranged from
73 to 857 msec (438 $\pm$ 112). Regression analysis of these
L vs AH revealed $r = 0.40$ ($p < 0.01$). Incremental ventric-
lar pacing was used to assess RFP SC in 123 pts. Intact
SC was present in 91 pts and absent in 32 pts, being
resent in 15/15 pts with AH $<$ 60, 70/98 pts with AH 60-
30, and 6/10 pts with AH $>$ 130 ($p < 0.05$). Intact R SC was
resent at CL $\leq$ 400 in 11/15 pts with AH $<$ 60, 44/98 pts
ith AH 60-130, and 2/10 pts with AH $>$ 130 ($p < 0.05$). In
onclusion, there is a relationship between AH and ability
f AFP for SC (pts with shorter AH having better AFP SC).
here is a similar relationship between AH and ability of
FP for SC, implying that RFP is same pathway as AFP. In
population of pts with DP, pts with shorter AH (and PR)
re predisposed to PSVT, by virtue of better SC of RFP.

ADVANCES IN PACING
2:00-3:30

EVALUATION OF PACING FUNCTION BY REAL TIME TWO-DIMENSIONAL ECHOCARDIOGRAPHY

Bapineedu Gondi, MD, Navin C. Nanda, MD, FACC, University of Rochester Medical Center, Rochester, NY

Our experience in 101 patients (pts) with pacing catheters has demonstrated the usefulness of two-dimensional echocardiography (2D echo) in the evaluation of pacing function (ATL 90° sector scanner). 2D echo provided direct evidence for myocardial wall perforation by temporary pacing catheters (PCs) in 5 pts. In 3 pts with loss of sensing and/or increased pacing threshold the PCs were seen penetrating RV apex with the tip lying 2 mm to 1 cm outside the heart border. In 1 pt the PC was repositioned under 2D echo control in another area of RV apex with decrease in pacing threshold from 15mA to 0.5mA. Pericardial effusion was observed in 2 pts, in one of whom it was localized to the site of perforation; neither pt showed cardiac tamponade. The 4th pt showed perforation of the atrioventricular septum with the PC in LV and the 5th pt showed partial penetration of ventricular septum. Both showed right bundle branch block pattern and the withdrawal intracardiac ECG was typical of perforation in the 5th pt. In 4 of 5 pts the identification and abnormal location of the PC was confirmed during PC withdrawal when movements of the PC could be seen to correspond with manual manipulations. Perforation was verified at autopsy in 2 pts, including 1 pt in whom PC was not withdrawn. In 1 of 4 pts with epicardial PC the tip was seen extending into the ventricular chamber (reverse perforation). PC displacement into a hepatic vein was diagnosed in 1 pt in whom chest X-ray suggested myocardial wall perforation. Lead breakage near the pulse generator was detected in 1 pt with intermittent capture. We also found 2D echo useful to accurately position catheters in the RV apex (2 pts) and below the tricuspid valve in contact with ventricular septum for His bundle recordings (2 pts).

P SYNCHRONOUS PACING: A NEW ORTHOGONAL APPROACH TO P-WAVE SENSING

BN Goldreyer, MD, FACC; AL Olive; J Leslie; DS Cannom, MD, FACC; MG Wyman, MD, FACC; San Pedro Peninsula Hospital, San Pedro, California.

P synchronous pacing has long been identified as advantageous for patients with AV conduction defects and intact sinus node function. Prior endocavitary systems have been infrequently employed, because of unreliable P wave sensing from standard ring electrodes in the atrium or the requirement for a second atrial sensing lead. A single endocardial lead employing a unipolar ventricular stimulating electrode and an orthogonal P wave sensing design was developed and tested in 22 patients undergoing electrophysiologic study or pacemaker implantation.

Thirteen cm from the stimulating tip of a standard permanent pacing lead, 3 or 4 electrodes with a surface area of 1 mm^2, equidistant from the tip were placed circumferentially about the catheter. With the catheter tip normally placed in the RV apex, atrial sensing electrodes were positioned in the mid-high lateral RA, adjacent to, but not affixed to the RA wall. Bipolar orthogonal leads X and Y were obtained. In 22 patients, during sinus rhythm, atrial electrogram voltages in the X axis of 2.47 $\pm$ 1.6 mv and 2.32 $\pm$ 1.6 mv in the Y axis were recorded. QRS voltages of 0.078 mv and 0.073 mv respectively allowed dramatic ability to discriminate P from QRS complexes (P/QRS = 32/1). There was no change in QRS voltages recorded during spontaneous PVC's, bipolar or unipolar ventricular pacing.

A single catheter designed for P synchronous pacing employing circumferentially placed atrial sensing electrodes has demonstrated unique atrial sensing voltages with excellent QRS signal rejection.

GATED RADIONUCLIDE ANGIOGRAPHY DURING UPRIGHT EXERCISE IN PATIENTS WITH PROGRAMMABLE PACEMAKERS

Richard Steingart, MD; Corine Yee, MD; John Wexler, MD, PhD; Larry Weinstein, MD; Robert Bontemps, BS; Seymour Furman, MD, FACC, Montefiore Hospital and Medical Center, Bronx, NY

Present generation programmable pacemakers allow for non-invasive selection of a wide range of pacing rates. However, the choice of pacing rate is often arbitrary, or dictated by symptomatic complaints that may be non-specific. Gated radionuclide angiography (GRA) is an accurate, reproducible method for quantitating EF, relative cardiac output (CO), stroke volume (SV), end diastolic volume (EDV) and end systolic volume (ESV) at rest and during exercise and therefore may provide a means to determine optimal, individualized pacing rates. Pts. with fixed bradycardias undergoing programmable ventricular pacemaker implantation were selected for study. After in vivo red cell labeling with 20 mCi of 99mTc, upright GRA was performed at rest and during low level bicycle exercise (75 kilopond-meters) at the baseline pacing rate (69±4 beats/min). The rest-exercise protocol was then repeated at pacing rates 20 beats/min above and below baseline. The entire procedure required less than 1 hour for completion and was performed as early as 24 hours after pacemaker implantation. In a representative study of a pt. with coronary artery disease, at rest in the upright posture, relative CO was not influenced by changing the pacing rate as EDV and SV varied inversely with heart rate. However, both EDV and ESV rose during exercise at all heart rates with a resultant increase in CO of 20% at a heart rate of 85 beats/min, and a 48% decrease in CO at a heart rate of 45 beats/min when compared with values during exercise at 65 beats/min.

We conclude that rest-exercise GRA is a valuable aid in determining optimal pacing rates in selected patients undergoing programmable pacemaker implantation.

AUTODECREMENTAL ATRIAL PACING FOR TACHYCARDIA TERMINATION-A CLINICAL EVALUATION

John Camm,MB;Anthony Nathan,MB;Kevin Hellestrand,MB; David Ward,MB;Roworth Spurrell,MD,FACC. St.Bartholomew's Hospital,London,England.

Autodecremental atrial pacing was assessed during electrophysiological study in 20 consecutive patients with recurrent supraventricular tachycardia(T).8 had intranodal T and 12 had atrioventricular T.T cycle length ranged from 250 to 420(mean 351)msec.
The system consists of sensing and pacing circuits controlled by a small computer.T is defined as 8 successive P-P intervals less than a preset value.The first pacing cycle interval is the T cycle length minus a decrement value(D).Each subsequent pacing cycle is further reduced by the same value of D.The maximum pacing rate is 100 beats/min faster than T,with an absolute limit of 275 beats/min.Several durations of pacing (P) were assessed. If T continues,pacing resumes after 8 cycles with a different value of either P or D or both,21 different combinations were evaluated(with P:500,1000,5000msec;and D: 2,4,8,16,24,34,50msec).The complete cycle was repeated 3 times in each patient.
With P:500,only 2/20 T were terminated,but with P:1000, 16/20 were terminated.All T were terminated with P:5000. The only combination successful in all patients was P:5000 and D:16.No unwanted arrhythmias were induced,but in the same group rapid atrial pacing induced atrial flutter in 4 patients,being successful in the remainder.
Scans of 1 or 2 atrial or ventricular premature stimuli were successful in 18/20.The system tends to avoid stimulation in the vulnerable period,but allows stimulation in different phases of the T cycle,increasing the likelihood of safe termination.This pacemaker is capable of development into an inplantable form.

THE USE OF STIMULUS-T INTERVAL TO DETERMINE CARDIAC PACING RATE

Anthony F. Rickards, MRCP,; John Norman, The National Heart Hospital, London, U.K.

The relationship between QT interval and heart rate has been studied in a group of patients undergoing physiological exercise (N=25), atrial pacing without exercise (N=15) and in a group with complete heart block exercising at a fixed ventricular rate controlled by cardiac pacing (N=9). Total QT interval decrease for a predicted increase in heart rate of 100 bpm due to physiological exercise was 187ms, whereas for a similar heart rate increase induced by atrial pacing, the QT decrease was only 66ms. The dichotomy is explained when observations on patients exercising at a fixed ventricular rate show a QT interval decrease of 95 ms for a predicted 100 bpm increase in the independent atrial rate. Thus QT interval is not only a function of intrinsic heart rate, but also of the levels of circulating catecholamines which independently affect repolarisation time.
A cardiac pacemaker using a unipolar ventricular lead has been constructed which senses the interval between the delivered stimulus and the evoked ventricular T wave and sets the subsequent escape interval and thus the overall pacing rate. Physiological control of cardiac pacing rate is therefore possible, independent of atrial activity, using a unipolar ventricular lead.

NON-INVASIVE EVALUATION OF CEREBRAL BLOOD FLOW DURING VENTRICULAR AND A-V SEQUENTIAL PACING

Murray Miller, M.D., Stewart Fox, M.D., Russell Jenkins, M.D., Jon Schwartz, M.D., F. Geoffrey Toonder, M.D., Quakertown Hospital, Quakertown, PA

Over the last 20 years, transvenous ventricular pulse generators (VVI) have become the accepted method for permanent pacing because most patients requiring pacemakers were improved by the VVI. However, some patients do not tolerate the loss of atrial kick which accompanies ventricular pacemaker insertion, and subsequently develop decreased cardiac output and decreased cerebral blood flow. They manifest the cerebral symptoms of lightheadedness, vertigo, and syncope, now recognized as "pacemaker syndrome". Until now, the only way to prevent this syndrome was to recognize the susceptible patient in advance of pacemaker insertion by utilizing a variety of invasive, expensive, and sometimes dangerous testing techniques. We have taken proven, existing equipment and developed an accurate, reproducible, non-invasive testing technique using the OPG-GEE during pacemaker implantation to demonstrate the relative changes in cerebral blood flow during temporary ventricular pacing. These tests enabled us to recognize significant decreases in relative cerebral blood flow in 15 patients. In 14 of these patients, we proceeded to insert an additional atrial electrode and an A-V sequential pulse generator, thus preventing pacemaker syndrome. The one patient not receiving an A-V sequential pacemaker did develop pacemaker syndrome, which resolved upon a subsequent change to an A-V sequential pacemaker system. This newly developed testing technique has broadened our recognition that many more patients would benefit from physiologic pacing to prevent a decrease in cerebral blood flow that frequently accompanies VVI pacing.

METABOLIC ASPECTS OF ACUTE MYOCARDIAL INFARCTION IN THE EXPERIMENTAL MODEL
2:00-3:30

NON-UNIFORM EFFECTS OF SYMPATHETIC NERVE STIMULATION ON VENTRICULAR REFRACTORINESS IN HEALED MYOCARDIAL INFARCTION: COMPARISON TO ACUTE INFARCTION. Marion S. Gaide, PhD; Robert J. Myerburg, MD, FACC; Henry Gelband, MD, FACC; Augustin Castellanos, MD, FACC; Arthur L. Bassett, PhD, University of Miami School of Medicine, Miami, Florida 33101.

Spontaneous arrhythmias occur in cats studied 1-12 months after healing of myocardial infarction (MI) induced by distal coronary ligation. To evaluate the interaction between the sympathetic nervous system and healed MI, we measured local ventricular refractory periods (RP) from the epicardium overlying the MI (I), the border area (B) and a normal area (N), with and without sympathetic nerve stimulation. Atrial and ventricular pacing leads and 3 bipolar test leads (N, B and I) were implanted epicardially in cats (n=6) 2-6 months after induction of MI. The SA node was crushed and right atrium and ventricle were paced 20-30 beats per minute faster than intrinsic rate. RP measurements were made after vagotomy and prior to, during and after bilateral stimulation of ansa subclavia (all proximal connections to the stellates were severed). Sympathetic nerve stimulation induced RP shortening which was greatest in N (-18 ± 2 msec), slightly less in B (-15 ± 3 msec) and least in I (-9 ± 1 msec). In contrast, sympathetic stimulation of similar zones in cats (n=6) before and 60 minutes after induction of an acute MI shortened RP uniformly in N, B and I. We conclude that experimental healed MI alters the effect of epicardial sympathetic nerves on RP, resulting in non-uniform changes in ventricular RP during stimulation. Imbalance of sympathetic outflow, or of ventricular muscle responsiveness to stimulation, may contribute to ventricular arrhythmias in hearts with healed MI.

METABOLIC CHARACTERIZATION OF REVERSIBLE VERSUS IRREVERSIBLE ISCHEMIC DAMAGE
Shukri Khuri, MD; Stephanie Karaffa, B.Sc.; Robert Kloner, MD, Ph.D.; Edward Folland, MD, FACC; Alfred Parisi, MD, FACC; Paul Moynihan, B.Sc. and Ernest M. Barsamian, MD, Harvard Medical School, Boston, Massachusetts

This study was conducted to identify metabolic criteria which would enable the intraoperative differentiation between normal, ischemic (reversible) and infarcted (irreversible) myocardial segments. In 12 open chest dogs, 8 mass spectrometer probes for the determination of intramyocardial oxygen ($Pm0_2$) and carbon dioxide ($PmC0_2$) tensions were placed in infarcted segments (In) of the left ventricular wall (created two years previously by high ligation of the anterior descending coronary artery and documented by angiography and post mortem histology), 8 in normal segments (N), and 8 in ischemic segments (Is) supplied by a critically stenotic circumflex coronary artery. Baseline gas tensions (mean±SEM) and their response to atrial pacing (30% increase in heart rate) were:

	$PmCO_2$ (mmHg)			$Pm0_2$ (mmHg)		
	N	Is	In	N	Is	In
Before pacing	45±5	62±4]*	44±4	16±3	8±2]*	18±3
During pacing	48±5	89±9]*	44±4	14±3	3±1]*	14±3

*P < 0.01

Baseline gas tensions were similar in the normal and infarcted segments, but significantly different in the ischemic segments (P<0.01). Atrial pacing elicited significant changes in the ischemic segments but not in normal and infarcted segments. These data indicate that changes in $Pm0_2$ and $PmC0_2$ in response to atrial pacing enable the identification of viable ischemic myocardial segments which would benefit from revascularization, and therefore differentiating them from normal and non-viable segments which do not benefit from revascularization.

EFFECTS OF FLUOROCARBONS AND SUPPLEMENTAL OXYGEN ON ACUTE MYOCARDIAL ISCHEMIA ASSESSED BY INTRAMYOCARDIAL GAS TENSION MEASUREMENT
Robert E. Rude, M.D.; Dietmar H. Glogar, M.D.; Shukri F. Khuri, M.D.; Stephanie Karaffa, B.S.; Robert A. Kloner, M.D., Ph.D.; Leland C. Clark, Jr., Ph.D.; James E. Muller, M.D.; Eugene Braunwald, M.D., FACC; Harvard Med. School/Peter B. Brigham Hosp. Boston, MA

Although fluorocarbons (FC), 0_2 carrying compounds which are effective as blood substitutes, have been shown to reduce myocardial infarct size, it is unknown whether they have a beneficial effect on myocardial gas tensions. We studied 27 open-chest dogs undergoing 2 sequential 5 min left anterior descending coronary occlusions (CAO) 75 min apart. 14 dogs were ventilated with 20% 0_2; after a control CAO, 7 of these dogs (Group A) received FC (40ml/kg) intravenously and 7 dogs received an equal volume of normal saline (NS) 60 min before CAO II. 13 dogs were ventilated with 100% 0_2; 7 of these dogs (Group C) received FC (40ml/kg) and 6 dogs NS before CAO II. Myocardial gas tensions were measured by mass spectrometry: $\Delta PmCO_2$ (mmHg) = rise in ischemic zone pCO_2 with 5 min CAO; $Pm0_2$ (mmHg) = ischemic zone $p0_2$ at the end of 5 min CAO. FC alone (Group A) led to a smaller rise in ischemic $pC0_2$ ($\Delta PmC0_2$ 21±5 during CAO I vs 15±2 during CAO II; $p < 0.05$) but did not effect $pm0_2$, while NS alone (Group B) had no effect. FC and 0_2 (Group C) led to both a smaller $\Delta PmC0_2$ (33±5 during CAO I vs 23±4 during CAO II $p < 0.05$) and a higher ischemic $Pm0_2$ (9±4 at the end of CAO I vs 22±7 in CAO II, $p < 0.05$), while NS + 0_2 (Group D) had no effect. We conclude that treatment with FC reduces acute ischemic injury with and without supplemental 0_2 ventilation. FC and 0_2 act synergistically; in combination they lead to increased $Pm0_2$ in the ischemic myocardium. Although numerous interventions have been shown to reduce myocardial tissue $\Delta PmC0_2$, this is the first intervention from our laboratory to improve myocardial $Pm0_2$.

HYPOTHERMIC RETROPERFUSION TREATMENT OF ACUTE MYOCARDIAL ISCHEMIA: EFFECTS ON CARDIAC FUNCTION AND INFARCT SIZE
Roberto Haendchen, MD; Noboru Aosaki, MD; Takahisa Uchiyama, MD; Xavier Escudero; Jeffrey Broffman, BA; Samuel Meerbaum, PhD, FACC; Eliot Corday, MD, FACC, Cedars-Sinai Medical Center, Los Angeles, California

To extend the viability of acutely ischemic myocardium, moderate hypothermia (H) was administered via the great cardiac vein along with diastolic retroperfusion in closed chest dogs with 6 hours occlusion of the proximal LAD coronary artery. Of 12 dogs, 6 served as untreated controls and 6 had H initiated 30 min postocclusion. Hemodynamics were monitored, cardiac function measured by two-dimensional echocardiography and myocardial necrosis evaluated by triphenyl-tetrazolium-chloride. Retroinfusate temperature was 18.7±.8°C. H treatment between 30 min and 6 hrs caused a significant ($p<.02$) drop in heart rate (from 104±10.7 to 91±9.1/min) and rate-pressure product (from 11298±680 to 7507±1526 mm Hg/min). LV stroke volume and systemic vascular resistance did not change significantly. No arrhythmias were encountered. Data on % change in LV ejection fraction (EF) from 30 min to 6 hrs and infarct size (% of LV) are listed (p values vs controls).

	Change in LV EF	Infarct Size
CONTROL DOGS	-16.0±27.9%	21.1±4.8%
H-TREATED DOGS	+32.4±5.8% (p<.01)	3.5±3.6% (p<.001)

Echo analysis of the LV section indicated a 27.2±29.7% increase in systolic percent area change during H compared to a 62.3±4.3% decrease during the equivalent period in control dogs ($p<.01$). CONCLUSION: During a 6-hr coronary occlusion in closed chest dogs, moderately hypothermic retroperfusion significantly extended myocardial viability and improved global as well as regional LV function. Retrograde delivery of hypothermia may be a safe and effective technique for treating acutely ischemic myocardium.

MECHANISM OF LOW OUTPUT IN EXPERIMENTAL RIGHT VENTRICULAR INFARCTION. James A. Goldstein, MD, Gus J. Vlahakes, MD, Edward D. Verrier, MD, Nelson Schiller, MD, FACC, John V. Tyberg, MD, PhD, FACC, Kanu Chatterjee, MD, FRCP, FACC. Cardiovascular Res. Inst., Univ. of Calif., San Francisco.

RV infarction (RVI) can result in decreased CO. To elucidate the mechanism involved, selective RVI was produced in 15 dogs with the pericardium intact. CO, intrapericardial pressure (IPP) and RV and LV pressures were measured; stroke work (SW) and end-diastolic transmural pressures (TM) were calculated. Data were obtained before (Control) and after RVI and after subsequent pericardiotomy.

mean ± SEM	Control	RVI	Pericardiotomy
CO ($L \cdot min^{-1}$)	2.0±0.6	†1.3±0.5	‡1.8±0.5
RV SW ($g \cdot m \cdot m^{-2}$)	5.3±2.7	†2.1±1.5	3.3±1.1
RV TM (mm Hg)	1.0±1.3	*1.7±1.8	††6.2±1.6
LV SW ($g \cdot m \cdot m^{-2}$)	25.9±10.1	†11.8±6.8	**21.2±6.0
LV TM (mm Hg)	4.6±1.8	†2.0±1.9	††9.2±2.8
IPP (mm Hg)	4.7±1.5	†7.6±1.8	††0±0

Analysis of variance: Control vs RVI: *P<0.05, †P<0.001; Pericardiotomy vs RVI: ‡P<0.05, **P<0.005, ††P<0.001.

RVI resulted in RV failure as evidenced by decreased RV SW despite increased RV TM; LV SW decreased concomitantly with reduced LV TM, suggesting that low CO resulted from reduced LV preload. Two-dimensional echocardiography demonstrated marked RV dilatation and decreased LV size. IPP increased and equalization of ventricular diastolic pressures was noted. Subsequent pericardiotomy increased LV SW, LV TM, CO, and RV TM, with resolution of ventricular diastolic pressure equalization.

Low CO in RVI is due primarily to reduced LV preload resulting, in part, from depressed RV function. Elevated IPP, resulting from RV dilatation, further reduced LV preload and produced diastolic pressure equalization. Pericardiotomy improved LV filling and hence increased CO. The pericardium may thus play an important role in the pathophysiology of low CO in RVI.

EARLY AND LATE PROTEOLYSIS IN ACUTE MYOCARDIAL INFARCTION Roberto Bolli, MD, Richard O. Cannon, MD, Robert E. Goldstein, MD, FACC, Stephen E. Epstein, MD, FACC, NHLBI, Bethesda, Md.

Lysosomal proteases have been thought to play an important role both in the production and in the healing of acute myocardial infarction (AMI). However, the changes in proteolysis (PR) occurring in the evolution of AMI are unknown. Thus, control (C) rats underwent coronary artery occlusion (O); 2,6,24,48 and 72 hrs after O, slices were obtained from ischemic (IZ), normal (NZ) or border zone (BZ) myocardium and incubated for 1 hr in oxygenated or in anoxic Krebs-Ringer-HCO_3^- buffer. Cycloheximide was added (.5mM) to block protein synthesis. PR was measured by net tyrosine production (pmol/mg tissue, mean ±SE):

	2hrs(n=17)	6hrs(n=7)	24hrs(n=9)	48hrs(n=8)	72hrs(n=21)
NZ	92±13	-	86±11	102±16	114±8
BZ	-	-	192±31	401±46*	394±27*
IZ	77±7	33±11**	98±11***	262±23***	249±23***

(*=p<.02 vs 24hrs;**=p<.01 vs 2hrs;***=p<.001 vs 6 hrs) Thus, in AMI, PR follows a biphasic pattern: it decreases early, when irreversible damage develops, and later increases markedly both in the BZ and in the IZ, concomitant with the infiltration of inflammatory cells. To test the concept that this late rise in PR could be important in the healing of AMI, we gave methylprednisolone 50 mg/kg i.v. to 6 rats at 5 min after O and 50 mg/kg i.m. at 3,6,24 and 48 hrs after O: at 72 hrs PR both in BZ (225±56) and IZ (170±17) was significantly decreased (p< .02) relative to C. This inhibition of late PR may contribute to impaired healing of AMI reported when this steroid dose is given to rats. Our data suggest that lysosomal and, more generally, cellular proteases do not contribute to ischemic cell death but may play an important role in the healing phase of AMI.

PHARMACOLOGY: CONCEPTS IN THERAPY OF VENTRICULAR ARRHYTHMIAS
4:00-5:30

CHRONIC INTRAVENOUS INFUSION OF ANTIARRHYTHMIC DRUGS USING A TOTALLY IMPLANTED DRUG DELIVERY SYSTEM
Jeffrey L. Anderson, MD, FACC; Richard P. Donahue, BS; Marilyn E. Conlon, MA; Stanislaw Pasyk, MD; Phillip L. Stetson, PhD, MD; Arthur B. Simon, MD; William E. Burmeister, PhD; Elton M. Tucker, BS; Bertram Pitt, MD, FACC. University of Michigan, Ann Arbor, MI.

The success of antiarrhythmic therapy is in part limited by an inability to maintain therapeutic steady state plasma concentrations (Css) over time. A totally implantable, self-powered drug delivery system ("Infusaid", Metal Bellows Co., Sharon, MA) has recently become available. In order to establish the feasibility of this system to chronically deliver therapeutic doses of selected antiarrhythmic agents, we subjected it to both in vitro and in vivo testing. The Infusaid pump consists of a hollow titanium disk separated into 2 chambers by a bellows and powered by pressure of fluorocarbon vapor at 37°C. Pressure on the bellows forces infusate from the reservoir (35 or 50ml) at a constant rate through a filter and fine-bore silastic catheter positioned in the vena cava. During 3 months in vitro testing, procainamide (P), and bretylium (B), were found suitable for chronic delivery. Delivery of lidocaine (35%,70%) was limited by high viscosity and corrosion of steel elements. In vivo feasibility studies in dogs lasting 2 weeks were carried out with P and B. The pump was placed in a subcutaneous abdominal pocket in 4 animals. P (0.5 g/ml), delivered at 4 ml/d (70 mg/kg/d), provided mean Css of 5.3 mcg/ml. Css was attained by 8-24 hr. B (50 mg/ml), delivered at 8 ml/d (13 mg/kg/d), provided Css of 0.80 mcg/ml (range 0.41-1.49 mcg/ml). Css was attained by 24-48 hr. In contrast, oral B resulted in mean Css of only 0.19 mcg/ml in patients. In conclusion, chronic intravenous delivery of therapeutic B and P is feasible and suggests further study in man.

EFFECT OF PROSTACYCLIN ON VENTRICULAR ARRHYTHMIAS AND INTRACARDIAC CONDUCTION IN MYOCARDIAL ISCHEMIA
Thomas L. DeBauche, M.D., Tedd A. Brandon, B.S., Lair G.T. Ribeiro, M.D., Kevin Holyfield, Richard R. Miller, M.D., FACC, Baylor College of Medicine, Houston, Texas

Several of the prostaglandins have been shown to possess antiarrhythmic properties. To elucidate the effects of prostacyclin (PGI_2) on ventricular (V) ectopy in acute ischemia, 29 dogs undergoing proximal left anterior descending coronary artery occlusion (CAO) were randomized to PGI_2 (n=12) or control (C) (n=17). Occlusion site was equal (p=ns) in both groups. All had continuous ECG recordings and 11, His bundle electrography. PGI_2, .5-2.0 µg/kg/min began 15 min pre-CAO and continued 30 min post-CAO. Post-CAO, V ectopic beats per 1000 beats were reduced by PGI_2: C, 160±49; PGI_2, 63±27, (-60%; p<.02). V tachycardia (tach) episodes were similar: C, 24 in 17 dogs; PGI_2, 14 in 12 dogs (p=ns). However, in C, V tach resulted in V fibrillation in nine animals (53%) vs one (8%) in PGI_2 (p<.02). V tach features were examined: duration, C, 14±14 (SD) beats vs PGI_2, 6±10 (p=ns); cycle length, C, 203±49 msec vs PGI_2, 317±75 (p<.02). PGI_2 did not alter sinus rate (153±8 to 149±9 bpm) or HV intervals (36±2 to 35±2 msec) (both p=ns); AH was shortened 79±5 to 70±6 msec (p<.05). In eight dogs given a nitrate to lower BP equal to PGI_2, AH was unchanged. Thus, PGI_2 reduces total ventricular ectopy and tends to shorten AH conduction in acute myocardial ischemia. Of particular interest, PGI_2, while not preventing the occurrence of ventricular tachycardia, increases the V tach cycle length and attenuates the progression to ventricular fibrillation. Thus, PGI_2, in acute myocardial ischemia, markedly reduces the occurrence of ventricular fibrillation and mortality during the first 30 minutes following coronary artery occlusion.

MEXILETINE FOR RESISTANT VENTRICULAR TACHYCARDIA: COMPARISON WITH LIDOCAINE AND ENHANCEMENT OF EFFICACY BY COMBINATION WITH QUINIDINE. Henry J. Duff, M.D., Dan M. Roden, M.D., R. Kirby Primm, M.D., Edmund L. Carey, M.D., John A. Oates, M.D. and Raymond L. Woosley, M.D., Ph.D. Departments of Pharmacology and Medicine, Vanderbilt University School of Medicine, Nashville, TN.

Mexiletine (Mex) is a structural analog of lidocaine (Lid) with antiarrhythmic (AA) activity when given orally. We studied 12 patients (pts) with recurrent ventricular tachycardia (VT) nonresponsive (NR) to all conventional oral agents, assessing 1) the degree of correlation between response (R) to Lid and R to oral therapy with Mex, and 2) the R to quinidine (Q) combined with Mex in pts resistant to Mex and Q given separately. NR was defined as persistence of VT or <70% suppression of ventricular ectopic depolarizations (VED). Of the 12 pts, 10 had ischemic heart disease, 7 had required repeated cardioversions due to VT, and the remaining 5 had symptomatic recurrent nonsustained VT. VED and VT frequency were quantitated before therapy, during infusions of Lid at plasma concentrations in the usual therapeutic range, and during trials of gradually increasing dosages of Mex. If pts were NR to Mex, Q was added. Results:

	Lid R	Lid NR	5/12 Pts NR to Mex Alone:	Mex	Mex+Q	Q
Mex R	5	2	Pts R/Pts NR	0/5	5/5	0/5
Mex NR	0	5	%↓VED($\bar{x}$±SD)	65±16	94±4	56±16

VT suppression continues during outpatient therapy for a mean of 5 months (SD=2). All pts responding to Lid responded to Mex; however, lack of R to Lid did not preclude a R to Mex in two pts. The addition of Q, a type I AA agent, enhanced the efficacy of Mex, a type II AA agent, suggesting that combination therapy with drugs having different electrophysiologic properties may improve AA efficacy.

LACK OF EFFECTIVENESS OF BRETYLIUM IN PAROXYSMAL SUSTAINED VENTRICULAR TACHYCARDIA

Robert Bauernfeind, MD, FACC; Steven Swiryn, MD, FACC; Edwin Palileo, MD; Boris Strasberg, MD; Elise Duffy, MD; Daniel Scagliotti, MD; Kenneth Rosen, MD, FACC, University of Illinois, Chicago, Illinois.

Bretylium tosylate (BRET) has been recommended for use in patients (pts) with drug-resistant ventricular tachycardia (VT) or fibrillation (VF). Programmed stimulation (PS) is a technique for evaluating prophylactic drug effectiveness in paroxysmal sustained VT. In this study, we utilize PS to evaluate BRET in 6 consecutive pts with recurrent paroxysmal sustained VT (two pts also had VF). These pts, aged 21 to 67 (mean 56) yrs, had remote infarctions (5 pts) or cardiomyopathy (1 pt). All 6 pts had inducible sustained VT during control PS. Intravenous (IV) BRET (10 mg/kg) was infused over 30 min, and PS repeated 30 min after infusion. In 5/6 pts, PS induced sustained VT of identical morphology and similar cycle length (CL) to control VT (CL 324 ± 15 with BRET vs 340 ± 17 msec in control) (NS). In 1/6 pts, VT could not be induced after IV BRET. This pt was subsequently studied on oral BRET. After 48 hours of 1.0 gm BRET q 6 hours, this pt had inducible sustained VT of identical morphology and similar CL to control VT (CL 330 with BRET vs 340 msec in control). A second oral study (48 hours of 1.6 gm q 6 hours) revealed induction of sustained VT of new morphology (CL 320 msec). All pts tolerated control VT well. Three pts tolerated BRET VT poorly (hypotension), one of these pts requiring emergent cardioversion. In conclusion, BRET had little effect on induction (and CL) of paroxysmal sustained VT. Our results imply that IV or oral BRET would be of little value in this arrhythmia, and could be deleterious because of hypotension.

PROTECTION AGAINST VENTRICULAR FIBRILLATION BY CALCIUM ANTAGONISTS. Francis T. Thandroyen, MRCP; Louise Higginson, BSc; Christian W. Hamm, MD; Lionel H. Opie, MD, FACC. MRC Ischaemic Heart Disease Research Unit, University of Cape Town, South Africa.

To investigate the possible role of calcium ions in the genesis of ventricular fibrillation, we studied the effects of verapamil, nifedipine and diltiazem on the ventricular fibrillation threshold (VFT) of isolated perfused rat hearts before and after coronary artery ligation. The highest concentration that did not cause heart block was used. Results were (Means ± SEM for 6 hearts):

	Ventricular fibrillation threshold mA			
	Pre-ligation	2 min post ligation	5 min post ligation	15 min post ligation
Control	8 ± 1	6 ± 1	3 ± 1	2 ± 0.5
Verapamil 1.5×10^{-7}M	12 ± 2	8 ± 1	7 ± 1**	5 ± 0.5**
Verapamil paced	14 ± 2*	13 ± 1**	10 ± 2**	7 ± 2*
Nifedipine 1×10^{-6}M	17 ± 4**	12 ± 2	9 ± 1***	5 ± 1***
Diltiazem 1×10^{-6}M	10 ± 2	8 ± 1	5 ± 0.5	3 ± 0.5*

*P<0.05 **P<0.02 ***P<0.001 versus control hearts

Thus verapamil and nifedipine protected against the fall in VFT almost throughout the ischemic period, while diltiazem showed protection only at 15 min. These favourable effects were not mediated by changes in coronary flow, heart rate, tissue metabolism (high energy phosphates), nor by decreased tissue cyclic AMP. We conclude that: (1) protection against VF occurred as result of inhibition of transmembrane calcium flux, and (2) that calcium ions play an important role in the genesis of VF in our model.

IMPROVED SURVIVAL IN SUDDEN DEATH/VENTRICULAR TACHYCARDIA PATIENTS WITH THERAPEUTIC ANTIARRHYTHMIC DRUG LEVELS. Stephen C. Vlay, MD; Clayton H. Kallman, Sc.M; Philip R. Reid, MD, FACC. Johns Hopkins University, Baltimore, Maryland.

Fifty six patients (pts) with hypotensive ventricular tachycardia or sudden death/ventricular fibrillation refractory to conventional drugs were treated with aprindine (Ap) until hypotensive ventricular tachycardia was abolished. Failure was defined by death or syncope. Dose adjustment of Ap was complete after an average of one month. Initial blood levels (IBL) (between day 25-50 post-entry) were available on 43 pts. Another 13 had no level during this period but did have prior and/or subsequent levels. Based on the initial blood level, pts were divided into 2 groups: Ap>1.5 ug/ml and Ap≤1.5 ug/ml. Range of deaths for the 43 pts was 62-1583 days with the median time to death 690 days for IBL>1.5 ug/ml and 251 days for IBL≤1.5 ug/ml. Kaplan Meier Survival Curves (KMSC) were plotted and tested by the generalized Wilcoxon Test for differences in survival. Survival of the IBL>1.5 ug/ml group was consistently better than the IBL≤1.5 ug/ml group ($p<.03$). To examine variability over time, average blood level (AvBl) was calculated for all 56 pts using all levels post day 26. KMSC again showed better survival for the AvBl >1.5 ug/ml group ($p<.029$). Ten known predictors of survival (sex, # infarct, congestive heart failure, angina, diabetes, hypertension, smoking, family history of sudden death, a lesion of the left anterior descending proximal to the first septal perforator, abnormal contractility in the posterobasal segment of the left ventricle) showed no difference in distribution between IBL>1.5ug/ml and IBL≤1.5 ug/ml groups. Thus improved survival was observed with therapeutic levels of Ap >1.5 ug/ml in this high risk group.

PEDIATRIC CARDIOLOGY—CLINICAL STUDIES
4:00-5:30

COLLABORATIVE STUDY OF BLADE ATRIAL SEPTOSTOMY

Sang C. Park MD, FACC; William H. Neches MD, FACC; Charles E. Mullins MD, FACC; Robert A. Mathews MD; Frederick J. Fricker MD; Lee B. Beerman MD, Cora C. Lenox MD, FACC, J. R. Zuberbuhler MD, FACC
University of Pittsburgh School of Medicine and Children's Hospital of Pittsburgh, Pittsburgh, Pa.

During the past 3 years, 5 institutions have collaborated in an evaluation of the efficacy of blade atrial septostomy (BS). Forty-three patients underwent BS, including 25 with transposition of the great arteries (TGA), 10 with mitral atresia complex (MAC), 3 with tricuspid atresia (TAT) and 5 with miscellaneous anomalies. Ages ranged from 1 day to 12 years. Twenty-nine (67%) were under 6 months of age, 6 between 7 and 12 months and 8 were older than 1 year at the time of BS. Clinical improvement occurred in 20 of 25 (80%) patients with TGA. In 2 patients a large atrial septal defect (ASD) was created by the procedure but adequate mixing did not occur and early Mustard operation was performed. Three other patients had borderline size ASD prior to BS and the blade did not engage the interatrial septum (IAS). Seven of 10 patients with MAC had a good result with BS. In 2 patients in this group the LA was too small to permit extension of the blade. Three patients with TAT and the 5 patients in the miscellaneous group had an excellent result. Immediate improvement occurred in 81% of the 43 cases. Four patients had intact IAS and BS was successfully performed by transseptal technique. Among 17 patients who have undergone follow-up evaluation of interatrial opening (IAO) re-stenosis of the IAS was observed in 3 patients 10 to 22 months after the BS. There was a single mortality, a result of laceration of the left atrial wall. Minor complications were observed in 3 patients. BS is an effective palliative procedure, even with thickened IAS or with an intact IAS.

HEMODYNAMIC EFFECTS OF HYDRALAZINE IN INFANTS WITH LARGE VENTRICULAR SEPTAL DEFECT.

Robert H. Beekman, M.D., Albert P. Rocchini, M.D., Amnon Rosenthal, M.D., F.A.C.C., University of Michigan Medical School, C.S. Mott Children's Hospital, Ann Arbor.

To evaluate the effects of acute afterload reduction, Hydralazine (HZ, .2 mg/kg) was administered at cardiac catheterization to 6 infants with large ventricular septal defect (VSD). Age ranged from 2.5 to 11 (mean 5.3) months. Prior to HZ and 5, 15, 25, and 35 minutes after HZ the following were measured: Ao, pulmonary capillary wedge (PcW), PA, RA, SVC pressures and saturations, heart rate (HR), and oxygen consumption (VO2). Hemodynamic effects were noted 5 minutes post-HZ but were most pronounced 35 minutes post-HZ. Pre-HZ baseline data were therefore compared to 35 minute post-HZ values. Pulmonary flow (Qp) did not change while systemic flow (Qs) increased significantly (4.6 ± 0.3 to 6.6 ± 0.5 L/min/m^2, $p<.01$, mean $\pm$ SEM). The Qp/Qs ratio decreased (3.5 ± 0.4 to 2.3 ± 0.3, $p<.01$) as did the absolute left to right shunt (11.1 ± 1.5 to 8.2 ± 1.4 L/min/m^2, $p<.05$). As expected HZ caused a significant decrease in systemic resistance (Rs, 13.5 ± 0.7 to 9.6 ± 0.8 units, $p<.001$). Pulmonary resistance, PcW pressures, HR, and VO2 did not change following HZ. A small but significant decrease in RA pressure (4.2 ± 0.7 to 2.3 ± 0.7 mmHg, $p<.05$) was observed. In conclusion, HZ caused a significant increase in Qs, and a significant decrease in both Qp/Qs ratio and absolute left to right shunt in 6 infants with large VSD. These effects appear to be related to the decrease in Rs which occurred with HZ. This is in contrast to our previous work documenting hemodynamic deterioration with nitroprusside in a similar group of infants with VSD. Thus, HZ may be beneficial in the management of infants with large VSD.

SAFETY AND EFFICACY OF SHORT AND LONG TERM VERAPAMIL THERAPY IN CHILDREN WITH TACHYCARDIA

David Sapire, MD; Margo Schleman, MD; Anna O'Riordan, MD; Iain Black, MD, Temple University and St. Christopher's Hospital for Children, Philadelphia, PA and The University of Texas Medical Branch, Galveston, Texas

Seven children aged 3 months to 11 years have been treated with Verapamil (V) because of resistant, symptomatic supraventricular tachycardia (SVT), or because of complications of conventional therapy. Two of 3 patients with congenital heart disease were post-operative. The others had no gross cardiac anomalies. Three patients had SVT with WPW syndrome, 3 had ectopic SVT and 1 had atrial flutter (AF). Intravenous V was given in a dose of 0.15 to 0.25 mg/kg in 6 patients, 4 of whom converted successfully. One patient was placed on oral V only. Treatment failed in the patient with AF and one patient with WPW and a wide QRS tachycardia. Five patients were placed on continuing oral therapy. One patient died of post-operative complications while on V. Four patients have remained on oral V for 1 to 4 years at this time. The dose is 80 mg., 6 or 8 hourly depending upon response. Two of these have ectopic SVT which recurs when therapy is stopped. In the 2 with WPW and SVT, one patient has had no recurrences and in the other attacks have decreased from 1-2/week to 1-2/month. The duration of these attacks has also diminished. There have been no side effects of chronic drug administration. None of the 6 patients who received intravenous V showed any untoward effects during administration. Our experience indicates that V which so far has not been used extensively in children is an effective and safe anti-arrhythmic drug capable of controlling both ectopic and re-entrant SVT when conventional methods fail. The presence of underlying congenital heart disease should not be contraindication to its use.

CLINICAL AND ELECTROPHYSIOLOGIC PREDICTION OF NEED FOR PACEMAKER INSERTION IN CHILDREN WITH CONGENITAL COMPLETE ATRIOVENTRICULAR BLOCK

Peter P. Karpawich, MD; Paul C. Gillette, MD, FACC
The Lillie Frank Abercrombie Section of Pediatric Cardiology, Baylor College of Medicine, Houston

The criteria for pacemaker insertion (PM) in patients with congenital complete AV block (CCAVB) have not been defined. In an attempt to define such criteria we evaluated 22 children with CCAVB, ages 1 day-14y (median 7y) with surface ECG, treadmill exercise testing (TM) noting change in resting heart rate (HR) and prevalence of ventricular ectopy (PVC) and intracardiac electrophysiologic studies (EPS) including identification of site of block, corrected pacemaker recovery time (CPRT), and His to ventricle interval (HV). Patients were followed 1-19y (median 6y), noting age of onset of any syncopal episodes (SX). Associated congenital heart defects (CHD) were found in 5/22 children. Site of block was localized to the AV node (AVN) in 17/22, His Bundle (HB) in 3/22, below HB (BHB) in 1/22, and was unknown in 1/22 patients. Data are as follows:

	No.	BLOCK SITE			HR	CHD	SX	EPS		TM		
		AVN	HB	BHB	(Md			CPRT-msec <2000	>2000	No.	%Δ HR (mean)	PVC
PM	10	8	1	1	45	2/10	6/10	-	5/9	5/10	100	2/5
NO PM	11	9	2	-	60	3/11	1/11	2/9	2/9	6/11	130	1/6

The HV was normal in 20/20 patients. Evaluation of the 7 SX patients revealed AVN block in 6/7, 3 of whom had SX at 2y of age. The HR in all SX patients was <52BPM whereas no patient with HR>52BPM experienced syncope ($p<0.01$). CPRT estimation was performed in 4/7 SX patients; all were >2000msec. However, 3 asymptomatic patients also had CPRT>2000msec. The %Δ in HR during TM was not significantly different between sites of block. We conclude: 1. Localization of CCAVB to the AVN does not mitigate against syncope; 2. The best single predictor of SX either clinically or during EPS was a low HR; 3. EPS may be of little benefit as neither site of block nor CPRT are valid predictors of SX; 4. TM is of little benefit in predicting site of block or SX.

MULTIPLE ATRIOVENTRICULAR NODAL PATHWAYS - A NEW ELECTROPHYSIOLOGICAL PHENOMENON IN CHILDREN

Alfonso Casta, MD; Grace S. Wolff, MD, FACC; Dolores Tamer, MD, FACC; Ashok V. Mehta, MD; Otto L. Garcia, MD, FACC; Katharine G. Smith, BSN; Henry Gelband, MD, FACC, University of Miami School of Medicine, FL and University of Texas Medical Branch, Galveston, TX.

Functional longitudinal dissociation of the atrioventricular node into multiple pathways has been demonstrated in adults with reentrant supraventricular tachycardia. Atrial extrastimulus (AES) technique disclosed multiple pathways in 4 children with heart disease; none had dysrhythmias. AES were coupled to sinus and paced rhythms until atrioventricular nodal effective and functional refractory periods were reached. Multiple pathways were identified by sudden increases in atrioventricular conduction which resulted in discontinuous atrioventricular nodal curves in these children. Four pathways were shown in one patient during AES coupled to sinus; and 3 during AES coupled to paced rhythms. Three pathways were shown in 2 patients during AES coupled to sinus; and 2 pathways during AES coupled to paced rhythms. Three pathways were shown in 1 patient during AES coupled to paced rhythms; and none during sinus. The effective refractory period of the fastest pathways ranged between 290 and 455 msec; functional refractory periods between 340-520 msec. The effective refractory periods of the slower pathway ranged between 260-360 msec; functional refractory periods between 400-665 msec. Atrial echoes or supraventricular tachycardias were not induced. In conclusion, despite the foundation for supraventricular tachycardia and contrary to the adult patient, multiple pathways may be only a curious finding in children since dysrhythmias could not be induced nor clinically observed.

SURGERY FOR ACQUIRED VALVULAR HEART DISEASE
4:00-5:30

HEMODYNAMIC RESULTS FOLLOWING AORTIC VALVE REPLACEMENT WITH THE HANCOCK STANDARD ORIFICE BIOPROSTHESIS

A. Michael Borkon, M.D., Charles L. McIntosh, M.D., Michael Jones, M.D., Lewis C. Lipson, M.D., Kenneth M. Kent, M.D. and Andrew G. Morrow, M.D., Clinic of Surgery, National Heart Institute, Bethesda, Maryland

In order to improve hemodynamic results, aortic annulus enlargement has been recommended as an adjunct to valve replacement with the Hancock bioprosthesis. In order to determine a need for this additional procedure, postoperative cardiac catheterization data from 73 patients were reviewed. All patients underwent aortic valve replacement with Hancock standard orifice bioprostheses; annulus enlargement was not employed. Postoperatively, all but 2 patients were NYHA Class I or II. Peak systolic gradient (PSG), cardiac index (CI), body surface area (BSA), and effective valve orifice area (EOA) were determined. Resting data, mean ± SEM, were:

Size	No⁰	BSA(M^2)	PSG (mm Hg)	EOA (Cm^2)
21	15	1.63±0.03*	10±3†	1.27±0.17#
23	25	1.83±0.04	7±2	1.46±0.11
25	20	1.92±0.04	7±2	1.72±0.20
27	13	1.92±0.05	5±3	1.97±0.06

*=p<0.001 21 vs 23,25,27, †=N.S., #=p<0.05 21 vs 25,27

CI (2.6 ± 0.1 L/min/m^2) and EOA index (0.86±0.05 Cm^2/m^2) were similar for all sizes. Isoproterenol infusion (15 pts) increased PSG to a mean of 44 mm Hg (range 10-85) independent of valve size. Residual PSG or small EOA did not preclude satisfactory clinical improvement. Small diameter Hancock bioprostheses demonstrate acceptable clinical and hemodynamic function when limited to patients with small BSA. In these instances annulus enlargement is rarely necessary.

THE EFFECT OF AGE AND CYANOSIS ON THE PROTEIN BINDING OF QUINIDINE IN THE PEDIATRIC PATIENT.

Arthur S. Pickoff, MD, Kenneth M. Kessler, MD, FACC, Grace S. Wolff, MD, FACC Dolores F. Tamer, MD, FACC, Otto L. Garcia, MD, FACC, Henry Gelband, MD, FACC. Department of Pediatrics and Medicine, University of Miami School of Medicine, Miami, Florida.

Quinidine (Q), an antiarrhythmic agent utilized to treat arrhythmias in the pediatric age group, has been shown to be highly bound to serum protein in the normal adult patient (pt)(unbound drug = 10% of total serum Q). Since only the unbound Q is free to act upon the myocardium, as well as at sites of metabolism and excretion, differences in the protein binding of Q in the pediatric pt could result in alterations of the clinical pharmacology of Q. In order to study the protein binding of Q in children, serum samples were obtained from 6 normal newborn infants (Group I), 6 infants ages 8-18 months (Group II), 10 pts with acyanotic congenital heart disease (CHD) ages 2-11 years (Group III) and 5 pts with cyanotic CHD ages 9-19 years (Group IV). Quinidine (2 mcg/ml) was added to the pt's serum and an ultrafiltrate obtained. The ratio of Q in ultrafiltrate to serum was determined by spectrofluorophotometry and used to calculate % free Q. The % free Q in Group I was 39.2 ± 10.8; Group II 21.3 ± 7.4 and Group III 14.2 ± 5.4, demonstrating increased protein binding with age ($p < .001$). The pts with cyanotic CHD (Group IV) had significantly greater % free Q than pts with acyanotic CHD (Group IV)(33.7 ± 12.8 vs 14.2 ± 5.4, $p < .001$). We conclude that the protein binding of Q is diminished in the young pediatric pt as well as in pts with cyanotic CHD and that this may result in alterations of Q pharmacokinetics and pharmacodynamics in these patients.

CALCIFICATION OF CARDIAC VALVE BIOPROSTHESES: HISTOLOGIC, ULTRASTRUCTURAL, AND BIOCHEMICAL STUDIES IN A SUBCUTANEOUS IMPLANTATION MODEL SYSTEM.

Michael C Fishbein, MD, FACC, Robert J Levy, MD, Aws Nashef PhD, Victor J Ferrans, MD, PhD, FACC, Lyle C Dearden, PhD, Arden P Goodman, Alain Carpentier, MD, PhD. Cedars-Sinai Med Ctr, L.A., CA, Children's Hosp Med Ctr, Boston, MA, Amer Edwards Labs, Santa Ana, CA, and Hosp Broussais, Paris, France.

To study the process of calcification(Calc) in bioprostheses, 120 glutaraldehyde-treated porcine aortic valve leaflets(PVLs) were implanted subcutaneously in rabbits and removed 1 day to 6 months(mo) later; morphologic findings were correlated with biochemically determined levels of calcium(Ca++) and γ-carboxyglutamic acid (Gla), a vitamin K dependent Ca++ binding amino acid known to be present in tissues with pathologic Calc. In PVLs explanted from day 1 to 7, which showed only inflammatory infiltrates, Ca++=382-465, and Gla=.32-.56 (these and all subsequent values in nm/mg protein). In PVLs explanted at 1-1.5 mo, Calc of PVLs and degeneration of collagen were noted histologically and ultrastructurally, and increased with time as did Ca++ and Gla levels; at 5-6 mo Ca++=7300-8060 and Gla=2.0-3.1. In PVLs implanted in patients 22 to 64 mo, Ca++=7527-30441 and Gla= 4.3-18.3. Ca++/Gla molar ratios in PVLs from this experimental system explanted at 5-6 mo also were comparable to those in clinical specimens explanted from 22 to 64 mo. In conclusion, in this experimental system, structural and biochemical alterations, particularly those related to Calc, are similar to those observed in PVLs explanted from patients, but occur much sooner. As with pathologic Calc of other tissues, progressive Calc was accompanied by increased Gla levels, suggesting that Gla plays an important role in Calc of PVLs. This model allows rapid comparative evaluation of large numbers of PVLs maintained under identical host conditions.

EXPERIENCE WITH PRIMARY FAILURE OF PORCINE BIOPROSTHETIC CARDIAC VALVES

Donald J Magilligan,Jr MD, Steven Palmisano,David Smith, BS, Paul Stein,MD, Henry Ford Hospital, Detroit, Mi

Follow up on 587 porcine bioprosthetic cardiac valves inserted from October 1971 to June 1980 was completed with only four patients lost to follow up. Primary valve failure occurred in 27 valves. Primary failure was defined as valvular stenosis or insufficiency documented by tissue degeneration in the explanted valve without histologic or bacteriologic evidence of infection. The incidence of primary failure was:at five years - 4%±1.2 S.D.; at six years - 7%±1.8, at seven years - 13%±2.5, at eight years - 19%±4.1 and at eight and one-half years - 25%±7.1. There was no significant difference in primary failure between the aortic or mitral position, male or female, patients anticoagulated or not,or valves rinsed in antibiotics or not.At eight years the failure rate in patients ≥ 35 years (10%±2.7 S.D.) was significantly less than in patients < 35 years (61%±15) (p=0.0003).Analysis of valve position with respect to age showed that mitral valves in patients < 35 years had a significantly higher rate of failure (70%±17) than mitral valves in patients ≥ 35 (9% ±3) or than aortic valves in either age group (13%&11%) (p=0.0005). Echocardiography showed cusp thickening with duration of implantation and prior to tissue failure. Phonocardiography showed the dominant frequency of the bioprosthetic sound became higher with the duration of implantation and mimicked native valve stenosis suggesting progressive cusp stiffening. Eight and one-half year experience with porcine bioprosthetic valves shows primary failure occurs mainly in the mitral position in patients < 35 years. Specific factors leading to failure in these patients and to sporadic failure in others requires further investigation.

ECHOCARDIOGRAPHIC ASSESSMENT OF THE ST. JUDE MITRAL PROSTHESIS.

Martin St. John Sutton, MD, Raymond Roudaut, MD, Paul Oldershaw, MD, Nathaniel Reichek, MD, Derek Gibson, MD, Hospital of the University of Pennsylvania, PA

The ideal mitral prosthesis is 1) non-obstructive, 2) non-thrombogenic and, 3) durable. Since only long-term follow-up will provide answers to 2 and 3, regarding the St. Jude prosthesis, we assessed 1 by determining the effects of this all-pyrolite carbon valve upon LV filling characteristics. We measured the peak rates of increase in LV dimension, (peak filling rate), and the duration of the rapid diastolic filling period using computer-assisted analysis of the LV echograms in 27 patients with St. Jude mitral valves. To elucidate how obstructive the St. Jude valve was compared to other prostheses, we contrasted the results with similar data obtained from 30 patients with Starr-Edwards(SE), 30 with Bjork-Shiley(BjS) mitral valves, and 20 normal subjects. All patients were operated upon for either rheumatic or degenerative mitral valve disease. Echoes were obtained 3 months postop.

	Normal (20)	St.J (27)	BjS (30)	SE (30)
Peak LV filling rate.(cm/sec)	14.5±2.3	13.2±3.4	105±4.2	7.4±3.0
Rapid filling period.(ms)	160±50	165±45	180±80	295±110

Peak LV filling rates in patients with St. J. valves were normal and significantly greater than in those with SE($p<.001$) or BjS ($p<.02$) prostheses. However, the duration of the rapid filling period was similar in patients with St. J and BjS valves, but significantly shorter than in those with SE valves. We conclude that 1) in patients with St. J valves LV filling was similar to normal, 2) the St. J. was significantly less obstructive to LV filling than the SE or BjS, due to its low profile, 90° leaflet opening angle, and its maximal orifice to valve diameter.

LONG TERM RESULTS OF TRICUSPID VALVE REPLACEMENT - THE PROBLEM OF LATE THROMBOSIS

John J. Morgan, F.R.A.C.P., F.A.C.C., Charles W. Thorburn, M.R.C.P., St. Vincent's Hospital, Sydney, Australia.

The occurrence of a high incidence of late thrombosis of tricuspid valve prostheses had led to a complete followup of all patients who have undergone this operation at our institution. The group of 71 patients consisted of one single, 32 double, and 37 triple valve replacements. Valve types used were : from 1966-71, 27 Starr-Edwards model 6102 (SE); from 1971-75, 32 Bjork-Shiley (BS); from 1975-76, 8 Lillehei-Kaster (LK); and from 1976-80, 10 Porcine-Heterograft valves (PX). Operative mortality was 10%. Actuarial survival at 5 years was 72%, and at 13 years, was 50%. The type of valve used, or the number of valves replaced did not alter the survival. Complications per patient year followup were : endocarditis 0.5%, embolism 3.2% (fatal 0.2%), haemorrhage 5.6% (fatal 0.7%), permanent pacing 1.5%, and tricuspid valve thrombosis (TVT) 2.2%. There were 8 with TVT in 40 patients with tilting disc valves (BS & LK) and one in 27 patients with SE valves ($P<0.05$). No PX valves thrombosed in a shorter followup. Presentation in the 9 patients was insidious, with oedema and breathlessness. There was an elevated JVP present in 9, tricuspid diastolic murmur in 8, and reduced valve sounds in 5. Thrombolytic therapy was successful in one patient and failed in a second. Reoperation was performed in 8 patients with no mortality. It is concluded that there is a continuing high morbidity and mortality with tricuspid valve replacements. Obstructing thrombosis is common with tilting disc prostheses, but not with SE valves. Reoperation can be performed at low risk.

REGURGITATION OF PROSTHETIC HEART VALVES: DEPENDENCE ON HEART RATE AND CARDIAC OUTPUT.

Kevin C. Dellsperger, David W. Wieting, Ph.D., Debra A. Baehr, Robert J. Bard, Jean P. Brugger, Earl C. Harrison, M.D., F.A.C.C., LSU School of Medicine, Shreveport, LA

Prosthetic heart valves exhibit retrograde flow and leakage; however, no well controlled study to evaluate the influence of factors such as cardiac output and heart rate has been reported to date. To evaluate these factors, four clinically used prosthetic aortic valves (size 27 mm) were studied in a pulse duplication system at heart rates of 50, 80, 110 and 140 beats/min, cardiac outputs of 2, 4, 6 and 8 L/min, mean aortic pressure of 100 mmHg, and left atrial pressure from 1 to 20 mmHg. The valves studied were the St. Jude Medical (SJM), Björk-Shiley (BS), Björk-Shiley Convexo-Concave (BSC) and the Starr-Edwards Model 1260 (SE). The total backflow for the SJM aortic valve ranged from 9.8% (110 beats/min, 8 L/min) to 34.8% (110 beats/min, 2 L/min). For the BS aortic valve the total backflow ranged from 8.9% (110 beats/min, 8 L/min) to 35.0% (80 beats/min, 2 L/min). The BSC aortic valve had a total backflow that ranged from 9.5% (110 beats/min, 8 L/min) to 33.9% (140 beats/min, 2 L/min). The total backflow for the SE aortic valve ranged from 7.3% (140 beats/min, 6 L/min) to 19.3% (140 beats/min, 2 L/min). In addition to total backflow, the regurgitation was calculated in cc/stroke. The results were as follows: for the SJM, the range of backflow in cc/stroke was 6.6 to 13.3 with a mean of 9.2 cc/stroke, the BS had a range of 5.6 to 15.2 with a mean of 9.1 cc/stroke, the BSC had a range of 6.0 to 14.0 with a mean of 8.8 cc/stroke and the SE had a range of 2.3 to 6.4 with a mean of 4.2 cc/stroke. In summary, regurgitation associated with prosthetic heart valves can present a serious problem clinically, particularly with low cardiac output and tachycardia.

THE EFFECTS OF DRUG INTERVENTION IN ACUTE MYOCARDIAL INFARCTION IN ANIMAL MODELS
4:00-5:30

THE INFLUENCE OF NIFEDIPINE ON MYOCARDIAL BLOOD FLOW IN THE ISCHEMIC AND LATERAL BORDER ZONES

William S. Weintraub, MD; Shigehiko Hattori, MD; Jai B. Agarwal, MD; Monty M. Bodenheimer, MD, FACC; Vidya S. Banka, MD, FACC; Richard H. Helfant, MD, FACC, Presbyterian-University of Pennsylvania Medical Center, Phila.,Pa.

The effect of vasodilators on lateral border and ischemic zone myocardial flow (MBF) is controversial due to overlapping normal and ischemic tissue. Thus 12 dogs underwent carotid to left anterior descending (LAD) perfusion. A balloon perfusion microsphere technique was used to subtract overlapping normal zone MBF from ischemic zone MBF. Post LAD occlusion (PO), Nifedipine (Nif) was given IV 3ug/kg/min for 15 min. MBF was measured before and after Nif with microspheres. Transmural samples (5mm wide) were cut from remote normal (RNZ) and adjacent border normal (BNZ), border ischemic (BIZ), intermediate ischemic (IIZ) and central ischemic (CIZ) zones.Results: MBF in ml/g/min
*p<.05 compared to above, +p<.01 compared to left

	RNZ	BNZ	BIZ	IIZ	CIZ
PO	1.52	1.46	.490+	.217+	.172
NIF	1.95*	1.71*	.576+	.202+	.149
NZ subtracted from ischemic samples					
PO	1.52	1.41	.338+	.186+	.149
NIF	1.95*	1.71*	.324+	.132*+	.112*

Nif increased normal zone but not ischemic zone tissue MBF. After correction for overlapping normal tissue, Nif decreased IIZ and CIZ flow. In the BIZ the effect of Nif on MBF was not significant. The lateral border zone had higher MBF than ischemic zone even after correction for overlapping Nl zone tissue. Conclusions: (1) Nifedipine does not increase ischemic zone MBF (2)there is a distinct lateral border zone with intermediate MBF (3) drug effects on ischemic tissue flow cannot be assessed until corrected for overlapping normal tissue.

PROTECTION OF ISCHEMIC MYOCARDIUM BY DILTIAZEM

Christian W. Hamm*, MD; Francis T. Thandroyen, MRCP; Lionel H. Opie, MD, FACC. MRC Ischaemic Heart Disease Research Unit, University of Cape Town, South Africa and *Dept. of Cardiology, University of Hamburg, W. Germany.

We investigated the effect of a new calcium 'slow channel' blocker, Diltiazem, on the ischemic myocardium in the isolated working rat heart subjected to left main coronary artery ligation. Myocardial cellular damage was assessed by loss of lactate dehydrogenase (LDH), LV work as the sum of pressure and kinetic power, and LV efficiency as work divided by myocardial oxygen uptake (MVO_2). The results at 60 min post ligation were: (Mean ± SEM)

	Control	Diltiazem concentration $1x10^{-8}M$	$1x10^{-7}M$	$4x10^{-7}M$
	(n=12)	(n=7)	(n=13)	(n=11)
LDH (U/g/hour)	9.5±0.7	9.6±0.8	5.4±0.7***	3.8±0.7***
CO (ml/min)	21.3±2.4	19.5±1.7	32.4±3.4*	30.4±2.6*
Work (mJoules/s)	4.2±0.6	4.0±0.4	7.9±1.1**	6.9±0.7**
MVO_2 (ml/min)	89±3	92±11	105±7	104±8

*P<0.05 **P<0.01 ***P<0.0005

Diltiazem produced a concentration dependent reduction in myocardial LDH loss and maintained better mechanical function as manifest by improved CO and LV work. Enhanced myocardial function was not associated with increased MVO_2, thus efficiency of work was augmented. These changes did not correlate with tissue content of high energy phosphate or glycogen. These results indicate that Diltiazem exerts marked protection of the ischemic myocardium and may be potentially useful in the treatment of acute myocardial ischemia.

NITROPRUSSIDE IMPROVES CORONARY PERFUSION IN REGIONAL ISCHEMIA IN CONSCIOUS DOGS WITH NORMAL AND HIGH LEFT VENTRICULAR DIASTOLIC PRESSURE.

Malavalli A. Gopal, MD, William A. Neill, MD, John Oxendine, BA, VA Medical Center, Lemuel Shattuck Hospital and Tufts Univ. Sch. of Med, Boston, MA.

To determine the effects of nitroprusside(NP) on regional ischemia, experiments were done in 6 conscious dogs with balloon-cuff occluders implanted around the left anterior descending artery (LAD). Coronary blood flow (CBF) to LAD (ischemic) and left circumflex artery (LCF, non-ischemic)regions was determined by microsphere method during 5 minute periods of LAD occlusion with and without NP infusion (mean, 0.63 mg/min). The experiment was repeated 2 days later with high LVEDP produced by Inderal, Pronestyl and volume loading. Results:

	Heart Rate	Pressures(mm/Hg) Aortic mean	LVEDP	CBF (ml/min. 100g) LAD endo	LAD epi	LCF endo	LCF epi
Normal LVEDP							
Control	86	93	1	-	-	-	-
LAD occl.	103	88	5	16	17	70	55
LAD occl.+NP	134	59	1	24	21	103	98
High LVEDP							
Control	122	116	18	-	-	-	-
LAD occl.	124	93	23	22	24	113	83
LAD occl.+NP	122	62	5	31	28	171	134

With normal or high LVEDP, LAD occlusion caused marked ischemia in the LAD region, especially in the subendocardium (endo). NP infusion increased CBF to the endo and epicardium (epi) in the ischemic region about as much as in the non-ischemic region with either normal or high LVEDP. These results in conscious dogs contradict published data showing that NP worsens regional ischemia in anesthetized open-chest dogs. If we assume maximal arteriolar dilation in the ischemic region, its increased perfusion during NP suggests that the drug dilated coronary collaterals.

DIVERGENT EFFECTS OF INOTROPIC STIMULATION ON THE MECHANICAL FUNCTION OF THE ISCHEMIC AND THE SEVERELY DEPRESSED REPERFUSED MYOCARDIUM

Jean C. Mercier, MD, Ulf Lando, MD, Katsuo Kanmatsuse, MD, Michael C. Fishbein, MD, FACC, Kenji Ninomiya, MD, Gary Totten, H.J.C. Swan, MD, Ph.D. FACC, William Ganz, MD, FACC. Div. of Cardiology, Cedars-Sinai Medical Center, Los Angeles, CA

Extensive ischemic injury causes intractable pump failure unresponsive to inotropic support. Since severe depression of contraction is known to continue for hours and days following reperfusion we studied whether inotropic support, ineffective during ischemia, could improve the function of the severely depressed reperfused myocardium. Changes in segmental contraction during occlusion of the left anterior descending coronary artery (LAD) and following its reperfusion and the effect of 10 min infusions of dopamine at 8 ug/Kg/min on these changes were studied in 29 open-chest dogs by length gauges. During LAD occlusion, dopamine intensified the abnormalities of contraction. Following reperfusion alone contractile function either failed to improve or increased to only 10% of control (5 and 9 dogs respectively with 3 hours of LAD occlusion) or to 20% (15 dogs with 30 minutes of LAD occlusion). Dopamine increased segmental contraction in the reperfused myocardium to preocclusion level, except in 5 dogs in which the myocardium beneath of the length gauge was necrotic. Activation of the reperfused viable myocardium by dopamine resulted in a significantly greater augmentation of left ventricular stroke work following reperfusion than was the case during ischemia. Thus, while dopamine worsened segmental contraction during ischemia, it improved markedly the function of the severely depressed but viable myocardium following reperfusion. These data emphasize the importance of early reperfusion in the treatment of otherwise intractable pump failure, and because rapid intracoronary thrombolysis is now feasible they are of more than academic interest.

FAILURE TO REDUCE INFARCT SIZE IN THE RAT

George A. Pantely, MD; Hugh H. Kerr, University of Oregon Health Sciences Center, Portland, Oregon.

We evaluated ibuprofen (IBU), hydrocortisone (HC), and a reduction in blood oxygen affinity (↓BOA) to determine whether they could reduce infarct size in the rat. Under ether anesthesia, the following groups had cautery ligation of the left coronary artery: IBU (n=15), 12.5 mg/kg subQ given at 5 minutes, 3 and 6 hours post-myocardial infarction (p-MI); controls (n=7) received a similar volume of saline at the same times p-MI. HC (n=20) 50 mg/kg at 5 minutes p-MI: controls (n=7) were not given anything. ↓BOA induced by exposure to 11% oxygen for 24 hours followed by room air for the two hours prior to the cautery ligation (n=7); controls were handled in a similar manner except during the 24-hour period, they were exposed to room air (n=7). Exposure to 11% oxygen increased P_{50} to 43.1 torr compared to 38.7 torr for the control group. All rats were killed 48 hours p-MI. Hearts were weighed and infarct size determined by area and circumference methods. The results were:

	INFARCT SIZE (PERCENT OF LEFT VENTRICLE)	
Group	Area Method	Circumference Method
IBU	.48 ± .04 *	.54 ± .05 *
Control	.47 ± .03	.52 ± .05
HC	.47 ± .07 *	.52 ± .06 *
Control	.46 ± .02	.52 ± .03
↓BOA	.50 ± .03 *	.57 ± .04 *
Control	.48 ± .06	.53 ± .06

Results are mean ± SD (*=P > .1 for treated vs controls). IBU, HC and ↓BOA did not reduce infarct size in the rat after cautery occlusion of the left coronary artery. Reduction of infarct size may not be possible in the rat.

CALCIUM ANTAGONISTS: THEIR EFFECTIVENESS IN DECREASING THE OCCURENCE OF VENTRICULAR FIBRILLATION AND REDUCING INFARCT SIZE AFTER A CORONARY ARTERY OCCLUSION

Duarte B.Faria,MD;Tsutomu Iwasaki,MD;Takao Endo,MD; Wai-man Cheung,MS;Lair G.T.Ribeiro,MD;Peter R.Maroko,MD, FACC,Deborah Heart & Lung Foundation,Browns Mills, N.J.

Calcium antagonists(CaAnt)are a heterogeneous group of compounds that may act favorably on coronary artery spasm, arrhythmias and protect the ischemic myocardium.Our goal was to examine the effects of 3 very potent,new and dissimilar CaAnts on infarct size(IS)and on the occurence of ventricular fibrillation(VF)after coronary artery occlusion(CAO). Thus,103 open-chest dogs with CAO were randomly assigned to control(C,n=63)or treated(T,n=40)groups which were given intravenously,Bepridil(BEP,2.5mg/kg,n=13), Nisoldipine(NIS,0.1mg/kg,n=9),and methoxy-verapamil(D600), 1.2mg/kg,n=18)starting 15 min after CAO.To determine the zone of hypoperfusion(ZH)which is the area at risk that predicts IS,highly radioactive(8mCi)^{99m}Tc-labelled microspheres(15μ)were injected into the left atrium,1 min after CAO.After 6 hrs,the hearts were excised and cut into 20-25,3mm-thick slices,incubated in triphenyltetrazolium chloride(TTC)and autoradiographed.Their planimetry rendered,respectively,the extent of IS and ZH.In the control IS/ZH(% of ZH that necrosed)was 93.2±1.6% and it was reduced to 65.1±4.8% with BEP(p<.01),to 67.9±8.0% with NIS(p<.01) and to 47.8±5.2% with D600(p<.001).Treatment reduced mean arterial pressure, in 15 min,from 98±4 to 80±3mmHg(p<.001) and heart rate from 132±5 to 119±4 beats/min(p<.001). In C,13 out of 63 dogs(21%)had VF, between 15 min and 6 hr, while none of the 40 T had VF(χ^2=9.5,p<.001).IS/ZH was 93.2±1.6% in C and 60.2±3.5% in the T group,a reduction of 35%. Thus,calcium antagonists administration reduced the extent of infarctions and prevented ventricular fibrillation,suggesting an important role for these agents in the treatment of acute infarctions.

NUCLEAR CARDIOLOGY: EVALUATION OF THE PATIENT WITH ISCHEMIC HEART DISEASE
8:30-10:00

QUANTITATIVE ANALYSIS OF STRESS DISTRIBUTION AND WASHOUT OF Tl-201 MYOCARDIAL SCINTIGRAMS: SUPERIORITY OVER VISUAL ASSESSMENT FOR EVALUATION OF CORONARY ARTERY DISEASE

Jamshid Maddahi, MD; Ernest Garcia, PhD; Daniel Berman, MD FACC; Alan Waxman, MD; H.J.C. Swan, MD, FACC; and James Forrester, MD, FACC. Cedars-Sinai Med Ctr., L.A., CA.

Visual interpretation (VIS) of stress-redistribution Tl-201 scintigrams is suboptimal for evaluation of extent of coronary artery disease (CAD). Using a computer method, we have evaluated 118 patients (pts) with suspected CAD. Following development of criteria for abnormality in 31 normals (nls) and 20 CAD pts, quantitative analysis (QA) was applied prospectively to 22 nls and 45 CAD pts, of whom 41 had left anterior descending (LAD), 35 left circumflex (LCX), and 34 right coronary artery (RCA) stenosis (≥50%). Multiple view 10 minute planar Tl images were obtained 6, 40 and 240 minutes after exercise Tl injection. Circumferential profiles (CP) depicted the distribution (D) and % washout (W) of 60 6° myocardial arcs. Pt DCP's and WCP's were compared to the corresponding mean -2SD calculated from the initial 31 nls. QA was compared to consensus VIS to evaluate the sensitivity (Sn) and specificity (Sp) for overall detection of CAD and CAD in individual vessels. Results in the prospective group were as follows:

		CAD	LAD	LCX	RCA	TOTAL
QA	Sn	93%	80%*	63%*	94%*	79%*
	(Sp)	(91%)	(80%)	(90%)	(73%)	(81%)
VIS	Sn	91%	56%	34%	65%	52%
	(Sp)	(86%)	(93%)	(95%)	(86%)	(91%)

(*p<.05 QA vs VIS). QA correctly identified multi-vessel CAD in 76% pts in contrast to 47% by VIS (p<.01). Furthermore, for detection of 40 vessels with 50-75% stenosis, Sn was 70% and 35% (QA vs VIS) (p<.01). Thus, this new quantitative method is more Sn than VIS for evaluation of the extent of CAD without significant loss of Sp and is more Sn for detection of moderate stenosis.

QUANTITATION OF EXPERIMENTAL CANINE MYOCARDIAL INFARCT SIZE WITH TECHNETIUM STANNOUS PYROPHOSPHATE: A COMPARISON OF MULTIPINHOLE AND ROTATING SLANT HOLE EMISSION TOMOGRAPHY

Samuel E. Lewis, MD; Ernest M. Stokely, PhD; L. Maximillian Buja, MD, FACC; Robert W. Parkey, MD, FACC; James T. Willerson, MD, FACC, University of Texas Health Science Center, Dallas, TX.

Multipinhole (MH) and rotating slanthole (RS) tomographic estimates of myocardial infarct volume measured from 1 cm thick re-constructed slices were compared to multiview planar (2D) estimates of infarct area and to histologic measurements of infarct weight. Infarcts were produced in 21 anesthetized dogs by ligation of the proximal or mid-level branches of the LAD coronary artery. Planar, MP, and RS images were acquired concurrently 24-72 hrs postinfarction, 1-2.5 hrs following IV injection of 5-10 mCi (2.5 mg) technetium stannous pyrophosphate. Results:

DETECTION OF MYOCARDIAL INFARCTION		
21 Infarcts	14 Transmural	7 Nontransmural
1-23.0 gm,	7.1-23.0 gm,	1-9.0 gm,
mean = 10.1	mean = 12.9	mean = 4.5
2D 18/27 (85.7%)	14/14 (100%)	4/7 (57.1%)
MP 19/21 (90.5%)	14/14 (100%)	5/7 (71.4%)
RS 21/21 (100%)	14/14 (100%)	7/7 (100%)

CORRELATION WITH INFARCT WEIGHT (ALL INFARCTS)			
2D	r=0.72	y=0.34X+1.99	SE=±1.87 cm^2
MP	r=0.6	y=0.84X+2.36	SE=±6.37 cm^3
RS	r=0.89	y=0.97X+2.04	SE=±2.78 cm^3

The differences between MP and RS estimates of infarct size were significant (p<0.05). We conclude: (1) tomographic imaging may aid in detection of small infarcts and (2) RS appears to be superior to MP for infarct sizing.

CLINICAL UTILITY OF COLD PRESSOR RADIONUCLIDE VENTRICULOGRAPHY IN CORONARY ARTERY DISEASE.

Joshua Wynne, MD, FACC; B. Leonard Holman, MD, FACC; Gilbert H. Mudge, MD; Kenneth M. Borow, MD, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

To evaluate the utility of cold pressor radionuclide ventriculography (RVG) in coronary artery disease (CAD), 20 patients (15 with and 5 without CAD) underwent RVG before and during cutaneous exposure to iced water for an average of 4.8±1.1 minutes. Heart rate (64.9±10.3 to 67.7±10.6, $p<0.01$) and systolic blood pressure (117±18 to 143±30 mmHg, $p<0.0005$) rose, while left ventricular ejection fraction (LV EF) fell (59.1±16.4 to 52.1±16.5, $p<0.0025$). To establish the expected response of LV EF in normals to a pressor challenge alone, systolic blood pressure in 14 volunteers was raised with methoxamine to a level similar to that obtained during the cold pressor RVG (108±29 to 141±5 mmHg), and LV EF determined echocardiographically. LV EF declined 4±2.9%, thus establishing that LV EF might be expected to decline during the cold pressor RVG up to 10% (mean + 2 SD) merely on the basis of increased afterload, and independent of any possible effect of cold on coronary blood flow. Using the criterion of ≥10% decline in LV EF as the definition of an abnormal response, the cold pressor RVG had a sensitivity of only 33% (5/15) and a specificity of 80% (4/5) for the diagnosis of CAD. We conclude that while the cold pressor RVG may be of occasional value in patients unable to perform adequate levels of exercise, its low sensitivity suggests that it is inferior to exercise RVG or even exercise electrocardiography in the diagnosis of CAD.

THE REGIONAL EJECTION FRACTION IMAGE (REFI) - AN ACCURATE METHOD FOR THE DETECTION OF CORONARY HEART DISEASE

Hylton I. Miller, MB; Jack Baron, BSc; Shimon Braun, MD; Shlomo Laniado, MD, FACC; Tel Aviv Medical Center, Israel

Computer generated colour coded REFI's derived from ECG synchronised radionuclide cardiac blood pool imaging, using an Anger camera and a simple data processing system, were obtained in 101 patients undergoing coronary angiography, at rest and during handgrip exercise (HG). Angiographic diameter narrowing of ≥50% of 1 or more major coronary branches was considered diagnostic of CHD. A regional reduction of the colour coded REFI ≥12% during HG and regional ventricular border motion abnormalities (BMA) induced by HG was considered positive for significant CHD. 34/101 patients had normal coronary arteries (NCA), 32/67 (48%) of CHD patients had Q waves on ECG.

Results	No.	Positive HG REFI	Positive HG BMA
NCA	34	2/34 (6%)	2/34 (6%)
CHD	67	66/67 (99%)	52/67 (78%)

For detection of CHD using REFI sensitivity was 99% specificity 94% as compared to sensitivity of 78% and specificity of 94% for HG BMA. Changes in ejection fraction with HG did not allow differentiation of patients with CHD.

HG with REFI was a sufficient stress for detection of CHD. It is more sensitive than conventional assessment of BMA and may prove useful as a screening test.

COLD PRESSOR THALLIUM 201 MYOCARDIAL SCINTIGRAPHY IN DETECTION OF CORONARY ARTERY DISEASE: AN ALTERNATIVE TO EXERCISE SCINTIGRAPHY

Masood Ahmad,MD,FACC; Jerzy P. Dubiel,MD,FACC; Helmut Haibach,MD; Scott H. Goldberg; John F. Sanfelippo,MD; Richard H. Martin,MD,FACC, VA and University Hospitals, Columbia, Mo.

Thirty patients (pts) (age range 37-69 yrs) with chest pain syndromes underwent myocardial scintigraphy following injection of Thallium 201 during the standard cold pressor test (CPT). Twenty-three of 25 pts with cineangiographically confirmed coronary artery disease (CAD) developed transient perfusion deficits which normalized 4 hours later. All 5 pts without CAD (confirmed by coronary cineangiography) had normal scintigrams. In 22 pts who had previously performed a symptom-limited maximum exercise stress test, the sensitivity of exercise ECG in detecting ischemia was 88% and specificity 75% in comparison to a sensitivity of 89% and a specificity of 100% by CPT-Thallium 201 scintigraphy. Exercise Thallium 201 scintigraphy was performed in 14 pts. Eleven of 12 pts with CAD developed transient perfusion deficits following exercise and the 2 pts without CAD had normal scintigrams. Identical results were obtained by CPT-Thallium 201 scintigraphy in these 14 pts. Systolic pressure x heart rate was 103.0±17.0 at 2 minutes of CPT compared to 210.0±18.0 at peak exercise ($p<0.005$). Coronary cineangiograms obtained during CPT in 6 pts with positive exercise and CPT-Thallium 201 scintigrams did not demonstrate coronary spasm.

In conclusion, our data suggest that CPT-Thallium 201 scintigraphy is highly sensitive in detecting coronary artery disease and may be helpful in evaluating patients who are unable to perform exercise. The cause of abnormal scintigrams in patients with coronary artery disease following cold pressor test is unclear.

ACCURACY OF RADIONUCLIDE ANGIOCARDIOGRAPHY IN THE DIAGNOSIS OF CORONARY ARTERY DISEASE - A PROSPECTIVE STUDY

Erle H. Austin, M.D.; Frederick R. Cobb, M.D.; R. Edward Coleman, M.D.; Robert H. Jones, M.D., FACC, Duke University Medical Center, Durham, NC

The purpose of this investigation was to assess prospectively the accuracy of rest and exercise (R/E) radionuclide angiocardiography (RNA) in detecting coronary artery disease (CAD). By retrospective analysis of 496 patients we determined optimal RNA criteria for the presence or absence of CAD. Multivariate analysis of catheterization proven normals provided a formula to predict normal exercise ejection fraction (EF) in a given patient. The presence of CAD was indicated by one or more of the following RNA measurements: 1) rest EF <.50, 2) exercise EF .06 or more < predicted, 3) exercise increase in end-systolic volume >20 ml, 4) exercise-induced wall motion abnormality. The absence of CAD was indicated by the absence of all four criteria. These criteria were used to define a positive or negative RNA, and the diagnostic accuracy was assessed in 125 consecutive patients by comparison with coronary arteriograms. Significant CAD (>75% stenosis) was present in 70 of 86 men and in 15 of 39 women. Sensitivity (SENS), specificity (SPEC) and efficiency (EFFIC) for RNA were:

	SENS	SPEC	EFFIC
86 Men	.87	.69	.84
39 Women	.80	.50	.61
125 Patients	.86	.56	.76

We conclude that R/E RNA is sensitive and specific in men. However, poor specificity limits its value as a diagnostic tool in women.

MYOCARDIAL ISCHEMIA—EXPERIMENTAL AND CLINICAL
8:30-10:00

BRIEF REPEAT PERIODS OF ISCHEMIA HAVE A CUMULATIVE EFFECT AND MAY CAUSE MYOCARDIAL NECROSIS

Kenji Ninomiya, MD; Jun Hashida, MD; Ivor Geft, MD; Enrique Chaux; William Shell, MD; Michael C. Fishbein, MD, FACC; Jacob Rit, MD; Juliana Yano; and William Ganz, MD, FACC; Divisions of Cardiology and Pathology, Cedars-Sinai Medical Center, Los Angeles, California, 90048

Myocardial ischemia of less than 18 minute duration does not cause myocardial necrosis. The purpose of this study was to determine whether brief periods of ischemia, not causing necrosis singly, may have a cumulative effect when repeated. The proximal left anterior descending coronary artery (LAD) of closed chest dogs was repeatedly occluded by inflating and deflating the balloon of a 2F catheter for periods of either 15, 10, or 5 minutes followed by 15 minutes of reperfusion. Up to 18 cycles could be completed in a dog. For study of CPK enzyme release, blood was taken from the great cardiac vein (GCV) and the aorta before and at 2.5 and 5 minute intervals during each LAD occlusion, during and 1, 5, 10, and 15 minutes after deflation. After sacrifice, the coronary arteries were examined for patency and the myocardium for presence of necrosis by the triphenyl-tetrazolium chloride method (TTC) and by histology. In 6 out of 23 dogs with 15 minute occlusions, in 4 out of 16 dogs with 10 min occlusions and in 1 out of 4 dogs with 5 min occlusions, TTC detected small but distinct areas of necrosis in the subendocardium of the LAD area. Histology was confirmatory of or compatible with necrosis. In these dogs, there were periodical releases of enzymes into the GCV, peaking immediately following reperfusion and reflecting enzyme washout. Thus, brief repeat periods of ischemia have a cumulative effect and may produce myocardial necrosis. This finding seems relevant for the clinical setting of frequent anginal episodes.

QUANTIFICATION OF REGIONAL MYOCARDIAL BLOOD CONTENT IN NORMAL, ISCHEMIC AND REPERFUSED MYOCARDIUM

Takaya Fukuyama, MD and Robert Roberts, MD, FACC, Washington University, St. Louis, Missouri

Intramyocardial hemorrhage (HEM) and the "no-reflow" limit the potential benefits of revascularization during acute myocardial infarction and may limit the beneficial effects of reperfusion from intracoronary catheter dilatation or increased flow from calcium antagonists. To characterize HEM and assess whether it plays a role in the "no-reflow" phenomenon, a method was developed to quantify regional myocardial blood content (RMBC) based on ^{51}Cr-RBC injected I.V. (200 µCi) into dogs 30 minutes prior to sacrifice. From the concentration of ^{51}Cr-activity in myocardial biopsies (4 g) and blood, we calculated RMBC and compared it to regional blood flow (RBF) using Ce-141 microspheres in 60 animals. Flow was increased with intracoronary adenosine (n=16) and decreased by coronary occlusion (n=18). In 10 animals reperfusion was performed for 30 minutes and in 10 others for 60 minutes after 5 hr of coronary occlusion. In normals (n=6) RMBC was 3.3% of wet wt. Adenosine increased RBF 400% and RMBC by 32% (3.3 and 4.4%). In ischemic tissue RMBC decreased to 0.8% of wet wt and correlated with reduced RBF (.08 ml/min/g, r=.92). In contrast, in reperfused ischemic tissue RMBC increased 150% (8.2%) indicative of HEM but RBF decreased, being inversely related (r=-.92). Hemorrhage was consistently observed after 30 minutes but "no-reflow" only after 60 minutes, thus hemorrhage preceded the reduction in perfusion ("no-reflow"). Regional blood content can be quantified with ^{51}Cr-RBC and varies directly with flow in normal and ischemic myocardium. However, HEM varied inversely with flow in reperfused ischemic areas and preceded the reduced perfusion suggesting a causal relationship. Thus, reducing HEM may also minimize the "no-reflow" and improve perfusion in the ischemic area.

QUANTIFICATION OF MYOCARDIAL FUNCTION DURING TRANSIENT CHANGES IN REGIONAL CORONARY BLOOD FLOW

Steven R. Gundry,MD, Harry W. Siepp, Rodger E. Solomon,and Michael Jones, MD, National Heart Institute, Bethesda, Md.

The effect that transient changes in regional coronary blood flow (RCBF) have on regional and global myocardial function and the electrocardiogram is unknown. We examined the quantitative effects of controlled reductions in RCBF upon regional and global LV function and the endocardial ECG and compared these with LV function during the reactive hyperemia that followed. Paired piezo-electric ultrasound crystals were implanted in the LV free wall in the distribution of the left anterior descending coronary artery (LAD) in 7 dogs. An adjustable occluder encircled the LAD; RCBF was measured distal to this with an electromagnetic flow probe. In 42 trials (6±2/dog), regional and global LV function was measured before, during, and after reductions in RCBF of 25,50,75,90,and 100%. Reductions in RCBF at all levels tested caused significant depressions in LV function which were reversed during the period of reactive hyperemia that followed. The net changes in LV function that occurred between the ischemic period and the hyperemic period appear below:

Initial Flow Reduction	25%*	50%*	75%*	90%*	100%*
Change in RCBF post ischemia (%)	+179	+226*	+260*	+274*	+240*
Change in Cardiac Output (L/min)	0.1*	0.4*	0.7*	1.0*	0.9*
Change in Systolic Shortening (mm)	0.4*	0.7*	1.4*	1.5*	1.5*
Change in d length/dt (mm/sec)	2.0	4.6*	7.6*	8.4*	8.0*
Change LVEDP (mm/Hg)	1.4*	3.2*	6.6*	7.1*	7.1*
Change LV dp/dt (mm Hg/sec)	126	228	375	385	356
Change in Endocardial ST seg. (mm)	0	0	0	0	2

*p<0.05

These results indicate that LV function is quantitatively related to changes in RCBF. Major changes in LV function may occur in response to small changes in RCBF; these changes are not reflected in ECG abnormalities.

DEMONSTRATION OF EXERCISE-INDUCED ISCHEMIA WITHOUT ANGINA IN PATIENTS WHO RECOVER FROM OUT-OF-HOSPITAL VENTRICULAR FIBRILLATION

Bimlendra Sharma, Gary Francis, Morrison Hodges, Richard Asinger. Hennepin County Medical Center and the University of Minnesota, Minneapolis, MN.

Patients (pts) who survive OHVF may relate no warning symptoms of ischemia, although myocardial ischemia is the presumed mechanism.

Regional and global left ventricular (LV) function was assessed at rest (R) and during supine submaximal exercise (Ex) in 19 pts who recovered from OHVF. OHVF pts were divided into groups who were asymptomatic (asymp, n=11) and symptomatic (symp, n=8) for a history of angina and/or myocardial infarction. All pts had significant (≥70%) 2 or 3 vessel coronary artery disease (CAD). At catheterization no pt developed angina during Ex, but 15 of 19 pts developed ST-T depression (.113±.03 mV) and 14 of 19 pts developed abnormal wall motion indicating regional myocardial ischemia. From R to Ex the symp pts increased LV end-diastolic pressure (from 20±4 to 36±4 mmHg; $p < .005$) and volume (from 98±10 to 106±10 ml/m^2; $p < .004$) without change in ejection fraction (from 45±7 to 44±6%; pNS). Asymp pts increased LV end-diastolic pressure (from 20±2 to 31±1 mmHg; $p < .001$) and volume (from 88±4 to 92±7 ml/m^2; $p < .04$) without change in ejection fraction (from 49±4 to 43±4%; pNS indicating global LV dysfunction similar to the symp pts. This study has shown that OHVF pts with CAD have evidence of ischemia during Ex even in the absence of symptoms. This painless ischemia may have a role in the genesis of OHVF in pts with CAD.

HAEMODYNAMIC MONITORING IN PAINLESS MYOCARDIAL ISCHAEMIA.
Sergio Chierchia, MD; Mauro Lazzari, MD; Attilio Maseri, MD, FACC, University of Pisa, Italy and Royal Postgraduate Medical School, London, England.

Transient asymptomatic ST or T wave changes suggestive of ischaemia are frequently observed during ECG monitoring or anginal patients. In order to investigate whether these changes are indicative of transient myocardial ischaemia occurring without anginal pain we monitored continuously ECG, left ventricular pressure and dP/dt in 12 anginal patients showing frequent transient asymptomatic ST-T changes. All data were continuously recorded on analog magnetic tape and played back, at the end of the study, to be analysed both manually and by a dedicated computer programme. We collected a total of 278 ischaemic episodes, of which only 49 were accompanied by anginal pain. ST segment elevation occurred in 66 episodes (46 asymptomatic, 20 symptomatic), and ST depression in 85 (59,26). Of the 127 episodes with T wave changes only 3 were symptomatic. A marked decrease in LV dP/dt and increase in LV end-diastolic pressure (EDP) was consistently observed during the episodes regardless of the presence of anginal pain. The decrease in LV positive dP/dt in the symptomatic and asymptomatic episodes was 370±240 mmHg/sec (mean ± SD) and 235±200 respectively ($p<0.05$). Negative dP/dt decreased by 467±227 in the symptomatic episode and by 345±232 in the asymptomatic ones ($p<0.05$). LVEDP increased by 19 + 10 mmHg in the anginal episodes and by 12±8 in the asymptomatic ($p<0.05$). Mean duration of symptomatic and asymptomatic episodes was 646±460 sec. and 335±200 respectively ($p < 0.05$). Therefore, 1) asymptomatic episodes of ST-T changes are indicative of acute myocardial ischaemia regardless of the presence of anginal pain; 2) Anginal episodes are usually of longer duration and are accompanied by a greater impairment of LV function.

MYOCARDIAL BLOOD FLOW AT REST AND DURING EXERCISE IN DOGS WITH LEFT VENTRICULAR HYPERTROPHY
Jeffrey T. Whitmer PhD, MD; Frederick W. James MD, FACC; Samuel Kaplan MD, FACC; and M. Katherine Mackzum BS; University of Cincinnati College of Medicine, Cincinnati Ohio

Significant LV hypertrophy (H) with patent coronary arteries is thought to produce global ischemia during strenuous exercise. Transmyocardial blood flow and CI were measured at rest and during exercise in dogs with chronic H due to LV outflow tract obstruction. LVH (LV + septum weight/body weight = 6.56 ± .45 gm/kg) was induced by banding the ascending aorta in 7 puppies 3-4 months of age. Seven weight and age matched dogs served as controls (C) (LV + septum weight/body weight = 4.46 ± .24 gm/kg). Thirteen to 15 months after surgery myocardial blood flow and CI were measured at rest and during two levels of steady state treadmill exercise (1st Ex, 2nd Ex) using 15 u radioactive microspheres. Mean ± SEM heart rates (HR) in beats/min, CI in cc/min/kg, and anterior left ventricular (ALV) endocardial/epicardial flow ratios (R) in C and H dogs are as follows:

	HR		CI		ALVR	
	C	H	C	H	C	H
Rest	123±4	155±15*	169±19	135±17	1.30±.06	1.28±.07
1st Ex	216±5	244±15*	337±27	356±27	1.32±.05	1.15±.06*
2nd Ex	240±7	267±11*	407±46	410±31	1.31±.05	1.14±.07*

*p < .05 for C vs H

RVR and inferior LVR were not significantly different ($p > .05$) in C and H dogs. The relative shift of myocardial blood flow away from the ALV endocardium is suggestive of regional subendocardial ischemia rather than global ischemia during exercise. We conclude that regional subendocardial ischemia is a characteristic finding in chronic LVH due to obstruction.

SYSTEMIC LUPUS ERYTHEMATOSUS AND ISCHEMIC CORONARY ARTERY DISEASE
Richard R. Liberthson, M.D., Charles Homcy, M.D., Jay Fallon, M.D., Stephen Gross, M.D. and Lawrence Miller, M.D. Massachusetts General Hospital, Boston, MA

Seven patients (pts) with systemic lupus erythematosus (SLE) diagnosed at ages 15 to 29 years who developed ischemic coronary artery disease (CAD) were reviewed to clarify the spectrum of coronary artery abnormality in SLE. The role of serial angiography in diagnosis, the efficacy of steroid therapy in suspected coronary arteritis and various therpeutic options were assessed. Two distinct patterns of coronary abnormality were identified. Four pts (ages 20,29,29,36 yrs) had coronary arteritis diagnosed in 2 by postmortem and in 2 by serial angiography. In 1 pt dramatic alterations in coronary anatomy occurred with angiographic improvement temporally related to the initiation of high dose steroid therapy. Another patient with angiographically documented coronary artery obstruction responded to a combination of anti-anginal agents and steroids. In contrast to this pattern of isolated coronary arteritis, the remaining 2 pts also had generalized panarteritis. The second group (ages 22,23, 37 yrs) had severe diffuse atherosclerotic coronary disease which was identified in 2 at postmortem and in 1 on angiography. In the latter, coronary artery bypass grafting (CABG) relieved angina. In summary, coronary arteritis occurs in SLE and may be part of a generalized arteritic picture or limited to the heart alone. Serial angiography delineates its rapidly changing course and even total occlusion may resolve following steroid treatment. Premature accelerated coronary atherosclerosis also occurs and is closely related to steroid treatment and acquired hypertension. In some of these pts, CABG may relieve symptoms.

DIVERGENT LEFT VENTRICULAR RESPONSE TO EXERCISE IN CHILDREN WITH LEFT VENTRICULAR PRESSURE OR VOLUME OVERLOAD
J.A. Breitweser, M.D., R.C.Boerth, M.D., T.P.Graham,Jr., M.D.,FACC, J.T. Weinberger, D.J. Petty, Division of Pediatric Cardiology, Vanderbilt Medical Center, Nashville TN 37232

Although exercise (EX) induced left ventricular (LV) dysfunction has been observed in adults with aortic regurgitation (AR), in children, this and the LV response to EX in patients with aortic stenosis (AS) have not been clearly characterized. To better determine these responses, we performed supine bicycle EX on 6 patients (pt) with AS (11.3±1.4 years): 3 moderate valvar, 2 moderate supravalvar, and 1 mild subvalvar, and 5 pt with AR (11.3±2.2 years): 5 moderate and 1 severe with mild mitral insufficiency. Their heart rates (HR), total work capactities (TWC), and echographic LV end-diastolic dimension (LVED) and shortening fractions (SF) were compared to results in 11 normal children (nl)(11±1 years). Pt with AS had TWC and HR increase of 3380±610 KPM/M^2 and 80±7 BPM ($\bar{x}$ ±SEM) respectively which were virtually the same as nl (3843± 749 KPM/M^2 and 88±10 BPM). The TWC and ΔHR of pt with AR were insignificantly lower than nl (2560±870 KPM/M^2, 58± 10 BPM), but EX was stopped in 1 pt because of a systolic BP > 230 mm Hg. Resting LVED of pt with AR(58±6.2 mm)was significantly($p < 0.01$)larger than that of nl (42±2.1 mm) or AS(39±1.4mm). All LVED decreased with EX. At rest, SF of pt with AS(42±2%) was not significantly larger than that of nl (39±2%), nor was the SF of pt with AR(34±3%) significantly less than nl. However, at maximal EX, pt with AS had SF of 53±3% which was significantly greater ($p < 0.05$) than that of nl (46±1%). In contrast, pt with AR had SF of 33±3% which was significantly lower than nl ($p < 0.01$). These findings confirm the EX induced LV dysfunction in children with AR, and suggest a hypercontractile LV response to EX in children with AS.

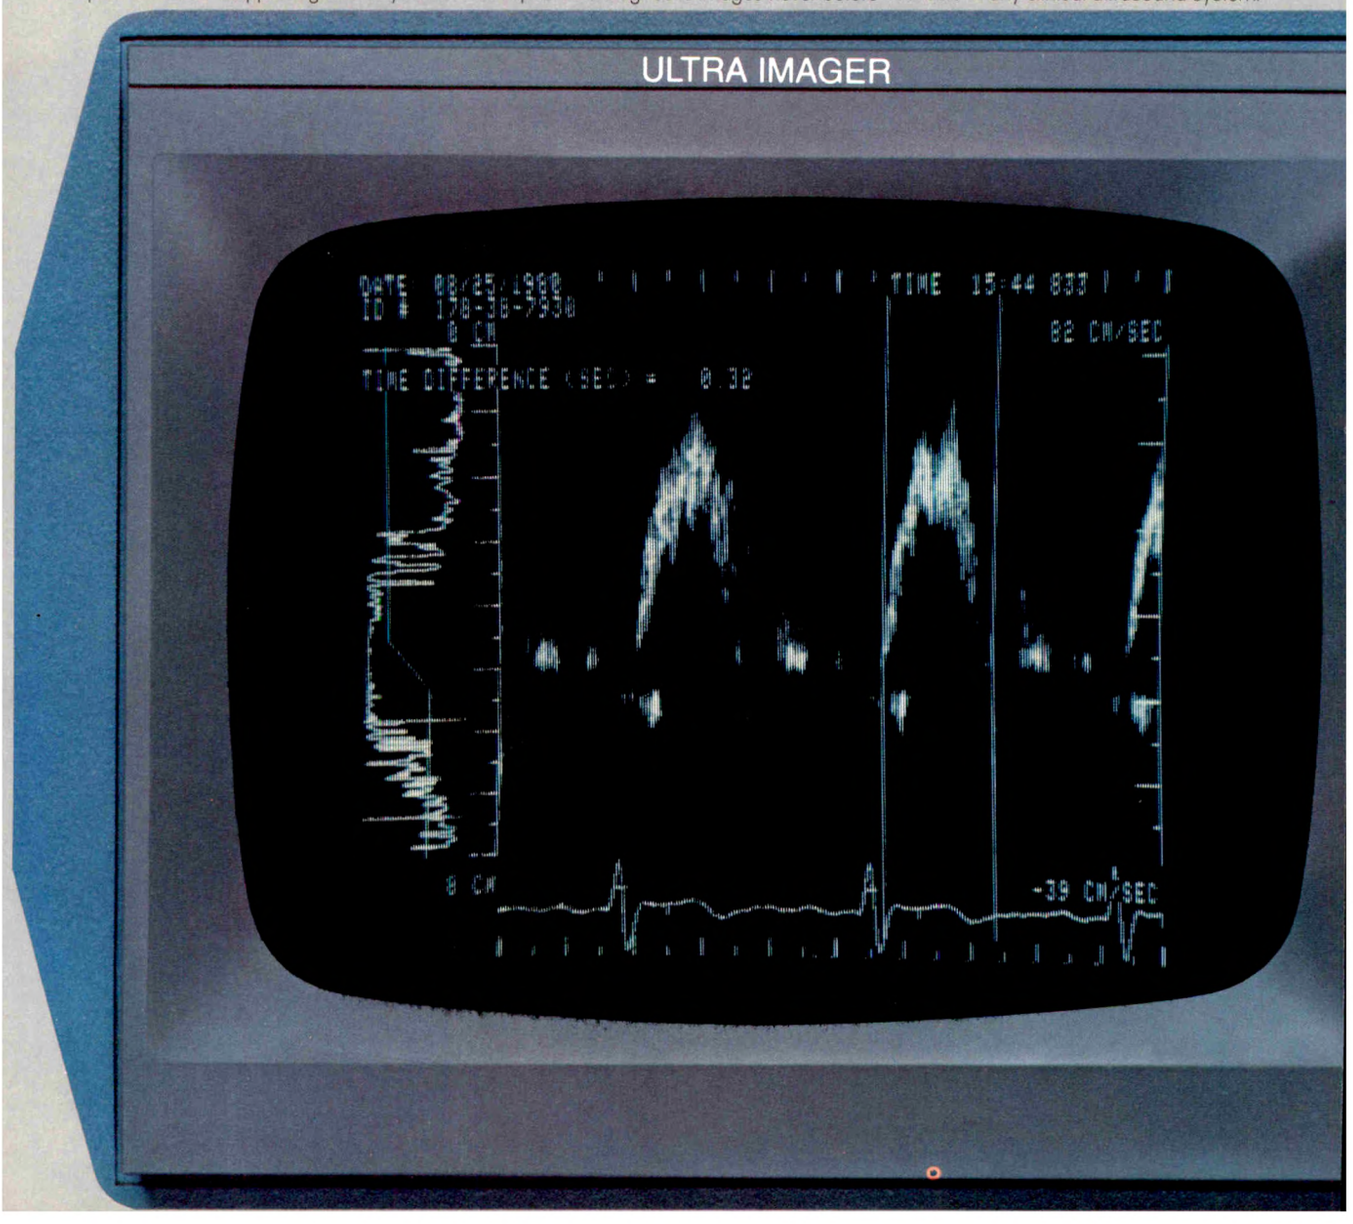
E for M/Honeywell announces the first major advance of the 1980's in echocardiography...

Ultra Imager

The only integrated digital echocardiography system with all three major modalities for complete ultrasound diagnosis:

- **FFT Doppler**
- **2D Real-time**
- **M-mode**

This pulsed Doppler display is a precise, quantitative representation of a spectrum of blood velocities in the pulmonary artery. The Ultra Imager's unique method of Doppler signal analysis ensures repeatable diagnostic images never before available in any clinical ultrasound system.



MORPHOLOGICAL-CLINICAL CORRELATES OF MYOCARDIAL FIBROSIS DUE TO DISCRETE SUBAORTIC STENOSIS IN NEWFOUNDLAND DOGS

Michael Jones, M.D.; Victor J. Ferrans, M.D.; William C. Roberts, M.D., FACC; A. Michael Borkon, M.D.; Joseph E. Pierce, D.V.M., National Heart Institute, Bethesda, Md.

We investigated the clinical and morphological interrelationships of myocardial fibrosis in infracoronary LV obstruction (LVOTO) due to discrete fibrous subaortic stenosis in Newfoundland dogs. Group I (n = 16) had no LVOTO, aged 4 to 61 months (mean 28 months), had LV/body weights of 3.3 ± 0.6 g/kg, had minimal interstitial fibrosis, and normal intramural coronary arteries. Group II (n = 12) had LVOT gradients of 50 - 95 mm Hg, aged 12 - 78 months (mean 27 months), and had LV/body weights of 6.4 ± 0.5 g/kg. In these dogs with LVOTO the LV mural and septal myocardium had replacement fibrosis, prominent perivascular fibrosis, and intramural coronary arteries with fibromuscular intimal hyperplasia. Group III (n = 16) suffered sudden death, aged 4 - 65 months (mean 27 months), had morphologic evidence of LVOTO, and LV/body weights of 5.7 ± 0.7 g/kg. Besides prominent interstitial fibrosis, these dogs had marked replacement fibrosis, recent myocardial necrosis, and intramural coronary arteries with fibromuscular hyperplasia in the septum and LV free wall. Extramural coronary arteries in all dogs were normal. Total LV blood flow, determined by radioactive microspheres, was not significantly different in 6 dogs with and 6 dogs without LVOTO (0.70 ± 0.09 versus 0.76 ± 0.14 ml/g/min); however, endocardial/epicardial flows for dogs with no LVOTO were 1.10 ± 0.09 versus 0.86 ± 0.04 for dogs with LVOTO ($p < 0.05$). Thus, our observations in this animal model of human infracoronary aortic stenosis indicate that LVOTO progresses to LV hypertrophy, intramural coronary arterial obstruction, myocardial fibrosis, and sudden death.

MORPHOMETRIC ANALYSIS OF LUNG BIOPSY TISSUE IN CANDIDATES FOR FONTAN-TYPE SURGICAL PROCEDURES

Marlene Rabinovitch, M.D.; Stephen P. Sanders, M.D.; Aldo R. Castaneda, M.D., FACC; and Lynne Reid, M.D., Children's Hospital Medical Center, Boston, MA

Lung biopsy tissue was obtained at cardiac surgery from 21 patients with either tricuspid atresia (TA) or single ventricle (SV) and analyzed, using morphometric techniques, to determine (a) whether pulmonary vascular changes were present which might result postoperatively in elevated resistance (Rp) and (b) the conditions under which these changes were likely to occur. In 10/13 TA patients, only abnormal extension of muscle into peripheral arteries (Grade A), was observed; 9/10 have undergone Fontan-type surgical procedures (FP), all with excellent hemodynamic results, in spite of preoperative mean pulmonary artery pressure ($\bar{P}_{Pa}$) values as high as 28 mmHg. The remaining 3/13 patients had impaired growth of the peripheral arteries (Grade C) and Heath Edwards ≥Grade III changes in at least one lung. All had had large Waterston shunts of >5 years' duration. Only 1/3 patients had an FP and he died in congestive heart failure. Three of 8 SV patients had only Grade A changes; all underwent FP but 2/3 died largely due to technical difficulties at surgery. The remaining 5/8 patients had, (in spite of preoperative $\bar{P}_{Pa}$ values as low as 10 mmHg), Grade C changes with eccentric intimal hyperplasia and recanalized thrombi in the intra-acinar arteries of at least one lung. All had had tight PA bands or inadequate shunts; 2 had severe polycythemia (hematocrit >70%). Both patients with FP died; no technical difficulties were identified. We conclude that severe pulmonary vascular changes may occur in TA or SV patients with either excessive or inadequate pulmonary blood flow; they may not be predicted from preoperative hemodynamics but may result in postoperative elevation in Rp, precluding a favorable result from a Fontan-type procedure.

RECIPROCAL DEVELOPMENT OF 4TH AND 6TH AORTIC ARCHES IN PULMONARY ATRESIA WITH VENTRICULAR SEPTAL DEFECT

Gaetano Thiene M.D., Carla Frescura M.D., Uberto Bortolotti M.D., Alessandro Del Maschio M.D., Marialuisa Valente M.D., University of Padova, Italy

25 specimens of pulmonary atresia with ventricular septal defect (PAVSD) have been studied by gross examination, microangiography and histology in order to establish whether a relationship exists between the extreme obstruction of the right ventricular outflow, the development of the aortic arch (AA) system and pulmonary arterial supply. The results of our study indicate that: 1) when ductus arteriosus (DA) is absent the lungs are entirely supplied by systemic collateral arteries (SCA); 2) DA and SCA do not coexist in supplying the same lung; 3) the peripheral pulmonary vessels function for gas exchange regardless the source of blood supply. In the normal development of the arterial pole of the heart, only the 4th and 6th AAs persist to join 2 separated ventricular bloodstreams to the descending aorta; the pulmonary arterial plexus develops in situ connecting first with the descending aorta through SCA and then to the pulmonary trunk through the 6th AA. In PAVSD both ventricular outputs are forced into the 4th arch; this is likely to explain the partial or complete involution of the 6th arch accounting for the cases with absent DA and for those with absent DA and pulmonary arteries. Accordingly the pulmonary arterial circulation maintains its primitive source of blood supply through SCA.

MORPHOLOGIC FEATURES OF THE DUCTUS ARTERIOSUS AFTER PGE_1 ADMINISTRATION FOR DUCTUS DEPENDENT CONGENITAL HEART DISEASES

InSook Park, MD, Michael R. Nihill, MD, FACC, Jack L. Titus, MD, The Lillie Frank Abercrombie Section of Pediatric Cardiology, Department of Pediatrics and the Department of Pathology, Baylor College of Medicine, and Texas Children's Hospital, Houston, Texas.

Histologic evidence of damage to the ductus arteriosus (DA) has been reported in neonates with ductus dependent congenital heart defects (CHD) after the use of Prostaglandin E_1 (PGE_1); the reported changes suggested structural weakening of the DA that might render it prone to laceration or rupture. We studied the morphology and histology of the DA in two groups of neonates with ductus dependent CHD. Group I was 12 neonates who received PGE_1 and died within 4 days after PGE_1 were discontinued. Mean duration of PGE_1 administration was 17 hrs (range from 30 minutes to 40 hours). Group II was 8 neonates who did not receive PGE_1 and were matched with group I for age, weight, type of CHD, and age at death. The gross morphology and histology of the DA were examined without knowledge of the clinical history. The length and internal diameter of DA were greater in PGE_1 group than control group ($P<0.15$). Histological staging of maturation (stage 1 being most immature; stage 4 being most mature or closing) showed that group I DA were significantly less mature than group II (mean stage 1.64 ± 0.32 vs 2.94 ± 0.33 $P<0.005$). Pathological findings reported in the previous study were not found in either group. We conclude that PGE_1 administration may delay the normal closing process or maturation of the DA but does not have any significant deleterious effect morphologically. Clinical follow up of 54 survivors up to 33 months after PGE_1 treatment suggest that the ductus closes normally after PGE_1 is discontinued with no deleterious sequele.

VENTRICULAR ARRHYTHMIAS I: ASSESSMENT OF SUSCEPTIBILITY
8:30-10:00

ANATOMIC AND ELECTROPHYSIOLOGIC CORRELATES OF VENTRICULAR TACHYCARDIA REQUIRING LEFT VENTRICULAR STIMULATION
Michael E. Cain, MD; James F. Robertson, MD; Leonard N. Horowitz, MD, FACC; John A. Kastor, MD, FACC; Mark E. Josephson, MD, FACC, Hospital of the University of Pennsylvania, Philadelphia, Pa.

Therapy of ventricular tachycardia (VT) based on results of programmed ventricular stimulation (PVS) requires reproducible initiation of VT. With a ventricular stimulation protocol of single and double extrastimuli at 3 cycle lengths and bursts of rapid pacing to cycle lengths of 250 msec, 12 of 108 patients (11%) with reproducible initiation of VT required LV-PVS for initiation. The clinical, ECG, anatomic and electrophysiologic features of the 96 patients induced by RV-PVS (Group A) were compared to the 12 patients (Group B) in whom VT was only induced by LV-PVS. There were no significant differences between Groups A and B in incidence of coronary artery disease (81% vs 100%), anterior (59% vs 73%) or inferior (54% vs 45%) myocardial infarction, presence of aneurysm (67% vs 50%) or mean LV end diastolic pressure (17±9 vs 12±6 mm/Hg). Comparison of electrophysiologic parameters revealed no significant differences in mean A-H intervals (92±22 vs 89±15 msec), H-V intervals (59±15 vs 59±15 msec), RV effective refractory periods (RV-ERP 241±38 vs 260±40 msec) and LV-ERP (232±28 vs 251±43 msec) between Groups A and B respectively. VT with right bundle branch block and superior axis was more frequent in Group B (91% vs 32%, $p<.001$) but was also observed in 32 patients in Group A. We conclude that 11% of patients will require LV-PVS to initiate VT. No clinical, anatomic, ECG or electrophysiologic features predict whether LV-PVS will be required. Since VT initiation by PVS has important prognostic and therapeutic implications, LV-PVS should be performed when VT is not initiated by RV-PVS.

SIGNIFICANCE OF REPETITIVE VENTRICULAR RESPONSES INDUCED BY ATRIAL AND VENTRICULAR PACING IN PATIENTS WITH AND WITHOUT VENTRICULAR TACHYCARDIA.
Gerald V. Naccarelli, MD; Eric N. Prystowsky, MD, FACC; Warren M. Jackman, MD; Robert L. Rinkenberger, MD; James J. Heger, MD; Douglas P. Zipes, MD, FACC, Krannert Institute of Cardiology, Indiana University School of Medicine, Indianapolis, Indiana.

The purpose of this study was to determine: 1) the prevalence of repetitive ventricular responses due to non-bundle branch reentry (nBBR) and bundle branch reentry (BBR) induced by a single ventricular stimulus during atrial (AP) and/or ventricular pacing (VP) in pts with and without ventricular tachycardia (VT); and 2) the prognostic significance of nBBR in VT and non-VT pts. The prevalence during a drug free control state was:

	VT Patients(N=47)		NON-VT Patients(N=50)	
	VP(N=47)	AP(N=27)	VP(N=50)	AP(N=21)
nBBR	33(70.2%)	9(33.3%)	15(30.0%)	1(4.8%)
BBR	22(46.8%)	1(3.7%)	28(56.0%)	2(9.5%)

To determine if nBBR predicted future symptomatic VT or sudden death (SD), 59 VT pts had a discharge study and were followed for a mean of 10.3 months.

VP(N=59)	AP(N=33)
35 nBBR+ → 11 VT, 6 SD	11 nBBR+ → 6 VT, 2 SD
24 nBBR- → 5 VT, 1 SD	22 nBBR- → 7 VT, 2 SD

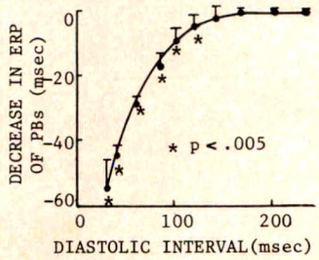
In the non-VT group no pt had a symptomatic event although 30.0% had nBBR induced during VP. In 16 VT pts who had VT induced on discharge study, 8 pts had nBBR on AP and 8 did not. Spontaneous VT/SD occurred in 7/8 (87%) who had nBBR on AP, but only in 2/8 (25%) who did not ($p<.05$). Conclusions: 1) in pts with VT, the induction of nBBR during VP is more sensitive, during AP more specific; however, neither technique alone is adequately predictive; 2) induced VT associated with nBBR on AP may define a high risk group.

REFRACTORINESS OF PREMATURE AND NONPREMATURE BEATS IN THE HUMAN VENTRICLE.
James R. Foster, MD, FACC, Ross J. Simpson, Jr., MD, and Leonard S. Gettes, MD, FACC, University of North Carolina, Chapel Hill, NC

Despite the critical role of premature beats(PBs) in initiating ventricular arrhythmias, much less is known about electrophysiology of PBs than about nonpremature beats(NPBs). On the basis of previous single fiber studies we hypothesized that refractoriness(R) of PBs having long coupling intervals(CIs) differs little from R of NPBs, but that R of early PBs shortens progressively as CI decreases.

We tested this hypothesis in two ways. First, we defined strength-interval(SI) curves of NPBs and of PBs having several CIs during electrophysiologic study in 12 patients (pts). As compared to SI curves of NPBs and late PBs, SI curves of early PBs were shifted significantly ($p < .005$) leftward toward shorter CIs.

Second, we measured the effective refractory period (ERP, shortest CI producing a response at 10mA) of PBs at multiple (6-10) diastolic intervals(DIs) in 6 pts. [The DI is a way of normalizing the coupling interval to the ERP of the NPB(ERP-NPB) and equals CI minus ERP-NPB] The figure plots the relationship between DI and the mean ±SD decrease (from ERP-NPB) in the ERP of PBs. The figure shows that R of PBs decreases little at long DIs, but decreases rapidly as DI approaches ERP-NPB.



Conclusions: 1) refractoriness of early PBs is much shorter than that of late PBs; 2) since early PBs may conduct very slowly, this marked shortening of their refractoriness may be an important determinant in the genesis of re-entrant ventricular tachyarrhythmias.

FRAGMENTED ELECTRICAL ACTIVITY-RELATIONSHIP TO VENTRICULAR TACHYCARDIA
Scott R. Spielman, MD; William J. Untereker, MD,FACC; Leonard N. Horowitz, MD,FACC; Allan M. Greenspan, MD,FACC; Michael B. Simson, MD,FACC; John A. Kastor, MD,FACC; Mark E. Josephson, MD,FACC. Hospital of the University of Pennsylvania, Philadelphia, Pa.

Endocardial activation mapping was performed in normal sinus rhythm at 12 left ventricular (LV) sites in each of 17 patients (pts) - Group I: 5 pts without myocardial infarction (MI); Group II: 5 pts with prior MI but without arrhythmias; and Group III: 7 pts with MI and recurrent sustained ventricular tachycardia (RSVT). In Group I pts discrete electrograms were recorded at all sites while in 3/5 Group II pts and 7/7 Group III pts fragmented electrograms (high frequency, low amplitude {1mV}, prolonged {>50 msec} potentials with no discrete intrinsicoid deflections) were consistently recorded within infarcted zones. Zero-5 (m=2.4±2.4) electrograms were fragmented in Group II pts compared to 4-9 (m=5.6±2.2) electrograms in Group III pts ($p<.05$). The duration of the most fragmented electrograms ranged from 75-90 msec (m=78±2.7) for Group II pts and 95-170 msec (m=131.4±28.7) for Group III pts ($p<.01$). The total duration of LV endocardial activation was 32-53 msec (m=41.6±9.6) for Group I pts, 23-95 msec (m=67±33) for Group II pts, and 95-200 msec (m=150±38.4) for Group III pts. We conclude that fragmented electrical activity: 1) is common in infarcted zones, 2) is longer in duration and more extensive in pts with RSVT and 3) may be due to slow conduction, a substrate for reentrant arrhythmias.

REPRODUCIBILITY OF ELECTROPHYSIOLOGIC RESPONSES TO PROGRAMMED VENTRICULAR STIMULATION DURING SERIAL DRUG TESTING IN PATIENTS WITH RECURRENT VENTRICULAR TACHYCARDIA

Jeremy N. Ruskin, MD, FACC, John P. DiMarco, MD, Hasan Garan, MD, Cardiac Unit, Massachusetts General Hospital, Boston, Mass.

The reproducibility of electrophysiologic responses to programmed ventricular stimulation (PVS) was examined in 22 consecutive patients with recurrent ventricular tachycardia (VT) in whom PVS-inducible VT was fully suppressed by at least one antiarrhythmic drug (AAD) regimen. PVS consisted of 1 and 2 premature right ventricular stimuli delivered during sinus rhythm, atrial pacing, and right ventricular apical pacing, as well as brief (3-5 beat) bursts of rapid ventricular pacing at 150-280 beats per minute. VT was initiated reproducibly by PVS off AAD in all patients and was sustained in 14 patients and nonsustained in 8 patients. During serial AAD testing, VT was initiated by PVS an average of 4 times (range 1-10), each on separate days, in all 22 patients. In all 22 patients, complete suppression of PVS-inducible VT was achieved with an AAD regimen. Repeat PVS on the same AAD regimen was carried out 1 to 4 days later in all patients. Patients were retested randomly with regard to the time of their last AAD dose. In 21 of 22 patients (95%), repeat PVS revealed persistent noninducibility of VT; whereas, in 1 patient VT was inducible during repeat testing on the same AAD regimen. These observations demonstrate that the complete suppression of PVS-inducible VT by an AAD regimen is a highly reproducible finding when PVS is repeated at 1 to 4 days.

CORONARY ARTERY SPASM
8:30-10:00

HOW USEFUL IS THE ELECTROCARDIOGRAM AS AN INDICATOR OF CORONARY ARTERY SPASM?

Robert L. Feldman, MD; James Hill, MD; Carl J. Pepine, MD, FACC; C. Richard Conti, MD, FACC, Univ. of Florida and VA Medical Center, Gainesville, FL.

Transient changes of the electrocardiogram (ECG), usually manifest as significant ST shifts ($\geq$ 1mm), occurring during rest angina are sought as evidence for myocardial ischemia. Frequently, in patients with rest angina, the basis for transient myocardial ischemia has been shown to be coronary artery (CA) spasm (S). During catheterization performed to further evaluate the basis for angina, we found 7 patients who had rest angina accompanied by CAS (transient 100% obstruction of a major coronary artery in 4 patients or diffuse >50% diameter narrowing in 3 patients). During the episode of rest angina associated with CAS, none (0 of 7) of these patients had significant ST shifts in standard limb (I-AVF) and selected precordial ECG leads compared to ECGs recorded during pain-free intervals occurring immediately before or after relief of angina and reversal of CAS. At other times, each patient also had at least five 12 lead ECGs recorded during rest angina and at least two 24 hour dual-lead ambulatory monitor ECG recordings on days when they had angina. Again, no significant ST shifts were found during rest angina in 3 patients. In the other four patients ST shifts were found during <20% of the rest pain episodes observed.

These findings suggest that the ECG has important limitations as an indicator of myocardial ischemia associated with CAS in selected patients with rest angina. The absence of significant ST shifts during rest pain does not necessarily exclude CAS.

CONTRASTING EFFECTS OF PROCAINAMIDE AND VERAPAMIL ON INTRAVENTRICULAR CONDUCTION AND REENTRY

C. Pratap Reddy, MD, FACC; Borys Surawicz, MD; Russell G. McAllister, MD, FACC, Veterans Administration and University of Kentucky Medical Centers, Lexington, KY

The effect of intravenous Procainamide (PA) (8-14 mg/kg) and Verapamil (V) (0.075-0.15 mg/kg) on intraventricular conduction and reentry (Re) within the His-Purkinje System (HPS) were studied in 23 patients (pts) utilizing His (H) bundle electrograms and ventricular extrastimulus method. PA was studied in 13 pts and V in 10 pts. Data (in msec) for both groups are shown below.

	PA	V
Zone of Re	68±18 vs 33± 8*	60±20 vs 56±22+
Critical V_2H_2	214±27 vs 286±13*	194±15 vs 196±14+
Longest V_2H_2	253±26 vs 299±38*	254±19 vs 253±19+
QRS duration of V	128± 5 vs 136± 6*	129± 3 vs 139± 3+
Latency	15± 5 vs 21± 6*	18± 4 vs 130± 3+
	*<0.005	+>0.1

V produced significant prolongation of atrioventricular nodal (AVN) conduction (A-H interval: 91±12 vs 98±16; $p<0.05$) and refractoriness (functional refractory period of AVN: 396±44 vs 448±53; $p<0.001$) in all pts. CONCLUSIONS: 1) Whereas PA [plasma concentration (PC) 12±5 mg/L] significantly prolonged the duration of latency and intramyocardial (IM) and HPS conduction and narrowed the zone of Re, V in therapeutic PC (138±27 ng/ml) which caused significant prolongation of AVN conduction and refractoriness did not change the duration of latency and IM and HPS conduction and the zone of Re. 2) Slow channel dependent conduction plays no detectable role in propagation of even the earliest premature impulses delivered before the completion of repolarization of HPS and/or ventricular muscle.

EXPERIMENTAL CORONARY ARTERY SPASM IN INTACT DOG: ANGIOGRAPHIC CHARACTERIZATION, RECORDING OF FLOW, AND RESPONSE TO DIHYDROPYRIDINES

Julio E. Pérez, MD; Cynthia Lucas, BS; Philip D. Henry, MD, FACC, Washington University, St. Louis, MO.

An animal model for the study of coronary spasm was developed. Attempts to induce non-thrombotic, segmental spasms by infusing constrictors into major coronary arteries (8 dogs) or by electrically stimulating the vessels with ring electrodes (4-16 Hz; 9 dogs) were unsucessful. Therefore, effects of direct application of drug to the surface of the vessels were evaluated. Three cm long segments of the left anterior descending coronary artery of open-chest dogs (n=9) were covered with ion exchange gels containing adsorbed ions or drugs. Coronary flow was monitored with a proximal electromagnetic flow probe. SP-Sephadex in the K^+-cycle decreased flow by 38 ± 7% (SE; $p < .01$), whereas the same gel in the Na^+-cycle had no effect. K^+-induced spasms were relieved by removal of the gel, and the spasms were reproducible on repeated applications. Ventricular pressure, dP/dt, and heart rate remained unchanged. Peak reactive hyperemia after complete occlusion for 15 sec was decreased by 68 ± 7% compared to the response before spasm ($p < .001$). Selective coronary arteriography during spasm revealed the internal diameter of the treated segment to be reduced by 21 ± 6% ($p < .01$). Equihypotensive doses of nitroglycerin (50 µg/min, i.v.), nifedipine (1 µg/min, i.v.), and BAY k 5552 (.2 µg/min, i.v.) increased flow during spasm by 33 ± 4%, 95 ± 8%, and 186 ± 18%, respectively. Nitroglycerin produced partial, and the dihydropyridines complete relief of the spasms on angiography. Thus, reversible segmental spasms were documented by arteriography, and the new dihydropyridine derivative BAY k 5552 was shown to be a very potent spasmolytic agent.

ORONARY VASOSPASM PROVOKED BY THE HYPERVENTILATION TEST. uillermo Pujadas, MD, FACC; Alberto Tamashiro, MD; José uades, MD; José Aldasoro, MD. Laboratorio de Hemodinámica ospital Italiano de Buenos Aires, Argentina.

he purpose of this paper was to investigate with which requency alkalosis provoked by hyperventilation performed uring 5 minutes (HV) induces coronary artery spasm (CAS) n patients with angina pain. Method: The patient hyperentilates while the ECG is continuously monitored (L_2-V_5) until: 1)ST segment elevation≥1mm. or seudo-normalzation of an inverted T wave occurs; 2)ST segment depresion≥2mm. appears; 3)the 5 minutes of HV as well as 15 miutes of follow-up elapsed and no repolarization changes ppeared or if there were changes they did not follow the wo previous patterns. A coronary angiogram was performed efore, inmediately after the HV and 5 minutes after ,6 mg. of nitroglycerine administered sublingually. The ngiographic findings were reported as: 1)Localized spasm LS); 2)Diffuse narrowing (DN) -mild when it reduced the rteries diameter between 20 and 50%; severe>50%-. esults: The HV test was performed in 59 patients, CAS ocured in 17 (29%): 13 patients with LS, 2 with severe DN, nd 2 with mild DN. Results according to the clinical ubset: In atypical angina 15% (4/27) had CAS (1 LS, 1 sere DN, and 2 mild DN). In Prinzmetal's angina (angiographically normal arteries) the 2 patients had LS. Only of the 10 patients with stable angina had CAS (mild LS), ut in unstable angina 67% (6/9) had CAS (5 LS and 1 sere DN). In the subset of slowly progressive angina -angina that worsens slowly in weeks or months- 36% (4/11) of atients had CAS, all LS. The CAS was easily relieved by itroglycerine in all patients. Conclusions: Coronary ngiography demostrates that the hyperventilation test rovokes vasospasm with similar frequency than the one reorted in the literature for the ergonovine test. Coronary pasm appears more frequently in unstable angina.

EFFECTS OF COLD-PRESSOR TEST ON REGIONAL CORONARY HEMODYNAMIC AND ANGIOGRAPHIC RESPONSES. Robert L. Feldman, MD, James L. Whittle, M.D., Carl J. Pepine, MD, FACC, C. Richard Conti, MD, FACC, Univ. of Florida and VA Medical Center, Gainesville, Florida.

To more clearly define the effects of the cold pressor test (CPT) on the coronary circulation, coronary sinus (CSF) and great cardiac vein (GCVF) flows (F), aortic (Ao) and left ventricular (LV) pressures (P) and epicardial and small (0.3±1.0 mm) intramyocardial coronary artery (CA) diameters were measured in 12 patients. Determinations were made before and after CPT. CSF and GCVF were used as indices of total and anterior LVF and CSF-GCVF as an index of inferior F. Perfusion of LV regions was considered potentially "normal" (nl) or "abnormal" (abn) based on the presence or absence of ≥50% narrowing in the CA supplying a given region. Perfusion was potentially "nl" in 14 and "abn" in 10 regions. With CPT, heart rate (5 beats/min), mean AoP (23 mmHg) and LV-end-diastolic P LVEDP (6 mmHg) increased, all $p<0.05$. "Nl" region LVF increased (72±46 to 94±50 ml/min, mean ±SD) as resistance (CR) decreased (2.63±2.78 to 2.31±2.43 mmHg/ml/min), both $p<0.05$. "Abn" region LVF was unchanged (55±22 to 53±15 ml/min, p=NS) and CR increased (2.15±0.84 to 2.63±0.77 mmHg/ml/min, $p<0.05$). CA diameter decreased only minimally in both "nl" (6±9%) and "abn" (8 11%) regions, both $p<0.05$. Furthermore, both "nl" and "abn" region angiographic responses were similar (p=NS). These data show that CPT increases CR in angiographically defined potentially "abn" regions. These increases in CR are not due to CA "spasm" but may be due to a differential effect of an increased LVEDP on regional blood flow.

LINICAL USE OF ALCALOSIS AS A PROVOCATIVE TEST OF CORONARY SPASM.
imon Weber MD, Alain Guiomard MD, Bernard Lancelin MD, lorent de Vernejoul MD, René Gourgon MD, Michel egeorges MD. University René Descartes School of Medecie, Paris, France.

Alcalosis (ALC) was used as a provocative test of coronary spasm in 70 patients (pts) (mean age 56) with angina t rest. Rapid infusion of 200 ml. Tris Buffer immediately followed by 5 minutes of maximal hyperventilation raied arterial pH to 7.67 ± 0.05. ALC induced chest pain nd ischemic ECG changes in 24 pts : ST elevation in 10 ts and ST depression in 14. Ischemic changes occurred du ing hyperventilation in 16 pts and within 3 minutes afer its discontinuation in 8. During hyperventilation eart rate increased from 66 ± 11 to 71 ± 14 ($p<0.01$) ut systolic arterial pressure decreased from 139 ± 12 mHg to 130 ± 12 mmHg ($p<0.01$) and thus the rate-pressue product did not change. (9130 ± 1750 versus 990 ± 2690. NS.). In all cases pain and ECG changes reressed within a minute, after 1 mg intravenous nitroglyerin. Coronary arteriography documented significant ≥70 %) stenosis in 21 pts ; 3 pts had normal angiograms ut 0.4 mg of methylergometrine induced coronary and ECG hanges similar to ALC.

ALC was repeated in 16 of the 24 positive responders ne hour after oral administration of 20 mg of the calium antagonist Nifedipine and was then constantly negative. We conclude that ALC can be used in a coronary care nit as a provocative test of coronary spasm. Response to LC may contribute to determine the mechanism of angina t rest, to choose the optimal medical therapy and to ass its efficiency.

CORONARY ARTERY SPASM: AN ISOLATED PHENOMENON OR ONE MANIFESTATION OF A MORE DIFFUSE VASCULAR HYPERREACTIVITY? Joaquin Arciniegas, MD; William C. Little, MD; H. Cecil Coghlan, MD; Richard O. Russell, Jr., MD, FACC; Charles E. Rackley, MD, FACC; John A. Mantle, MD, FACC. Division of Cardiology, University of Alabama in Birmingham, Birmingham, Alabama.

To investigate a possible association of coronary artery spasm with other vasospastic disorders, the frequency of vascular headaches and Raynaud's phenomenon was determined in 43 patients with chest pain who were evaluated for the presence of coronary artery spasm. Eighteen patients (Group I) had coronary artery spasm documented by ST abnormalities during spontaneous chest pain or with ergonovine stimulation tests. Twenty-five patients (Group II) had no evidence of coronary artery spasm despite ergonovine stimulation. Group I and II were similar in mean age (54 vs 48 yrs), sex ratio (10 males, 8 females vs 14 males, 11 females), and presence of greater than 50% luminal diameter coronary artery stenosis (38% (7/18) vs 36% (9/25)). Vascular headaches or Raynaud's phenomenon was present in 39% (7/18) in Group I and 8% (2/25) in Group II ($p<.025$). Vascular headaches occurred in 16% (3/18) of Group I and 4% (1/25) of Group II (p=NS). Raynaud's phenomenon was present in 38% (5/13) of Group I and 4% (1/25) of Group II ($p<.05$). All four of the patients with Raynaud's phenomenon who received nifedipine for coronary artery spasm noted relief of Raynaud's phenomenon concomitant with relief of chest pain. The strong association between coronary artery spasm and other disorders with increased vascular reactivity suggests a common etiology.

In summary: 1) Disorders characterized by increased vascular reactivity frequently coexist with coronary artery spasm; 2) Nifedipine was useful in controlling Raynaud's phenomenon as well as chest pain in these patients.

ADULT CARDIOLOGY/CLINICAL STUDIES
8:30-10:00

COMPUTED TOMOGRAPHY. A USEFUL TECHNIQUE FOR FOLLOW-UP OF BOTH MEDICALLY AND SURGICALLY TREATED PATIENTS WITH THORACIC AORTIC DISSECTION. Martin Lipton, MD; Kevin Turley, MD, FACC; J. David Godwin, MD; Erik Carlsson, MD; Paul A. Ebert, MD, FACC; John C. Hutchinson, MD, FACC, University of California, San Francisco, CA 94143.

Dissection of the thoracic aorta represents the most common catastrophic event involving the great arteries. Improvements in both surgical management and the use of antihypertensive therapy have improved early survival. However, persistence of the false lumen has been demonstrated in a high percentage of the surgically treated patients (85%) and the reentry point remains in those medically managed. Thus, the persistent risk in both medically and surgically treated patients of expansion and redissection must be monitored. Computed tomography uses the technique of CAT scanning at multiple levels of the thoracic and abdominal aorta coupled with contrast injection to demonstrate both true and false lumen perfusion at each level, and then special computer programs to reconstruct the thoracic and abdominal aorta in the longitudinal plane. Grafts, intimal flaps, and false lumen perfusion are clearly delineated. 16 patients, 11 with surgically treated thoracic-aortic dissections, and 5 patients with medically treated dissections (i.e. antihypertensive therapy) have been evaluated using this modality. The studies demonstrate persistence of the false lumen in 11 patients, with definition of aortic intimal and adventitial size in both these patients and in those with clotted false lumens. This technique affords a reproducible profile of the anatomy of the involved areas, both in the transverse plane of the CAT scan at specific levels, and reconstruction in the longitudinal plane of the thoracic and abdominal aorta, thus avoiding the need for repeated arteriograms for follow-up of aortic size and false lumen.

REVERSIBLE SEGMENTAL CONTRACTION ABNORMALITIES DURING EXERCISE INDUCED CORONARY ARTERY SPASM AND THEIR EFFECT ON GLOBAL LEFT VENTRICULAR FUNCTION.
Robert A. Chahine, MD, FACC; Mario S. Verani, MD, FACC; Nadim M. Zacca, MD, FACC; Albert E. Raizner, MD, FACC; Felix Pircher, MD; Richard R. Miller, MD, FACC; Robert J. Luchi, MD, FACC, Baylor College of Medicine and VAMC, Houston, Texas.

Very few observations have been published concerning the effect of coronary artery spasm (CAS) on left ventricular (LV) contraction. Accordingly, 4 patients (pts) with angiographically documented recurrent exercise (EX) induced CAS resulting in transient total or near total occlusion of a major vessel underwent gated radionuclide ventriculograms (RNVG) at rest (RT) and during EX-induced CAS. In two pts the CAS involved a proximal segment of the left anterior descending coronary artery (LAD) and in the other 2 pts, it involved the mid right coronary (RCA).

Detailed analysis of the RNVGs revealed marked wall motion abnormalities during EX-induced CAS, involving predominantly the septum and the antero-lateral wall in the 2 pts with LAD spasm while in the 2 pts with RCA spasm the contraction abnormalities involved primarily diaphragmatic segments. In the pts with LAD spasm LV ejection fraction (EF) decreased respectively from 51% and 70% at RT to 41% and 42% after EX. In the other 2 pts with RCA spasm EFs were 61% and 47% at RT and 62% and 50% respectively after EX. Repeat RNVG at RT, and with EX after nifedipine, demonstrated normalization of the CAS-induced contraction abnormalities.

Thus, CAS producing complete occlusion of a major coronary vessel results in segmental contraction abnormalities corresponding to the blood supply distribution. LAD spasm produces profound deleterious effect on global LV function as reflected by decreased EX-EF in contrast with RCA spasm which results in minimal effect.

HAEMODYNAMIC EFFECTS OF HAEMATOCRIT REDUCTION IN PATIENTS WITH CYANOTIC CONGENITAL HEART DISEASE AND SECONDARY POLYCYTHAEMIA.
Paul Oldershaw MRCP and Martin St. John Sutton MRCP. Brompton Hospital, London. SW3 6HP.

Patients with cyanotic congenital heart disease and secondary polycythaemia are subjectively improved by venesection. We have studied six such patients, both at rest and during exercise, to see if this subjective improvement is matched by haemodynamic changes. Haemoglobin concentration fell from 22.4±0.5g/dl (mean±SEM) to 18.8±0.5g/dl ($p<0.01$) 3 days after venesection with intravenous plasma replacement. Cardiac index, measured using the Fick Principle, increased from 2.2±0.1L/min/m^2 pre-venesection (Pr-V) to 2.9±0.2L/min/m^2 3 days post-venesection (Po-V), ($p<0.01$), without changes in resting heart rate. Exercise testing, using a cycle ergometer, showed an increase in maximal exercise capacity from 333±30Kpm/min Pr-V to 500±48Kpm PoV ($p<0.01$). During a constant work-load exercise test of six minutes duration, a greater mean cardiac index was produced post-venesection in response to the same work-load (6.7±.4L/min Pr-V, 7.3±.3L/min Po-V; $p<0.05$). Oxygen uptake during this test was also significantly increased (1053±69ml/min Pr-V, 1209±74ml/min Po-V; $p<0.05$) and oxygen debt reduced (863±68ml Pr-V, 622±78ml Po-V; $p<0.05$). Similar studies were performed at 14 days post-venesection; the above changes were maintained. These results show that the subjective improvement in cyanotic patients post-venesection is matched by objective circulatory changes, demonstrable both at rest and during exercise.

20 MONTH EXPERIENCE IN OUTPATIENT CARDIAC CATHETERIZATION. Earl S. Perrigo, M.D., Michael L. Kuehne, M.S., Francesco Michienzi, M.D., F.A.C.S. The Michienzi Medical Center, Sandusky, Ohio.

In a 20 month period, 224 cardiac catheterizations (209 brachial, 15 femoral) with coronary angiography were performed in this non-hospital outpatient laboratory. Catheterization revealed 119 (53%) patients with significant CAD, 31 (14%) with valvular heart disease, 9 (4%) with congenital heart disease, and 9 (4%) with cardiomyopathy. Following catheterization, 103 (46%) patients were placed on specific medical therapy and 55 (25%) were referred for cardiac surgical therapy. Quality of service was assured through the regular review of case reports and angiographic films by outside consultants and through submission of the data to a Cooperative Study of outpatient cardiac catheterization. There was a 2.6% complication rate with two diminished brachial pulses requiring surgical restoration and 4 catheterization induced arrhythmias requiring cardioversion. There were no catheterization related deaths. Cost of outpatient catheterization was found to be approximately 20% less than inpatient catheterization. Patients and families generally indicated a preference for this non-hospital setting. This study demonstrates that the non-hospital outpatient performance of cardiac catheterization does not compromise quality or safety of service, is cost effective, and has good patient acceptability.

INHIBITION OF LEUKOCYTE MIGRATION BY MONONUCLEAR CELL SUPERNATANTS FROM PATIENTS WITH ISCHEMIC HEART DISEASE. Sunil K. Das, M.D.; Leonard D. Stein, M.D.; Russell T. Reynolds, M.S.; Paulette J. Thebert, B.S.; James T. Cassidy, M.D., Departments of Medicine and Pediatrics, University of Michigan, Ann Arbor, MI.

Although Immunologic abnormalities have been observed in patients with various forms of ischemic heart disease (IHD), their clinical significance remain unknown. The present study examined in-vitro correlates of cell-mediated immunity (CMI) in 12 patients with unstable angina (UA); 5 with stable angina (SA); 12 with myocardial infarction (MI), 9 with MI < 1 year, 3 with MI > 1 year; and 12 control subjects (C). The indirect agarose leukocyte migration inhibition factor test was performed with the culture supernatants from peripheral blood mononuclear cells exposed to human heart extracts (HE) and concanavalin A (con A). Leukocyte migration inhibition (LMI) was present in response to HE for 6 of 12 (50%) patients with UA, 3 of 5 (60%) with SA, 5 of 12 (42%) with MI, and 1 of 12 (8%) of C. Migration indices ($\bar{X} \pm SD$) for these groups were measured at 0.9 ± 0.16 for UA, 0.88 ± 0.14 for SA, 0.9 ± 0.17 for MI, and 0.97 ± 0.1 for C ($P < 0.05$ between test groups and C). All patient groups had normal con A stimulated LMI. Thus LMI in response to HE stimulation provides additional evidence of altered immune response in patients with IHD probably related to previous or ongoing myocardial damage.

ACCELERATED CORONARY ATHEROSCLEROSIS FOLLOWING CARDIAC TRANSPLANTATION: SIGNIFICANCE OF HYPERCHOLESTEROLEMIA M.L. Hess, M.D., Andrea Hastillo, M.D., FACC, T.C. Wolfgang, MD, R.R. Lower, MD, Medical College of Virginia, Richmond, VA.

The significance of hypercholesterolemia in the development of accelerated atherosclerosis in patients following cardiac transplantation (CT) is unknown. To possibly identify those CT patients at increased risk for the development of accelerated coronary artery disease (CAD), total cholesterol (C), high density lipoprotein cholesterol (HDL) and the ratio of C/HDL were longitudinally followed in 15 long term survivors (>3 mos) of CT and correlated with graft function. Indications for CT: recurrent myocardial infarction (MI,n=7) and cardiomyopathy (CM,n=8). Preoperative C did not differ in the two groups (MI=201 ± 37; CM=151 ± 14 mg%, $p>0.2$) but HDL was lower in the MI group (29 ± 2.7 vs 46 ± 5.9 mg%, $p<0.05$) and R was greater (7.3 ± 1.3 vs 3.5 ± 0.3, $p < 0.05$). At one year post CT, both C and R were greater in the MI group (C: 350 ± 43 vs 221 ± 16 mg%, $p<0.05$; R: 6.8 ± 1.1 vs 3.8 ± 0.08, $p<0.05$). At two years post CT, C and R remained elevated in the MI group (C: 330 ± 29 vs 220 ± 11, $p<0.01$; R: 7.8 ± 0.8 vs 3.8 ± 0.8, $p<0.001$) and HDL was significantly decreased in the MI group (42.7 ± 2.0 vs 59.2 ± 6.0 mg%, $p<0.05$). All patients in the MI group and only one patient in the CM group developed either abnormal exercise thallium studies (segmental perfusion defects), gated pool scans (regional wall motion abnormalities) or myocardial infarction. It is concluded that the accelerated atherosclerosis of CT is associated with an increase in C and C/HDL ratio, that by two years post CT, patients with elevated C and R values demonstrate graft dysfunction with evidence of CAD and that patients transplanted for recurrent MI may be at increased risk for the development of accelerated CAD.

ECHOCARDIOGRAPHY: VENTRICULAR FUNCTION I
8:30-10:00

TWO-DIMENSIONAL ECHOCARDIOGRAPHIC MEASUREMENT OF EJECTION FRACTION: WHAT DETERMINES A GOOD CORRELATION? R. Brad Stamm, MD; Douglas L. Mayers, MD; Randolph P. Martin, MD, University of Virginia, Charlottesville, Va.

An estimate of left ventricular ejection fraction (EF) is often used. We performed two-dimensional echocardiography (2DE) on 45 patients 24 hours prior to ventriculography (LVG) to assess a) whether trained echocardiographers could accurately estimate EF, b) which measured 2DE formula correlated best with LVG, and, c) to determine if the quality of the 2DE study affected the EF. Three blinded readers estimated EF using all standard 2DE views. Additionally calculated area, diameter and length was measured from parasternal short axis and apical views. 2DE quality was graded good and poor. Correlation with LVG follows:

All patients N = 45	Patients Measured		Good Quality Studies Only		Poor Quality Studies Only	
	N	r	N	r	N	r
Estimated	45	.93	20	.94	25	.91
Simpsons	21	.93	16	.93	5	.84
Ellip Biplane 4	35	.85	16	.84	19	.91
Ellip Biplane 2	13	.91	11	.92	too few	
Ellip Uniplane 4	42	.87	20	.92	22	.80
Ellip Uniplane 2	17	.86	12	.90	5	.43
Short Ellipse	36	.87	20	.95	16	.74
Apical Diameters	17	.81	13	.89	too few	
Teicholz	36	.74	20	.76	16	.77
Length Estimate	34	.80	20	.83	14	.78

p=0.01 for all r

We conclude that a highly accurate 2DE estimate of EF can be made by trained observers; the estimated EF was obtained in all patients and was not affected by echo quality. The biplane echo formulas are the most accurate but they are adversely affected by echo quality and cannot be obtained in all patients.

HETEROGENEITY OF SEGMENTAL LEFT VENTRICULAR WALL THICKENING AND EXCURSION IN TWO-DIMENSIONAL ECHOCARDIOGRAMS OF NORMAL HUMANS. Natesa Pandian, MD; David Skorton, MD; Steve Collins, PhD; Ed Burke, PhD; Herman Falsetti, MD, FACC; Richard Kerber, MD, FACC, CV Cent, Univ of Iowa, Iowa City, Iowa.

Segmental abnormalities of left ventricular (LV) wall thickening and excursion have been demonstrated by 2-D echo (2DE) in ischemic heart disease, but the variability of segmental dynamics in normals has not been defined. We performed 2DE on 12 normal male subjects, age 19-27. Short-axis images at mitral valve (MV), chordal (CH) and papillary muscle (PM) levels were obtained at end-diastole and end-systole. Radii were drawn dividing each image into 12 equal segments. 420 segments were analyzed. % systolic wall thickening along each radius, and % area change of each cavity segment were determined, using a computerized analysis which corrected for cardiac rotation and translation. Variability was measured as the range of thickening or segmental area change % (highest-to-lowest) for each subject at each level. Average range for all subjects at each level is expressed as "mean range". Results: We saw greater than 15% cavity area change and greater than 20% systolic thickening in 95% of all segments analyzed.

	Wall Thickening (%)			Cavity Segment Area Change(%)		
Level	Mean	S.D.	Mean Range	Mean	S.D.	Mean Range
MV	53	27	76	44	16	32
CH	50	23	61	47	21	53
PM	53	23	64	52	20	43

Correction for cardiac rotation and translational motion within the thorax did not alter these results. Conclusions: 1) There is considerable intersegmental variability of LV dynamics in normals on 2DE. 2) Marked differences in thickening and wall excursion may occur in adjacent segments in normals, and therefore such differences alone do not indicate ischemic heart disease.

ACCURACY OF M-MODE ECHO MEASUREMENTS OF THE LEFT VENTRICLE. Mark J. Friedman, MD, FACC, William R. Roeske, MD, FACC, David J. Sahn, MD, FACC, Stanley J. Goldberg, MD, FACC. University of Arizona; Tucson, Arizona.
Although the minor diameter of the LV can be measured from an M-mode echo, criteria for measuring end diastolic diameter (EDD) & end systolic diameter (ESD) are controversial. Therefore, we simultaneously recorded an M-mode echo & sonomicrometer crystal signals & measured the LV in 12 instrumented open chested dogs. Crystals were placed on the endocardial surface of the septum & the LV posterior wall at the chordal level. An M-mode echo of the septum & posterior wall was obtained from the same level. M-mode echo EDD was measured at the onset of the QRS (EDD-Q), at the peak of the R-wave (EDD-R), & as the largest diameter (EDD-L). M-mode echo ESD was measured from the posterior motion of the septum (ESD-VS), from the anterior motion of the posterior wall (ESD-PW), and as the smallest diameter (ESD-S). Fractional shortening for all pairs of EDD & ESD was compared to crystal fractional shortening. EDD-Q (mean ± SD; 4.04±.6) and EDD-R (4.02±.6) were the same as crystal EDD (4.02±.7). However, EDD-L (4.34±.6) was larger than crystal EDD ($p < 0.01$). ESD-VS (3.25±.6) was the same as crystal ESD (3.28 ±.7). However, ESD-PW (3.21±.6) and ESD-S (3.0±.6) were smaller than crystal ESD ($p<0.05$ & $p<0.01$). Fractional shortening using EDD-Q or EDD-R with ESD-VS or ESD-PW was not different from crystal fractional shortening (.19 ± .05). All fractional shortening measurements using EDD-L or ESD-S were larger than crystal fractional shortening ($p<0.01$). CONCLUSION: M-mode echo EDD-Q or EDD-R and ESD-VS are best for estimating LV dimension & fractional shortening. These data support the recommendations of the American Society of Echocardiography in attempting to quantitate LV minor axis dimensions from the M-mode echo.

COLD PRESSOR ECHOCARDIOGRAPHY
Roberta G. Kurtz, M.D., Assoc., Mary Sue LeMire, RT., Robin Chene, Marie Stacewicz, Bertram Pitt, M.D., FACC, University of Michigan Medical Center, Ann Arbor, MI

M-Mode echocardiography has found wide application for the detection of resting left ventricular dysfunction (LVD). Although exercise (Ex) has also been found useful in evaluating patients with latent LVD, it has not found wide application because of technical difficulty. Recently Cold Pressor (CP) radionuclide ventriculography (RNV) has been proposed as an alternative to ExRNV and found to have a $> 90\%$ sensitivity and specificity for detecting latent LVD. A normal CPRNV is a $< .03$ absolute decrease in LV ejection fraction (EF) from a resting value of $\geq .50$ and no wall motion abnormality. The same criteria for a normal CP echo was used, calculating LVEF by the Teichholtz formula. Ten patients were evaluated by both CP Echo and CPRNV. Both CP Echo and CPRNV were normal in 3 and abnormal in 5 patients. Two patients had abnormal CP Echo but normal CPRNV, 1 with ergonovine proven coronary artery spasm of the left circumflex artery and the other with constrictive pericarditis, mitral valve prolapse, and normal coronary arteries. Thus, CP Echo may be a useful technique for detecting latent LVD without many of the technical difficulties encountered with Ex echocardiography.

SIMULTANEOUS CONTRAST TWO-DIMENSIONAL ECHOCARDIOGRAPHY AND CONTRAST VENTRICULOGRAPHY: DISCREPANCIES IN LEFT VENTRICULAR VOLUME
Michael J. Barrett, MD; Larry Jacobs; Jonathan Gomberg; Lynn Horton; Steven G. Meister, MD, FACC, The Medical College of Pennsylvania, Philadelphia, PA.

Previous non-simultaneous studies demonstrate the left ventricular volume (LVV) by two-dimensional echocardiography (2D Echo) differs significantly from that obtained by contrast ventriculography (CV). To investigate this problem, we performed simultaneous contrast 2D Echo and CV on 19 cardiac cycles in 8 patients. CV was recorded in the 30° right anterior oblique view simultaneous with contrast 2D Echo in the apical long axis view during a power injection of 45 cc of 76% Renografin. Independent observers traced the ventricular outlines in each technique and simultaneous beats were then matched. All perimeters of ventricular size were underestimated by 2D Echo compared to CV: Cavity length by 16.0% ± 2.9 (M ± SEM) ($p<.001$) endocardial area by 32.6% ± 3.5%, ($p<.001$) and ventricular volume by 40.5% ± 5.4, ($p<.001$). Linear regression analysis yielded a good correlation of stroke volume ($r=0.88$, SEE=15.6 cc) and ejection fraction ($r=0.90$, SEE=.08) between 2D Echo and CV. Since there was no fluctuation in LVV between studies and excellent endocardial definition by contrast 2D Echo, none of these errors can be attributed to these sources. However, previous studies in phantom hearts have shown 2D Echo increases apparent wall thickness with consequent reduction in cavity size. This reduction in cavity size may account for the observed differences in LVV between these two techniques. Conclusion: Simultaneous contrast imaging shows 2D Echo underestimates ventricular volume by 40% compared to contrast ventriculography. Regression equations permit an accurate calculation of stroke volume and ejection fraction by 2D Echo.

INFERIOR VENA CAVAL ULTRASONAGRAPHY: ITS USE IN THE ASSESMENT OF RIGHT HEART FUNCTION
Gary S. Mintz MD, FACC, Morris N. Kotler MD, FACC, Wayne R. Parry, Abdulmassih S. Iskandrian MD, FACC, Sally A. Kane RN, Cardiovascular Institute, Hahnemann Medical College, Philadelphia, Pennsylvania

We studied the inferior vena cava (IVC) as an index of right heart function. A two-dimensional echo sector visualized the IVC and its M-mode cursor generated a time-motion record of IVC size and pulsation. In 10 normal patients, small presystolic ("A") and systolic ("V") waves were recorded; the normal "A" wave was <125% and the normal "V" wave <140% end diastolic IVC dimension. Inspiration normally caused >50% decrease in IVC dimension. Seventy patients with mitral valve disease, coronary artery disease, or atrial septal defect had right heart catheterization, contrast RV angiography, and/or radionuclide RV angiography. The "A" wave was absent in the 31 patients with atrial fibrillation. When normalized for body surface area, end diastolic IVC dimension correlated with RA pressure ($R=0.72$, $P\leq 0.001$). An "A" wave $\geq$125% end diastolic IVC dimension occurred in 9 of 12 patients with RV end diastolic pressure $\geq$10mmHg, but in none <10mmHg ($P<0.001$). A "V" wave$\geq$140% end diastolic IVC dimension occurred in 8 of 11 patients with significant tricuspid insufficiency, but in no patient with mild or no tricuspid insufficiency ($P\leq 0.001$). Lack of respiratory variation in end diastolic IVC dimension occurred in severe RV dysfunction (radionuclide RV ejection fraction <25%); inspiratory decrease of IVC dimension correlated with RV ejection fraction ($R=0.75$, $P<0.001$). We conclude that echocardiographic assessment of IVC size and pulsation is an important index of right heart function: (1)IVC size correlates with RA pressure, (2) a large "A" wave predicts a high RV end diastolic pressure, (3) a large "V" wave predicts significant tricuspid insufficiency, and (4) lack of respiratory variation in IVC size predicts severe RV dusfunction.

NUCLEAR CARDIOLOGY: EVALUATION OF CARDIAC FUNCTION
10:30-12:00

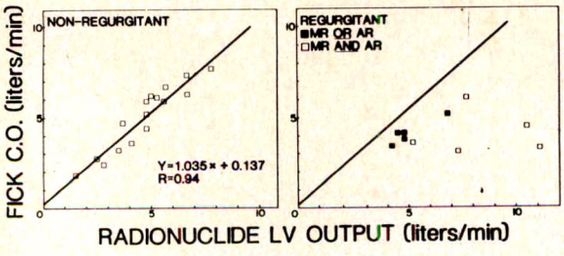
DIRECT MEASUREMENT OF CARDIAC OUTPUT BY GATED EQUILIBRIUM BLOOD POOL SCINTIGRAPHY. G.J. Dehmer, MD, B.G. Firth, MD, S.E. Lewis, MD, J.T. Willerson, MD,FACC, L.D. Hillis, MD, FACC, U of Texas Health Science Center, Dallas, TX

We have previously described a non-geometric technique for the determination of LV volumes from the count data derived from gated equilibrium blood pool scans (GS) and have validated this technique by demonstrating an excellent correlation between scintigraphically and angiographically-determined LV volumes. To provide further prospective evaluation of this method and to validate its ability to determine stroke volume (SV) and cardiac output (CO) by a technique independent of geometric assumptions, simultaneous measurement of CO by thermodilution (THD) technique and GS was performed in 21 patients (pts) without valvular regurgitation or intracardiac shunting. During an imaging period of 6-8 mins, CO was measured by THD every 1½ mins, and the average of 3-5 THD COs was correlated with the GS CO (obtained by multiplying heart rate by the derived SV {end-diastolic volume minus end-systolic volume}). To validate further the reliability of GS measurements at high COs, 7 pts had multiple measurements of CO at rest and during isoproterenol infusion (1-4 micrograms/min). There was an excellent correlation between THD and GS CO (GS CO = 0.99 THD CO - 0.005 L/min; n=31, SEE=0.175 L, r=0.97) as well as between THD and GS SV (GS SV = 1.03 THD SV - 2.8 ml; n=31, SEE=2.5 ml, r=0.95). In addition, the correlation between GS and angiographic measurements of LV volumes continued to be excellent: in 15 pts with technically adequate angiograms, GS LV volume = 0.90 (Angiographic LV volume) + 7 ml; n=30, SEE=10 ml, r=0.91. Thus, this study further validates the non-geometric method of measuring LV volumes by gated scintigraphy and demonstrates its ability to measure LV stroke volume and cardiac output reliably.

QUANTITATION OF LEFT VENTRICULAR OUTPUT IN PATIENTS WITH AND WITHOUT LEFT-SIDED VALVULAR REGURGITATION USING EQUILIBRIUM RADIONUCLIDE VENTRICULOGRAPHY

Marvin A. Konstam, MD; Joshua Wynne, MD, FACC; B. Leonard Holman, MD, FACC; Edward J. Brown, MD; Jane M. Neill; Joseph F. Kozlowski, Harvard Medical School and Brigham and Women's Hospital, Boston, MA

We examined the accuracy with which LV output can be estimated by radionuclide ventriculography. Following in vivo red blood cell labeling, we measured LV end-diastolic and end-systolic count rates and the count rate in 5 ml of patient's blood. After estimating the average ratio of counting efficiency for the LV to counting efficiency for the blood sample (E_{LV}/E_S) in 6 patients, we calculated LV output in 26 other patients as LV activity ejected per minute (min) divided by activity per liter of blood divided by the previously estimated E_{LV}/E_S. Radionuclide LV output closely approximated Fick CO (r = 0.94) in patients without mitral or aortic regurgitation (MR or AR) and exceeded Fick CO in all patients with MR or AR. The radionuclide ventriculogram is an excellent means for noninvasive estimation of LV output.



ONE MINUTE MULTIPLE GATED EQUILIBRIUM SCINTIGRAPHY FOR ASSESSMENT OF LEFT VENTRICULAR EJECTION FRACTION AND SEGMENTAL WALL MOTION: VALIDATION WITH STATE OF THE ART INSTRUMENTATION AND OPTIMIZED SPACE-TIME SMOOTHING

Ronald Levy, MD; Alan Rozanski, MD; David Brown, RT; Ken Van Train, RT; Ernest Garcia, PhD; Nancy Pantaleo , RN; Jamshid Maddahi, MD; Alan Waxman, MD; and Daniel Berman, MD, FACC. Cedars-Sinai Medical Center, Los Angeles, Ca.

Due to patient (pt) difficulty in sustaining peak bicycle exercise, shortened data acquisition time during multiple gated equilibrium scintigraphy (MGES) is desirable. Thus, in 14 consecutive pts undergoing MGES, we determined whether state-of-the-art instrumentation, including use of a camera with a ¼ inch crystal and high fidelity computer video display, and enhanced image processing permit the accurate assessment of LV ejection fraction (EF) and segmental wall motion (SWM) from data collected over only 1 minute (min). Following acquisition of consecutive 1, 2, and 1 min images in the 45° LAO view, an optimized space-time smoothing algorithm was applied. LVEF's were determined in a blinded fashion by an experienced operator, using light pen assignment of the LV and background regions. A second operator determined LVEFs on the first 1 min study. SWM was separately evaluated by 2 blinded observers using a 5 point scoring system (3=normal, -1=dyskinesis). Differences >1 were considered disagreement. A high correlation was found between 1 and 2 min LVEFs (r=.86). Intraobserver agreement of 1 min LVEFs was also high (r=.89), as was interobserver agreement (r=.91). With respect to SWM, 92% agreement for 1 and 2 min studies and 99% agreement for consecutive 1 min studies was found. Interobserver agreement for SWM was 98% in 1 min studies. Thus, with recent technical advances, it is possible to accurately assess LVEF and SWM from 1 min multiple gated scintigraphic studies. This improvement should enhance evaluation of LV performance during peak bicycle exercise.

RADIONUCLIDE DETERMINATION OF LEFT VENTRICULAR VOLUME: COMPARISON OF COUNTS-BASED AND GEOMETRIC METHODS.

Barry Massie, MD, FACC and Barry Kramer, MD. VA Hospital and University of California, San Francisco, CA.

Recently, several methods have been proposed for the scintigraphic determination of left ventricular (LV) volume. To compare their accuracy, we measured LV volume by: 1) LAO COUNTS: a counts-based method employing left anterior oblique (LAO) blood pool scintigrams and an externally counted blood sample reference; 2) RAO GEOM: a geometric method employing measured long and short axes from first pass right anterior oblique (RAO) scintigrams and a calibrated reference grid; 3) BIPLANE GEOM: a geometric method using measured long and short axes from the first pass RAO scintigram and a second short axis from the LAO blood pool study. A single crystal gamma camera and commercially available analysis system were utilized. The radionuclide findings were correlated with RAO area-length volumes from LV angiography performed within 48 hours in 18 patients whose end-diastolic and end-systolic volumes (EDV and ESV) ranged from 89-328 and 12-161 ml, respectively.

	LAO COUNTS		RAO GEOM		BIPLANE GEOM	
	R	SEE	R	SEE	R	SEE
EDV	.96	17	.85	35	.88	29
ESV	.95	15	.91	20	.88	25
Combined	.98	16	.93	26	.94	24

R=correlation coef.; SEE=std. error of estimate (ml)

While all 3 methods yielded highly significant correlations for EDV, ESV and both volumes together ($p<.001$ for each), the LAO counts-based method was clearly superior. Since this method also allows multiple determinations following the administration of a single dose of radioactivity (such as at rest and with exercise or pre and post-intervention), we conclude that it is the method of choice for measurement of LV volumes.

THE DETECTION OF ABNORMAL PULMONARY CAPILLARY WEDGE PRESSURE FROM THE DISTRIBUTION OF REGIONAL PULMONARY BLOOD VOLUME ON THE GATED BLOOD POOL SCAN

Adalberto Urbina, MD; Robert D. Okada, MD, FACC; Mary D. Osbakken, MD; Charles A. Boucher, MD, FACC; Gerald M. Pohost, MD, FACC; H. William Strauss, MD, FACC; Igor Palacios, MD, Massachusetts General Hospital, Boston, MA

To determine if the apex-to-base relative distribution of pulmonary blood volume obtained from gated blood pool scans could be used as a noninvasive method to estimate pulmonary capillary wedge pressure (PCWP), 77 patients had PCWP determination at cardiac catheterization and gated blood pool scans within 15 days of catheterization (47% within 24 hours, including 10 simultaneous measurements). The relative distribution of pulmonary blood volume at the apex and base of the lung was determined from the end-systolic left anterior oblique view frame by placing equal-sized regions-of-interest over the right lung. Apex counts divided by base counts (A/B ratio) was considered abnormal if >1. Ejection fraction (EF) was also calculated from the gated blood pool scan and considered abnormal if <45%. The PCWP was considered normal if ≤12 mm Hg and abnormal if >12 mm Hg.

	A/B Ratio			EF	
	Normal	Abnormal		Normal	Abnormal
PCWP			PCWP		
Abnormal	5	21	Abnormal	9	17
Normal	45	6	Normal	32	19

The sensitivities of the A/B ratio and EF for an abnormal PCWP were 80% and 65% respectively, and the specificities 88% and 62%. These data suggest that the A/B ratio can be reliably used to differentiate normal from abnormal PCWP.

CORRELATION OF CINEANGIOGRAPHY AND BLOOD POOL SCAN FOR MEASUREMENT OF LEFT VENTRICULAR VOLUME IN HUMAN CADAVER HEARTS

Igor Palacios, MD; Mark R. Goldman, MD, FACC; Thomas Aretz, MD; Charles A. Boucher, MD, FACC; Robert D. Okada, MD, FACC; Mary D. Osbakken, MD, PhD; John Newell; Marsha Leavitt, Peter C. Block, MD, FACC, Massachusetts General Hospital, Boston, MA

The area-length method is widely used in the determination of left ventricular volume (LVV). Although previous studies have reported that this technique overestimates the true volume (TV), it is unknown whether this overestimation is the same at different volumes. In the present study using 10 post-mortem hearts, LVV were determined by both biplane right and left anterior oblique (RAO-LAO) cine ventriculography (LVA) and biplane RAO-LAO Technetium blood pool scans (LVR) and the results were correlated with TV. LV was made water tight by suturing the mitral valve leaflets, cross clamping the aortic root at the level of the aortic valve and ligation of the coronary ostia. Increases in LVV (10-150 ml) were obtained in each heart by step wise increments of known amounts of contrast material mixed with 99m Technetium injected through a cannula placed in the LV apex. Both LVA and LVR were determined at each volume. LVA correlated well with TV (R = 0.98). LVR correlated well with TV (R = 0.97). LVR correlated well with LVA (R = 0.96). Both techniques resulted in overestimation of TV with an upward shift of the regression line of 37.3 ml ± 10 (SEM) for LVA and 23.6 ml for LVR. The percent overestimation error was significantly greater at smaller LVV (error = 33% at TV = 30 ml and 10% at TV = 100 ml, $p<0.001$). Thus: (1) the percent error in the determination of LVV is proportional to 1/TV and (2) LVV can be reliably obtained from both LVR and LVA using the area-length method.

PLATELET ACTIVITY AND INHIBITION: EXPERIMENTAL AND CLINICAL OBSERVATIONS
10:30-12:00

FAILURE OF ASPIRIN TO PREVENT INCORPORATION OF INDIUM LABELLED PLATELETS INTO CARDIAC THROMBI IN MAN

A. Chadwick Cox, PhD; Michael D. Ezekowitz, MD, FACC, University of Oklahoma Health Sciences Center, Oklahoma City, Okla.

The purpose of this investigation was to study in vivo and in vitro platelet function in aspirin and non-aspirin treated patients with cardiac thrombi. In vitro function was tested by examining the aggregation response of platelets to ADP (1.6 μg/ml) and collagen (2 μg/ml); in vivo function, by examining the incorporation of Indium-111 labelled platelets into cardiac thrombi using gamma camera imaging. Eight patients with left ventricular aneurysms and mural thrombi were studied. Four patients were treated with aspirin in doses of 300 to 1200 mg/day. The remaining 4 patients were non-aspirin treated controls. Prior to Indium labelling of platelets, the aspirin dose significantly reduced the average percent total aggregation induced by collagen and ADP ($P<.02$); 54 and 76% aggregation for control group versus 29 and 67% for aspirin group. Most of this aggregability was retained after Indium-111 labelling as was the significant differences between the groups; 53 and 68% for the control group and 17 and 54% for the aspirin group. The autologous labelled platelets were incorporated into ventricular thrombi in all patients as evidenced by Indium-111 scintigraphy. We conclude that in spite of demonstrating the expected inhibitory effect of aspirin on platelet aggregation, these aspirin impaired platelets participated in active cardiac thrombosis in vivo.

EFFECT OF IBUPROFEN ON PLATELET DEPOSITION IN GORE-TEX AND AUTOLOGOUS VEIN GRAFTS

Kevin R. Kopesky, BA; Mrinal K. Dewanjee, PhD; Meng F. Lim, BS; Michael P. Kaye, MD, FACC, Mayo Clinic and Foundation, Rochester, MN

To quantitatively study platelet deposition on arterial prostheses and the effect of platelet inhibitory therapy with ibuprofen, 22 dogs underwent bilateral femoral artery grafting with one polytetrafluoroethylene (Gore-Tex) and one autologous vein graft. Seven dogs received 12.5 mg/kg ibuprofen intravenously, 15 minutes prior to arterial clamping; 6 dogs 400 mg orally every 8 hours for 48 hours, last dose 2 hours preop; and 9 dogs were untreated. Using autologous indium-111-labeled platelets injected 12 hours prior to operation as a platelet marker, grafts were removed 1 hour following resumption of blood flow. Radioactivity per unit weight was determined and compared with radioactivity per unit weight of blood. Synthetic and autologous grafts were then compared.

	Gore-Tex/ Blood	Vein/ Blood	Gore-Tex/ Vein
Control	19.70±5.40	3.02±1.77	11.20±4.11
IV Ibuprofen	1.48±0.72	1.09±0.57	1.70±1.32
Oral Ibuprofen	1.30±0.51	1.06±0.43	1.63±1.06

Ibuprofen treated dogs (IV and oral) had a 12-fold reduction in platelet deposition on Gore-Tex grafts and a 3-fold reduction on venous grafts. Platelet deposition was reduced significantly in Gore-Tex grafts ($P<0.001$) to a level comparable to that in autologous veins.

PLATELET THROMBUS FORMATION IN STENOSED CANINE CORONARY ARTERIES AND THEIR INHIBITION WITH IBUPROFEN

John D. Folts, Ph. D.; Frank C. Bonebrake, BS; and Brian Bertha, Department of Medicine, University of Wisconsin Medical School, Madison, Wisconsin.

We have previously shown that platelet thrombi periodically form in mechanically stenosed dog circumflex (Circ) coronary arteries producing cyclical reductions in coronary flow (CRF) as measured with EMF flowmeter. In 17 open chest anesthetized dogs given a 70% stenosis of the circ, (which just abolishes the reactive hyperemic response (RH) to a 20 second complete occlusion), CRF occurred with an abrupt return to control levels. The CRF were reduced with 10 mg/kg and abolished with 15 mg/kg of Ibuprofen (I) (Motrin^{R}) IV. The CRF gradually returned after 30 to 45 minutes. Heart rate decreased from 113 $\pm$ 15 to 91 $\pm$ 19 beats/minute ($p < .01$) and in vitro platelet aggregation using ADP as the stimulus decreased from 63 $\pm$ 13 to 40 $\pm$ 7 light transmission units ($p < .01$) with the 15 mg/kg of I. Plasma epinephrine (E) = 574 $\pm$ 149 pgm/ml and norepinephrine (NE) = 197 $\pm$ 62 pgm/ml before, and E = 259 $\pm$ 103 pgm/ml ($p < .01$) and NE = 138 $\pm$ 46 pgm/ml ($p < .05$) after the larger dose of I. We postulate that I temporarily inhibits prostaglandin synthesis, and subsequent platelet aggregation. The I lowers plasma E and NE and also heart rate, possibly by inhibiting prostaglandin synthesis in the adrenal medulla. With the reduced heart rate there was a small return of RH. We further postulate that the reduction in heart rate, plasma E and NE along with inhibition of CRF, if it occurs in man, would be beneficial to patients with coronary artery disease.

CONSISTENT PLATELET ACTIVATION ASSOCIATED WITH EARLY RECURRENT MYOCARDIAL INFARCTION

Alon Marmor, MD; William Schillizzi; Burton E. Sobel, MD, FACC; and Robert Roberts, MD, FACC, Washington University, St. Louis, Missouri

We have recently shown that patients with subendocardial myocardial infarction (MI) have a high incidence (43%, n=58) of early recurrent infarction (ERI) within 14 days, manifested by re-elevation of plasma MB CK, serum myoglobin and by new left ventricular wall motion abnormalities. In the present study participation of platelets in this process was evaluated by serial studies of these parameters coupled with prospective, serial assays of platelet factor IV (PF IV), an index of platelet degranulation. Blood samples were obtained for 14 days at intervals of every 4 hr for 3 days and every 12 hr for the subsequent 11 days beginning at the time of admission for MI. If ERI was suspected clinically, sampling frequency was increased again to 4 hr intervals. Samples were analyzed for PF IV by radioimmunoassay. Values in normal subjects (n=10) and in patients with coronary disease without concurrent infarction (n=15) averaged 7 $\pm$ 1 (SD) and 14 $\pm$ 6 ng/ml, respectively with a coefficient of variation of <10%. All patients exhibited increased PF IV with the initial MI (>100 ng/ml), with a return of values to normal within 48 hr in every case. Each episode of documented ERI was temporally associated with re-elevation of PF IV (average peak re-elevation = 40 $\pm$ 10). The PF IV was always elevated in the first sample temporally associated with ERI. Although it is not yet clear whether the platelet factor IV elevations actually preceded the onset of cell death associated with ERI, it is clear from these data that platelet activation is a consistent and temporally associated concomitant of reinfarction and hence a potential contributor to the additional myocardial injury.

RED CELL INVOLVEMENT IN PLATELET THROMBI FORMED IN STENOSED CANINE CORONARY ARTERIES

John D. Folts, Ph.D., Al R. Kutchera, M.S., Frank C. Bonebrake, Brian G. Bertha, Kennedy W. Gilchrist, M.D. The University of Wisconsin Medical School, Madison, WI.

Platelet thrombi (Th) form every 5-15 minutes in mechanically stenosed dog circumflex coronary arteries producing cyclical reductions in blood flow, measured with (EMF) which can lead to acute myocardial ischemia and sudden death. To collect the Th to determine the morphology and composition of Th after heparinization, a silastic rubber "T" tube (T) was placed distal to the stenosis (S) and in line with the normal circumflex flow pattern. The side arm is clamped and blood flows through the S, T, and into the distal circumflex bed until a platelet thrombus forms. Then the distal side of the T tube is clamped and the side arm unclamped, diverting the blood flow coming through the stenosis, through the side arm, into a beaker of fixative, thus, collecting the Th. The collection is repeated many times in each dog. In 7 dogs a Th was collected every time the flow declined. The Th was prepared for light and scanning electron microscopy. On high magnification using Carstairs stain and fluoresceine conjugated antisera, fused platelets and red cells (RBCS), both intact and ruptured, are noted at the edges of Th. We postulate that turbulent blood flow or packing of RBCS proximal to, and in S, damages some RBCS, releasing RBCS' ADP which enhances platelet aggregation which in turn releases substances that lyse more RBCS. Thus a self-perpetuating Th formation mechanism may develop. This may also occur in man where RBCS may accumulate and may be packed together proximal to a tight coronary arterial stenosis leading to release of ADP from lysed RBCS, increased platelet thrombus formation, acute ischemia and sudden death.

PLATELET ACTIVITY IN CORONARY DISEASE , RELATIONSHIP TO SMOKING AND HYPERLIPIDEMIA .

Charles w. Pumphrey M.R.C.P. National Heart Hospital, London W1 U.K. Joan Dawes Ph.D. M.R.C. Radioimmunoassay Team, Edinburgh,Scotland.

Platelets cause both atherosclerosis and acute arterial thrombosis. It is uncertain whether the coronary risk factors activate platelets to cause accelerated atherosclerosis, or whether any increased platelet activity is secondary to established arterial disease. We have measured the plasma level of the platelet-specific protein beta-thromboglobulin (BTG) which is thought to reflect platelet activity and is constant in the clinical steady state. In a control group there is no difference in plasma BTG between smokers (31.8 $\pm$ 1.6 ng/ml n = 45) and non smokers (32.2 $\pm$ 1.2 ng/ml n = 56). Asymptomatic patients with hyperlipidemia had a similar BTG (32.8 $\pm$ 1.7 ng/ml n = 32). However patients with symptoms of ischaemic heart disease have a significantly elevated plasma BTG (40.7 $\pm$ 1.4 n = 104, $P < 0.01$). Patients with two or more risk factors have a significantly higher BTG (45.2 $\pm$ 2.2 ng/ml n = 47) than those with one or no identified risk factor present (37.1 $\pm$ 1.7 ng/ml n = 57, $P < 0.005$). We conclude that neither smoking nor the present of hyperlipidemia increase platelet activity. However patients with coronary disease have platelets activated by the established arterial disease, and the increased activity seen in patients with more risk factors is due to the presence of more extensive disease.

PEDIATRIC CARDIOLOGY—NON-INVASIVE STUDIES
10:30-12:00

PROSPECTIVE DIAGNOSIS OF CONOTRUNCAL MALFORMATIONS IN INFANTS USING SUBXIPHOID TWO-DIMENSIONAL ECHOCARDIOGRAPHY

Stephen P. Sanders, MD, Fredrick Z. Bierman, MD, Roberta G. Williams, MD, Children's Hospital Medical Center, Boston, MA. 02115

Subxiphoid two-dimensional echocardiography (S2DE) was successfully performed and interpreted prospectively in 90 of 94 infants, ages one day to 12 months (median - 21 days), with conotruncal malformations and d-ventricular loop proved at cardiac catheterization over a 17 month interval.

Eighty-nine of 90 patients (pts) (99%) were correctly included in the category of conotruncal malformations, and in 85 pts (94%) the specific lesion was correctly diagnosed. All 37 pts with d-transposition of the great arteries were correctly diagnosed based on great artery morphology and direct visualization of ventriculo-arterial connections. Nine of ten pts with double-outlet RV were recognized by the origin of at least "1½" great arteries from the RV. In the tenth pt a large main PA and patent ductus arteriosus were mistaken for the aortic arch. Tetralogy of Fallot (TOF) was correctly diagnosed in 29 of 31 pts and TOF with pulmonary atresia in 6 of 6 pts. Continuity between the RV and PA, with infundibular narrowing, was seen in all pts diagnosed as TOF, while discontinuity between the RV and PA characterized TOF with pulmonary atresia. Two pts with TOF were incorrectly diagnosed by S2DE: one as a large membranous ventricular septal defect, and one as TOF with pulmonary atresia. Five of six pts with truncus arteriosus communis were correctly diagnosed by demonstrating continuity between the PA's and the ascending portion of the truncus arteriosus. Limited examination of the sixth pt lead to the incorrect diagnosis of double-outlet RV.

By direct visualization of ventricular and conotruncal anatomy, S2DE permits accurate diagnosis of conotruncal malformations in infants.

THE USE OF FETAL ECHOCARDIOGRAPHY IN THE DIAGNOSIS AND MANAGEMENT OF ANTENATAL ARRHYTHMIAS

Charles S. Kleinman, MD; John C. Hobbins, MD; Diana C. Lynch; Richard Donnerstein, MD; C. Carl Jaffe, MD; Norman S. Talner, MD, Yale University School of Medicine, New Haven, CT

M-mode fetal echocardiography has been used to analyze the cardiac rhythms of 28 fetuses (24-40 weeks (wks) gestation) referred for evaluation of prenatal arrhythmias. Arrhythmias were documented in 23 (82%) cases. Heart rate, atrioventricular (A-V) contraction sequence, mitral valve motion, and postectopic pauses were studied. Atrial premature beats (APB's) were diagnosed in 14 cases (61%). The APB's had ceased in 9 at restudy later in gestation. In the remaining 5 cases APB's were noted at birth but resolved by the third day. Six fetuses had brief episodes of regular bradycardia which resolved later in pregnancy. Atrial flutter with varying A-V block and congestive heart failure (CHF) was diagnosed in one fetus at 38 weeks. Caesarian delivery and electrical cardioversion successfully treated this child. Severe CHF and paroxysmal supraventricular tachycardia were diagnosed immediately prior to the stillbirth of a hydropic infant. Complete A-V block was diagnosed in a 24 wk fetus. Fetal echocardiography may contribute to the diagnosis and management of fetal cardiac arrhythmias.

PULMONARY VALVE ATRESIA: DIAGNOSIS BY PULSE DOPPLER/ TWO-DIMENSIONAL ECHOCARDIOGRAPHY

Joan C. Korfhagen, B.A., RDMS, Richard A. Meyer, M.D., FACC, Samuel Kaplan, M.D., FACC, Children's Hospital Medical Center, Cincinnati, Ohio.

Pulmonary valve atresia with an intact ventricular septum (PA) constitutes a medical emergency in the newborn period. Prompt recognition and treatment of this ductal dependent lesion is crucial for the survival of these very fragile babies. With two-dimensional (2-D) echocardiography the pulmonary valve and right ventricle (RV), can be visualized. It is not possible with 2-D alone to determine whether there is complete obstruction to pulmonary flow. With combined pulsed Doppler and two-dimensional echocardiography (Dop-2D) flow through the right ventricular outflow tract (RVOT) and across the pulmonary valve can be assessed. Therefore 8 newborns with documented PA were evaluated by Dop-2D and compared to patients with pulmonary stenosis (PS) and normal RVOT. All patients with PA exhibited characteristically absent flow in the RV and RVOT. In addition the size of the RV and RVOT were estimated. Once the Doppler sample volume was beyond the valve a typical Doppler signal of continuous flow from a patent ductus arteriosus was detected. These patterns differed markedly from patients with severe PS or unobstructed RVOT. It now appears possible to accurately distinguish PA from PS at the bedside and greatly facilitate the management of these critically ill infants. We suggest that as our experience broadens using this technique, cardiac catheterization may be obviated, permitting immediate surgical intervention, and enhance the survival of these newborns.

CARDIAC INVOLVEMENT WITH KAWASAKI DISEASE IN CHILDREN FROM NEW ENGLAND

Kyung J. Chung, MD, FACC; Robert E. Rinaldi, MD; David R. Fulton, MD; Marshall B. Kreidberg, MD, FACC, Tufts University School of Medicine, Boston, Massachusetts.

Thirty seven patients (pts), ages 6 months to 11 years, meeting clinical criteria for Kawasaki Disease (KD) were studied prospectively during April-July, 1980. There were 23 males and 14 females. All but 4 pts were white (2 blacks, 1 oriental, 1 Indian). A protocol was designed for evaluation of cardiac involvement including ECG, cardiac enzymes, M-mode (Echo) and 2-dimensional (2-DE) echocardiogram. ASA (100 mg/kg/day) was given during the febrile period followed by 30 mg/kg/day for 10 weeks or longer if platelet counts were elevated. Angiocardiography to delineate coronary artery (CA) and LV asynergy was performed 2 months after onset of KD. Seventeen (46%) pts had abnormal Echo findings during acute phase; flat or decreased ventricular septal motion in 9, pericardial effusion in 6 and congestive heart failure (CHF) in 5 manifested by chamber dilatation, decreased shortening fraction and prolonged systolic time interval. Abnormal Echo findings returned to normal in 2-4 weeks except in 2 pts who continued to show CHF. Four pts (11%), all of whom had abnormal acute stage Echo, showed CA disease on 2-DE by 2 weeks after onset of KD. Three had coronary aneurysms and 1 had dilated CA. Of 28 pts undergoing angiographic study, 24 showed normal LV and CA anatomy. Three pts had coronary aneurysms and 1 had dilated CA with LV asynergy. All were accurately diagnosed by 2-DE. On the basis of our study, serial M-mode and 2-D echocardiograms were sufficient to rule out cardiac involvement in KD. Those who have abnormal echoes should have angiocardiography to further delineate cardiac pathology.

COMPUTERIZED AXIAL TOMOGRAPHY OF THE THORAX: SIZE OF RIGHT PULMONARY ARTERY IN RIGHT VENTRICULAR OUTFLOW TRACT OBSTRUCTION

Carol M. Cottrill, M.D., FACC, Gregory L. Johnson, M.D., FACC, Jacqueline A. Noonan, M.D., FACC, University of Kentucky, Lexington, Kentucky

Computerized Axial Tomography (CAT) scans of the thorax were performed in 22 children ranging in age from 7 weeks to 14 years (mean = 3.5 years) who weighed 6 pounds to 86 pounds (mean = 28 pounds). The children had these cardiac lesions:

16 Tetralogy of Fallot (TOF), one post-op shunt
1 Pulmonary atresia with Intact Septum, post-op shunt
1 Complex RVOT Obstruction
1 Idiopathic Pulmonary Hypertension
3 No heart disease (NHD)

Structures were identified as follows: right pulmonary artery (RPA) 21/22, superior vena cava 21/22, right mainstem bronchus (RMB) 21/22, descending aorta 17/22, ascending aorta 10/22. These were measured and ratio of RPA diameter to RMB diameter was determined:

NHD	1.5 - 1.7
RVOT Obstruction - no shunts	< 1.5
RVOT Obstruction - with shunts	> 1.8
Pulmonary Hypertension	> 1.8

CAT scanning permits identification and measurement of RPA. This information may help plan surgical intervention.

MYOCARDIAL INFARCTION—A CLINICAL PATHOLOGIC SPECTRUM
10:30-12:00

RIGHT VENTRICULAR INFARCTION : CLINICAL COURSE AND FOLLOW-UP.

Victor Legrand, MD, Jean-Pierre Smeets, MD, Jean-Claude Demoulin, MD, Pierre Rigo, MD, Henri E. Kulbertus, MD, FACC, Section of Cardiology. University of Liège, Belgium.

Of 146 consecutive patients with inferior wall myocardial infarction (IWMI) submitted to Tc 99 m pyrophosphate scintigraphy, 34 (23 %) had concomitant right ventricular infarction (RVI) diagnosed by right ventricular Tc uptake. Gated blood pool scans (GBPS) performed in 14 cases showed right ventricular abnormalities in 12 (right ventricular asynergy : 8 ; right ventricular dilatation : 7 ; decreased right ventricular ejection fraction : 10).
Complications were common in the acute stage. Shock was noted in 14 cases, atrial fibrillation in 6, ventricular fibrillation in 6 and severe atrio-ventricular conduction disorders in 10. In-hospital mortality however was low (2 cases ; 5,9 %).
All patients were followed up for one year. 5 additional deaths occurred during follow-up (2 from cardiac failure ; 2 from recurrent MI, 1 from pulmonary embolism). Repeat GBPS at 3 months showed improved right ventricular ejection fraction and size in all but one of 12 cases. However, all 4 patients with large right ventricular infarction as judged from Tc 99 m pyrophosphate scintigraphy still had right ventricular enlargement and decreased right ventricular ejection fraction. Among 8 cases with smaller right ventricular infarction, only 2 still showed altered right ventricular function at 3 months.
Conclusions : 1) In spite of frequent complications in the acute stage, patients with right ventricular infarction have an overall good prognosis and long term outcome ; 2) those with extensive scintigraphic right ventricular lesions have more impressive and longer lasting hemodynamic disturbances.

RADIONUCLIDE EVALUATION OF RV AND LV FUNCTION (FX) IN CHILDREN-CINEANGIOGRAPHIC VALIDATION AND OBSERVATIONS IN TRANSPOSITION OF THE GREAT ARTERIES (TGA)

M.D. Parrish, MD, T.P. Graham, Jr.,MD, FACC, M.L. Born,MD, F.D. Rollo, MD, J. Weinberger, RN, O.H. Wolfe: Vanderbilt Univ. Med. CTR., Nashville, Tennessee 37232

Validation of an equilibrium radionuclide technique for assessment of RV and LV FX has not been reported in children with congenital heart disease (CHD). We performed resting equilibrium radionuclide ventriculograms (RVG's) in 19 children with diverse types of CHD (ages 4-19,mean 10yr), with exercise RVG's in 15 of the children. Cardiac catheterization (cath) was performed in 11 of 19 children within 2 weeks of RVG. Resting LV and RV ejection fractions (EF) from RVG and cath were compared by linear regression analysis: RVEF (cath vs RVG) r=0.83, S.E.E. 0.08, LVEF r= 0.88, S.E.E. 0.06, RVEF (TGA pts only) r= 0.98, S.E.E. 0.03. Inter observer correlations for RV and LV EF were 0.81and 0.98 respectively. With exercise, the interobserver correlations for RV and LV were 0.91and 0.93. Five pts with TGA had exercise studies: 2 with congenitally corrected TGA (CCTGA) and 3 with a mustard repair. The three TGA pts were all asymptomatic but only one had a normal increase in RVEF with exercise (0.53 to 0.78). One 18yr old with CCTGA with VSD, pulmonary stenosis and a Blalock-Taussig shunt had a normal exercise response, while an 11yr old with CCTGA and severe tricuspid incompetence had a fall in RVEF with peak exercise. We conclude that RV and LV EFs showed good correlations with cath EF's. Furthermore, we were able to perform this study in exercising children with no deterioration in inter-observer correlations. These techniques can provide important information regarding systemic ventricular FX in TGA, and aid in the long term evaluation of current methods of treatment for TGA and CCTGA.

SERIAL EVALUATION OF RIGHT VENTRICULAR FUNCTION AFTER RIGHT VENTRICULAR INFARCTION.

Tsunehiro Yasuda, MD; Robert Okada, MD, FACC; John B. Bingham, MB; Herman K. Gold, MD, FACC; Robert C. Leinbach, MD, FACC; Gerald M. Pohost, MD, FACC; H. William Strauss, MD, FACC, Massachusetts General Hospital, Boston, MA.

To define the course of right ventricular function after right ventricular myocardial infarction (MI), 61 patients with acute MI were studied initially within 18 hours after chest pain with multi-gated blood pool scans. Follow-up studies were performed at 90 minutes, 10 days and 3 months. In addition, symptom limited supine bicycle exercise was performed at 3 months post RV MI. Twenty of the 61 patients had abnormal RV regional wall motion on the initial multi-gated blood pool scan and were considered to have RV MI. The RV ejection fraction (EF) results are (mean ± 1 SD):

TIME	RVEF	
1) Initial	33.2 ± 13.0	p<.05
2) 90 minute	35.0 ± 14.6	
3) 10 days	45.7 ± 11.3	
4) 3 months	41.0 ± 16.6	
5) Pre-exercise	39.1 ± 8.82	
6) Maximum exercise	39.5 ± 12.0	

These data show that (1) RVEF improves within the first 10 days following RV MI, (2) There is no significant further improvement in RVEF 10 days to 3 months following RV MI, (3) Despite the early improvement in RVEF following RV MI, RV function was still abnormal at 3 months as demonstrated by a failure to increase RVEF with exercise.

NON TRANSMURAL (SUBENDOCARDIAL) MYOCARDIAL INFARCTION IN MAN: THE PREVALENCE OF TOTAL CORONARY OCCLUSION.
Marcus A. DeWood,M.D; Julie Spores,CRNA; Robert N. Notske, M.D,FACC; J. Paul Shields,M.D,FACC; Carroll Simpson,M.D, FACC; Samuel Selinger,M.D; William E. Shell,M.D.
Sacred Heart and Deaconess Medical Centers, Spokane, WA.

Total coronary occlusion is a frequent finding in transmural myocardial infarction. However, knowledge concerning the prevalence of total coronary occlusion during nontransmural myocardial infarction (NMI) has been acquired mostly from autopsy data. Few studies describe the occurrence of total coronary occlusion during NMI in patients (pts). From mid 1976 to mid 1980, 152 pts underwent left ventriculography and coronary arteriography (CA) within 96H of symptom onset of NMI characterized by substernal chest pain associated with 1) ST-T wave abnormalities not progressing to pathologic Q waves and 2) abnormal elevation of total CK activity prior to any intervention. The 152 pts were then grouped by subsets reflecting the time interval in hours (H) from peak symptoms to investigation by CA. Overall, the prevalance of total occlusion by CA was 44/152 (28.9%). Analysis of subsets indicated the following. *p=NS

0-24H	24-48H	48-72H	72-96H
18/88 (20.4%) *	11/31 (35.4%) *	9/21 (42.8%) *	6/12 (50%)

No pt had normal coronary arteries by CA. These data suggest 1) total coronary occlusion is infrequent in early nontransmural MI in man, 2) the prevalance of total occlusion appears to increase in pt groups over discrete time intervals and 3) severe alterations in coronary tone in conjunction with preexisting atherosclerotic plaque as opposed to total occlusion may be contributory to oxygen deprivation in early NMI.

TWO-DIMENSIONAL ECHOCARDIOGRAPHIC RECOGNITION OF SURGICALLY REMEDIABLE COMPLICATIONS OF ACUTE MYOCARDIAL INFARCTION
Gary S. Mintz MD, FACC, Mark F. Victor MD, Morris N. Kotler MD, FACC, Wayne R. Parry, Bernard L. Segal MD, FACC
Cardiovascular Institute, Hahnemann Medical College, Philadelphia, Pennsylvania

The appearance of a new systolic murmur in a patient (PT) with congestive heart failure following myocardial infarction suggests the presence of a surgically remediable structural defect. Survival depends on rapid accurate diagnosis leading to prompt definitive therapy. Using real-time two-dimensional echocardiography (2D-E) we studied 13 PTS who presented in this manner 3 days to 6 weeks after infarction. Four PTS had a ruptured papillary muscle (PM); 2D-E findings were a flail mitral leaflet with a mass attached by chordae to the tip of the leaflet and a truncated PM. All had severe angiographic mitral insufficiency and surgical confirmation of PM rupture. Five PTS had acute irreversible PM dysfunction. 2D-E showed increased density and immobility of the PM and dyskinetic LV wall motion involving and displacing the base of the PM. One of the mitral leaflets was retracted toward the LV apex. All PTS with acute PM dysfunction had severe angiographic mitral insufficiency and surgical confirmation of intact PM. Four PTS had a ventricular septal defect; 2D-E showed a localized septal aneurysm with a defect in septal continuity. At catheterization all had a large left-to-right shunt; 3 PTS had surgical confirmation of septal rupture (1 PT refused surgery).

We conclude: 2D-E is useful in studying PTS with a new systolic murmur and heart failure following myocardial infarction to detect remediable structural defects. Rapid diagnosis may lead to enhanced survival in these patients.

THE NONTRANSMURAL VS TRANSMURAL MYOCARDIAL INFARCTION: IS THERE A DIFFERENCE?
Edward H. Schuster, M.D., Alison Freifeld, B.A., and Bernadine H. Bulkley, M.D., F.A.C.C., The Johns Hopkins School of Medicine and Hospital, Baltimore, Maryland.

"Nontransmural" and "transmural" are morphologic terms used clinically to subset patients with myocardial infarction (MI), and controversy exists as to their meaning regarding clinical course. The purpose of this study was to identify true morphologic nontransmural acute (< 21 days old) infarcts at autopsy and compare them to age matched transmural (full-thickness) infarcts, for clinical and pathologic similarities and differences. Comparing 35 nontransmural to 35 transmural infarcts, there was no significant difference with regard to race, sex, chest pain, admission or worst Killip class, arrhythmias, heart block or cause of death; transmural MI's did have a higher frequency of new Q waves (30/35 vs 6/35, $p < .005$). At autopsy, there were no significant differences regarding heart weight, location or numbers of infarcts, severity of coronary disease, age of acute infarct, or size of infarction (18% of left ventricle for nontransmural vs 22% for transmural). Acute thrombi were significantly more common among tansmural MI's (30/35 vs 8/35, $p < .005$). Morphologically the nontransmural infarcts showed mural involvement ranging from 20 to 90% of left ventricle, and histologically showed more reflow (i.e. contraction band) injury (54% of total infarct) compared to transmural infarcts (35% of total) ($p < .05$).

Fatal nontransmural and transmural infarcts have major clinical and pathologic similarities, but differences in type of necrosis and occurrence of coronary thrombi suggest differing pathophysiology. The latter may account for existing differences among clinical studies regarding prognosis.

ANTERIOR TRANSMURAL MYOCARDIAL INFARCTION (AMI). ANALYSIS OF REGIONAL WALL MOTION DURING THE EARLY HOURS WITH AND WITHOUT TOTAL CORONARY OCCLUSION.
Marcus A. DeWood,M.D; J. Paul Shields,M.D, FACC; Gerald R. Hensley,M.D,FACC; Julie Spores,CRNA; Steve Smith,M.D; K.Riggs,M.D; L.Thomas Mouser,M.D,FACC; William P. O'Grady, M.D,FACC, Sacred Heart and Deaconess Medical Centers, Spokane, Washington.

Total coronary occlusion is frequently present during AMI. Although early thrombolysis or release of coronary spasm may occur, little is known concerning the effects of residual blood flow on regional wall motion (RWM) as reflected by regional ejection fraction (EF). We investigated RWM in normal subjects (N=30) and in 50 pts who underwent coronary arteriography and left ventriculography (LV) within 12H of AMI. Group I (N=25) demonstrated total occlusion of the proximal LAD. Group II (N=25) had residual antegrade flow in the LAD. Ventriculograms were divided from the mid aortic valve to the LV apex to obtain a long axis. The anterior wall (AW) of the LV was then divided into 4 equal sections from the apex (area 1) to the base (area 4). Areas 2 & 3 defined the midportion of the AW of the LV. End systolic (ES) and end diastolic (ED) measurements were then made and the difference (ED-ES/ED) expressed as REF in % area change.

*p<0.01	Area 1	Area 2	Area 3	Area 4
Normals	56±10	60±10	63±9	58±6
Group I	16.5±19*	18.1±12*	23.6±11*	36.2±11*
Group II	34.6±15	38.0±14	45.7±14	47.1±9

Thus: 1). RWM is depressed in both groups but residual blood flow is associated with significantly better RWM during the early hours of AMI and 2). Continued myocardial perfusion by patency of the LAD may lead to improved contractile performance.

INOTROPIC AND CHRONOTROPIC EFFECTS OF INSULIN IN THE CONSCIOUS DOG: CONTRIBUTION OF CATECHOLAMINES AND HYPOGLYCEMIA. Jud U. Doherty, MD; Chang-seng Liang, MD, PhD; Robert T. Faillace, MD; J. Mark Yi, PhD; Stephanie Arnold, BA; Haralambos Gavras, MD; William B. Hood, Jr., MD, FACC, Boston University School of Medicine and Thorndike Memorial Laboratory, Boston, Mass.

Insulin is known to exert an inotropic effect but the mechanism is unclear. To determine whether it is related to catecholamine release or hypoglycemia, we measured heart rate (HR), mean aortic blood pressure (BP), cardiac output (CO), left ventricular dP/dt, and plasma norepinephrine (NE) and epinephrine (E) at control (C), during infusion of 8 milliunits/kg/min of insulin (IN), and during IN plus restoration of plasma glucose (G) to control (IN+G), in 7 conscious, chronically instrumented dogs. Results were:

	HR	BP	dP/dt	CO	G
	bpm	mmHg	mmHg/sec,x10^{-3}	L/min	mg/dl
C	80±5	116±5	2.9±.13	1.68±.19	72±4
IN	96±9*	120±4	4.0±.23*	2.61±.22*	35±2*
IN+G	116±10*	117±2	4.3±.21*	2.98±.21*	72±4

Values are mean±SE; *P<0.05, compared to C.
NE and E increased significantly from 0.36±0.02 and 0.51±0.11 at C to 1.50±0.14 and 3.61±0.60 ng/ml during IN. In a second group (n=7) G was held constant throughout IN; IN increased HR (108±9 to 124±10 bpm), dP/dt (2950±210 to 4090±310 mm Hg/sec), and CO (1.60±0.11 to 2.02±0.20 L/min). In a third group (n=7) with IN+propranolol, BP increased from 121±6 to 140±10 mm Hg with no other changes. In a fourth group (n=7) with IN+propranolol+phentolamine, all hemodynamic changes were abolished. We conclude that IN has a positive inotropic and chronotropic effect which is independent of hypoglycemia and which is mediated by catecholamine release.

REVERSAL OF DIABETIC CARDIOMYOPATHY BY INSULIN TREATMENT Thomas Schaible, PhD; Alwyn Murphy; James Scheuer, MD, FACC, Montefiore Hosp-Albert Einstein Col of Med, Bronx, NY.

Our previous studies have shown isolated hearts from male rats made chronically diabetic (D) with streptozotocin (STZ) demonstrated abnormal contraction and relaxation. To ensure that this response was not due to toxic effects of STZ, rats that were D for 6 weeks were treated with insulin (2-3 units/day) for 15-25 days so that blood glucose was less than 200 mg%. Hearts from treated D animals (TD) were compared with hearts from untreated D animals (UD) (blood glucose > 500 mg%) and non-D control animals (C) in an isolated heart apparatus at left atrial pressures (AP) 5-20 cm H_2O and at fixed heart rates using 5.5 mM glucose as substrate. Means of 6-7 hearts at 15 cm AP were:

	CF[a]	PLVSP	+dP/dt	-dP/dt	MVO2[a]	SW[a]
	ml/min	mm Hg	mm Hg/sec	mm Hg/sec	ml O_2/min	ergs 10^5
UD	109	82	3530	-2370	1.19	1.27
TD	91[1]	99[1]	4710[1]	-2720	1.37	1.53[1]
C	96[2]	94	4260[2]	-2920[2]	1.28	1.40

(CF = coronary flow; SW = stroke work; a = per gram dry LV wt; 1 = $p<.05$, UD vs TD; 2 = $p<.05$, UD vs C)
Increasing AP from 10 to 20 cm resulted in no increase in CO in UD, a 28% increase ($p<.005$) in TD and a 15% increase ($p<.001$) in C. Therefore, the abnormalities in performance of hearts of STZ diabetic rats are reversed by chronic insulin therapy and are not the result of STZ cardiotoxicity. Furthermore, the trend for higher values of PLVSP, +dP/dt and SW in TD compared to C suggests a beneficial effect of chronic insulin therapy on the myocardium.

PROTECTIVE EFFECTS OF VERAPAMIL AND HYDRALAZINE ON THE CARDIOMYOPATHY OF THE SYRIAN HAMSTER Jean-Lucien Rouleau, MD, FRCP(C); Leonard Chuck, PhD; Gabor Hollosi, PhD; Joan Wikman-Coffelt, PhD; Parris Kidd, PhD; William W. Parmley, MD, FACC, University of California, San Francisco, Ca.

Thirty-seven cardiomyopathic (CM) Syrian hamsters, strain UMX7, were injected from day 21 to 90. They were divided into five groups: saline (S), propranolol (P), digoxin (D), verapamil (V) and hydralazine (H). Mechanical studies were performed on their isolated papillary muscles, histologic studies were done on a strip of their left ventricular wall and the rest of the heart was used for actin activated myosin ATPase (AM ATPase) studies. These tests were also performed on 7 normal (C) hamsters.

N	Group	F (g/mm^2)	max/df/dt (g/sec)	Vmax (Lmax/sec)	AM ATPase (μmoles of Pi/mg/min)
7	C	2.5	35	2.7	0.211
9	S	1.6	24	2.0	0.135
7	P	1.6	25	1.9	0.136
7	D	1.2	18	1.5	0.129
7	V	3.0	38	2.8	0.164
7	H	2.2	28	2.4	0.163

Although all the CM groups had lower AM ATPase activities than the control hamsters ($p<0.05$), and none of the drugs could prevent the usual lesions from occurring, verapamil was able to preserve the intrinsic contractility (Vmax, force (F) and df/dt) of the remaining muscle ($p<0.05$). As well, hydralazine helped preserve contractility more than digoxin ($p<0.05$). We found a correlation between the Vmax and the AM ATPase ($R=0.60$), ($p<0.001$). By decreasing intracellular calcium we were able to help preserve the instrinsic contractile state and the AM ATPase activity of the remaining cells.

LIMITATIONS OF HISTOLOGICAL MORPHOMETRIC ANALYSIS IN PREDICTING DRUG PRESERVATION OF CONTRACTILITY IN CARDIOMYOPATHY. Parris Kidd, Ph.D.; Jean-Lucien Rouleau, M.D.; Thomas Yasumura, M.Sc.; Leonard H.S. Chuck, Ph.D.; William W. Parmley, M.D. Univ. of Calif, San Francisco.

Strain UM-X7.1 Syrian hamsters spontaneously develop a lethal cardiomyopathy. To correlate the effects of drugs on muscle damage and contractility, we injected saline, hydralazine, propranolol, digoxin, or verapamil into 30 hamsters from 7 litters twice daily, from days 21 through 90. The papillary muscle was used for mechanical measurements; a strip of LV wall was fixed in glutaraldehyde and embedded in GMA plastic for histology. 4-μm-thick sections cut from 3 levels were stained with Pb hematoxylin and 4 fields of each were examined at 960X under a 100-square counting grid. We measured % active lesions, % healing lesions, % calcifying lesions, and % hypercontracted areas, and from these derived the % undamaged muscle. Litter-to-litter variability limited statistical analysis, but definite trends were evident. None of the drugs prevented muscle damage completely. Partial prevention of muscle damage did not correlate with preservation of contractility (Rouleau et al., these proceedings). Verapamil, which partially prevented muscle damage (mean +SD, 88.9±4.2% vs 77.2±10.8% for controls, $P<0.1$) preserved contractility well (Vmax 2.8±0.5 vs. 2.0±0.5 for controls), but propranolol, which also prevented muscle damage (90.4±4.1%, $P<0.1$), preserved contractility poorly (Vmax 1.9±0.5); hydralazine, which partially preserved contractility, did not prevent muscle damage. However, the frequency of hypercontracted areas correlated inversely with the preservation of contractility by each drug (for developed force, $R=0.29$, $P<0.1$; for V max, $R=0.35$, $P<0.05$). Verapamil, which preserved contractility best, reduced hypercontracted areas strikingly (0.1±1.3% vs. 5.0±4.9% for controls).

TIME COURSE OF VULNERABILITY TO REPERFUSION-INDUCED VENTRICULAR FIBRILLATION. David A. Cox, Richard Verrier, Ph.D., F.A.C.C., Kenneth Baughman, M.D., Bernard Lown, M.D., F.A.C.C. and Stephen F. Vatner, M.D. From the Depts. of Med., Harvard Med. Sch., Peter Bent Brig. Hosp. and Harvard Sch. of Pub. Health, Boston, MA 02115

It has been well documented that acute coronary artery (CA) reperfusion following CA occlusion (O) is associated with reduced threshold to ventricular fibrillation (VF) and consequently, a high incidence of VF. It is not known how long after CAO that reperfusion will elicit increased susceptibility to VF, although reports have indicated this occurs with CA reperfusion 1 hr after CAO. In contrast, we have observed in 14 consecutive conscious dogs no instances of VF upon release of CAO after 1 hr. To examine the time course of susceptibility to VF, 15 additional dogs were instrumented with an hydraulic occluder and a single crystal CA Doppler flow probe to confirm CAO and reperfusion. One wk later, using chloralose anesthesia, VF thresholds were determined with a single 10 msec stimulus delivered through a transvenous bipolar catheter positioned in the apex of the right ventricle.

	VF THRESHOLD (MILLIAMPERES)		
	Pre-CAO	CAO	REPERFUSION
10' CAO (n=5)	22 ± 3 (Mean ± SE)	12 ± 2*	8 ± 2*
30' CAO (n=5)	23 ± 3	14 ± 3*	10 ± 3*
45' CAO (n=5)	21 ± 2	12 ± 1*	25 ± 4

* significantly different from pre-CAO, $p<0.05$.

Thus, as has been shown previously, VF threshold falls with CAO and falls further with release of CAO at 10 min. However, in contrast to what has been suspected, this phenomenon changes radically between CAO of 30 and 45 min. Interestingly, this reduction in susceptibility to VF is nearly coincident with the time course of irreversibility of cell death, which could be of importance in understanding the mechanism of this lethal arrhythmia.

DOES NIFEDIPINE PROTECT AGAINST REPERFUSION DAMAGE? Pieter D. Verdouw, Ph.D., Folkert J. ten Cate, MD, Hans M. Hartog, BS, Paul G. Hugenholtz, MD, FACC, The Thoraxcenter, Erasmus University, Rotterdam, The Netherlands.

Sudden reperfusion (R) of ischemic myocardium (Isch) may cause further disturbances in calcium metabolism, (so called) reperfusion arrhythmias and myocardial damage. Since Nifedipine (N) is a calcium antagonist, its efficacy during R was tested in 24 pigs in whom the left anterior coronary artery (LAD) flow was reduced to 22%. Before reduction (red) systolic wall thickening (swt) was 42 ± 3% of the end-diastolic thickness (edt). After red there was no systolic thickening. All animals were reperfused after 30 minutes of low flow. Eight animals served as controls (C), 8 received an infusion of 2 $\mu g/kg^{-1}$ (L) and 8 an infusion of 15 $\mu g/kg^{-1}$ of N (H), from 10 min. prior to R until 5 min. of R. During red, the overall hemodynamic effects of H were slight, but systemic vascular resistance declined by 20% and left ventricular end-diastolic pressure by 16%. With H regional myocardial flow, measured by microspheres, to the ischemic zone increased from 22 to 36% ($p<0.05$) without an improvement in swt. Flow to the control zone increased by 20% ± 6% ($p<0.05$) without change in swt. During subsequent R, swt recovered to only 20 ± 2% of edt for L and C, but increased to 35 ± 3% (80% of C value) for H ($p<0.05$). Moreover during R, severe ventricular ectopics were observed in all C, but in only 1 H. We conclude that timely administration of N before and during R will prevent severe ventricular rhythm disturbances and enhance recovery of regional myocardial function.

ECHOCARDIOGRAPHY: VENTRICULAR FUNCTION II
10:30-12:00

QUANTITATIVE DOPPLER FLOW ESTIMATORS: IMPROVED CHARACTERIZATION AND SEPARATION OF NORMAL FROM ABNORMAL FLOW. Larry Miller, PhD; William J. Bommer, MD, FACC; Dean T. Mason, MD, FACC; Anthony DeMaria, MD, FACC; University of California, Davis, California.

The detection of abnormally disturbed flow in previous pulse Doppler studies has been limited by M-mode imaging, noisy receivers, gain dependent output displays, and high velocity aliasing. Thus, we built a high-gain low-noise Doppler detector and a hi-fidelity microprocessor-based spectral analyzer (fast Fourier transform) and added it to a 2D-echo Doppler instrument for accurate positioning of the sample volume. This system features improved signal-to-noise ratios (20db better than commercial units); the ability to avoid high-velocity aliasing with unidirectional flow; and gain independent spectral displays with high velocity resolution (43 Hz), high time resolution (12ms), and a 32-level grey scale. Using the median absolute deviation (MAD) of the Doppler frequency as a measure of the velocity distribution spread in blood, we evaluated blood flow patterns in 10 normal subjects. The Doppler MAD in normals ranged from 400-860 Hz aorta, 220-770 Hz right atrium, 130-690 Hz right ventricle, 180-860 Hz pulmonary artery, 270-900 Hz left atrium and 130-860 Hz left ventricle. These flow patterns and MAD's differed significantly from the abnormal flow patterns and MAD's (900-2000 Hz) ($p<.01$) seen in 30 patients with mitral stenosis (5), aortic stenosis (8), mitral regurgitation (10) and aortic regurgitation (10). Thus, improved Doppler systems can eliminate many of the prior limitations of the technique and yield detailed hard copy print outs of cardiac flow patterns. The analysis of these flow patterns yields quantitative statistical parameters which can be used to objectively distinguish normal flow from abnormally disturbed flow.

ROLE OF TWO-DIMENSIONAL ECHOCARDIOGRAPHY IN EVALUATION OF PATIENTS WITH POST MYOCARDIAL INFARCTION VENTRICULAR SEPTAL DEFECT
Harry L. Bishop, MD; Robert S. Gibson, MD; George A. Beller, MD, FACC; Randolph P. Martin, MD, University of Virginia, Charlottesville, Va.

In patients (pts) with suspected ventricular septal defect (VSD) following MI, bedside hemodynamics may not permit the definitive diagnosis and cannot assess LV wall motion. Two-dimensional echocardiography (2DE) may allow the noninvasive diagnosis and localization of a post-MI VSD and provide an assessment of overall LV function. In 7 pts with a recent MI, VSDs were detected by 2DE and localized to the inferior septum in 3 and anterior septum in 4. All VSDs were confirmed by catheterization, surgery, and/or post-mortem exam. The subcostal and apical 4-chamber views with anterior and posterior transducer angulation were the optimal views. A septal aneurysm was detected in all pts. In 5 of 5 pts, a negative contrast effect was seen in the RV after the IV injection of saline. To assess global and segmental LV function, a LV wall motion index (WMI) was calculated using an 11 segment analysis (-1 hyperkinetic, 0 normal, +1 hypokinetic, +2 akinetic, +3 dyskinetic; WMI=total score/number of segments analyzed). Of 77 possible segments, 75 were interpretable. The WMI in the 4 survivors (mean 0.77 ± .41) was lower than in the 3 nonsurvivors (mean 1.66 ± .24; $p<.021$). There was no difference in the mean age, peak creatine kinase, VSD location, or Killip class. Monitoring of LV function by 2DE aided in guiding the timing of angiography and surgery in 5 pts. In the remaining 2 pts the detection of marked LV dysfunction by 2DE was instrumental in the decision for no further invasive studies or surgery. 2DE permits the noninvasive diagnosis and localization of post-MI VSD, provides prognostic information, and aids in management decisions.

THE EFFECT OF ALCOHOL ON LEFT VENTRICULAR RELAXATION IN CORONARY ARTERY DISEASE: ECHOCARDIOGRAPHIC ASSESSMENT BY COMPUTER ASSISTED ANALYSIS OF LEFT VENTRICULAR WALL VELOCITY.

John S. Gottdiener, MD; Lucy Van Voorhees, MD; Judy Gay; Robert DiBianco, MD,FACC; Dan L. Maloney, MSEE; Ross D. Fletcher, MD,FACC. Veterans Administration & Georgetown University Medical Centers, Washington, D.C.

Although ethyl alcohol may have adverse effects on systolic left ventricular (LV) function, its effects on diastolic LV function in patients with coronary artery disease (CAD) are uncertain. In order to determine the effects of alcohol on diastolic LV function, echocardiograms (echo) were done in 12 pts with CAD before and after 180 ml of 40% alcohol given p.o. over a 1 hour period. The septal endocardial surfaces and endo and epicardial surfaces of the LV posterior wall were digitized at 3 msec intervals in 7 pts with high-quality echos using a tablet digitizer and dedicated microcomputer. After alcohol (av plasma level 99±4 SEM mg%) the av peak LV diastolic filling rate, normalized by the instantaneous LV internal dimension, decreased from 3.0±0.5 sec^{-1} to 1.8±0.1 sec^{-1} ($p<0.03$). Decreases which were not statistically significant occurred in av normalized peak rates of diastolic thinning of the septum (before alcohol 2.7±0.4 sec^{-1}, after alcohol 2.5±0.3 sec^{-1}) and LV posterior wall (before alcohol 4.5±0.8 sec^{-1}, after alcohol 3.5±1.3 sec^{-1}). Parameters of systolic function, i.e. fractional shortening, mean Vcf, normalized peak rates of septal and posterior wall thickening, and peak Vcf were unchanged by alcohol.

Hence, alcohol may impair LV diastolic filling even without depression of LV systolic function. Alcohol should be used with caution in CAD pts prone to pulmonary congestion.

DIFFERENTIATION OF CONSTRICTIVE PERICARDITIS AND RESTRICTIVE CARDIOMYOPATHY BY ECHOCARDIOGRAPHY

Richard A. Meyer, M.D., FACC, Gregory G. Janos, M.D., A. Kalavathy, Peter Engle, M.D., Samuel Kaplan, M.D., FACC, Children's Hospital Medical Center, Cincinnati, Ohio.

Constrictive pericarditis (CP) and restrictive cardiomyopathy (RC) may be indistinguishable clinically and hemodynamically. Computer analysis of digitized M-mode echo was used to study left ventricular (LV) diastolic function in four patients with CP, three with RC and 40 normal controls (C). The echoes were digitized by an on-line mini computer and measurements were taken from the printouts of the plotted contour of the LV chamber and posterior wall (LVPW). Values found normally to be related to heart rate were corrected by regression equation and presented as % of normal. The results are as follows:

	Normalized Rates (mean± SD sec^{-1})		Intervals (mean± SD)		
PT	Max. Filling LV	Max. Thin LVPW	Major Filling LV+	Total Thin LVPW+	Min. Dim. to Max. Fill LV (sec)
C	3.2 ± 0.8	-6.3 ± 1.5	-	-	0.08 ± 0.02
RC	2.3 ± 1.0*	-2.3 ± 1.1*	129 ± 4	142 ± 29*	0.11± 0.03*
CP	3.9 ± 1.2♣	-3.9 ± 1.6*♣	79 ± 9♣	163 ± 18*	0.05± 0.01*♣

* = versus control, ♣ = versus RC at $p < .05$; + = % normal

Diastolic function of the LV is abnormal in both RC and CP; however, the rate and duration of filling as well as LVPW pattern of relaxation are charcteristic for each group and appears to permit separation of RC from CP. Therefore, digitized echo may prove useful in differentiating these two conditions which frequently produce diagnostic dilemmas because they have similar clinical and hemodynamic features.

DIAGNOSIS OF PACING CATHETER PERFORATION BY REAL TIME TWO-DIMENSIONAL ECHOCARDIOGRAPHY

Bapineedu Gondi, MD, Navin C. Nanda, MD, FACC, University of Rochester Medical Center, Rochester, NY

Myocardial wall perforation produced by RV temporary transvenous pacing catheters (PCs) was identified in 5 patients (pts) by real time two-dimensional echocardiography (ATL 90° scanner). In 3 pts with loss of sensing and/or increased pacing threshold, the PCs which presented as dense, linear echoes with posterior reverberations could be seen passing through the RV apex with the tip located 2mm - 1cm outside the cardiac border. Perforation was not suspected on chest X-rays or 12-lead pacing ECGs. Pericardial effusion developed in 2 of 3 pts (1 localized, 1 generalized) but did not increase in size and was not associated with cardiac tamponade. In 1 pt PC was repositioned under echo control in another area of the RV apex with marked decrease in pacing threshold. In the 4th pt, the catheter was seen to extend through the atrioventricular septum into the LV and the tip was in contact with the posterior wall. In the 5th pt the catheter had partially penetrated the ventricular septum near the apex without entering the LV cavity. Both these pts showed right bundle branch block patterns on the pacing ECGs and chest X-rays showed PC malposition without pinpointing the exact location. In 4 of 5 pts the identification and abnormal location of the PC was confirmed during PC withdrawal when the movements of the PC could be seen to correspond with manual manipulations. Withdrawal intracardiac electrograms were done in the 5th pt and in 1 pt with RV apical perforation and showed changes typical of perforation. Autopsy verification of perforation was available in 2 pts including 1 pt in whom the RV apical PC was not withdrawn. In conclusion, two-dimensional echocardiography is a useful, non-invasive, non-ionizing tool which provides direct evidence for PC perforation.

SUPERIORITY OF THE AMERICAN SOCIETY OF ECHOCARDIOGRAPHY CRITERIA FOR MEASURING WALL THICKNESS BY TWO-DIMENSIONAL ECHOCARDIOGRAPHY

Michael J. Barrett, MD; Larry Jacobs; Jonathan Gomberg; Lynn Horton; Robert Leyrer; Theodore Krouse, MD; Steven G. Meister, MD,FACC, Medical College of Pennsylvania, Philadelphia, Penna.

Three conventions have been proposed for measuring wall thickness (WT) of the left ventricle by echocardiography: Convention 1 = leading edge to trailing edge (traditional), convention 2 = trailing edge to leading edge (Penn), and convention 3 = leading edge to leading edge (American) Society of Echocardiography)(ASE). No direct comparison of these conventions with anatomic WT and cavity area (A) has been performed using 2-dimensional echo (2D Echo). Therefore, we tested each convention in 11 phantom heart tomograms, using a phased array system. Circular phantoms were constructed from 1cm strips of fresh, unfixed sharply-cut bovine muscle. Anatomic WT and A were measured directly with an XY plotter. Phantoms were then immersed in a water bath and 2D Echo images recorded. Eighty wall segments were measured by each convention:

Method	M±sem	% error	t-test
Anatomic WT	11.0mm±.02	-----	-----
Convention 1	16.0mm±.02	46%±1.0	p<.001
Convention 2	8.4mm±.02	24%±2.0	p<.001
Convention 3	12.0mm±.02	16%±1.2	p=ns

Results of cavity area were similar. Convention 1 underestimated A by 25%±3.6 (p<.001). Convention 2 overestimated A by 19%±3.1, p<.01) and convention 3 underestimated A by 12%±2.5 (p=ns).

Conclusion: The leading edge to leading edge convention recommended by ASE is more accurate than other conventions for measuring wall thickness and cavity area by 2D echo when compared to anatomic measurements.

from Raven Press

A Major Journal:

Journal of Cardiovascular Pharmacology

Editors-in-Chief: Leon I. Goldberg and Jan Koch-Weser

The **Journal of Cardiovascular Pharmacology** brings together new information about cardiovascular drugs from researchers who develop and evaluate these drugs and clinicians who use them in therapy. The journal publishes original or review articles on the creation, development, and evaluation of such drugs and on their mechanism of action, therapeutic effectiveness, metabolism, side effects, and interactions.

Volume 3 (1981). Bimonthly. Personal Subscription rates: U.S. $53.00; elsewhere $65.00
Library and Institutional rates: U.S. $68.00; elsewhere $80.00

Two Important Series:

Atherosclerosis Reviews

Series Editors: R. Paoletti and A. M. Gotto, Jr.

This series reviews the most recent advances in our understanding of the causes, prevention, and treatment of atherosclerosis. It emphasizes research findings of the greatest potential clinical applicability, and will be of interest to all clinicians and biologists dealing with atherosclerosis and its complications.

Volume 8: Prostaglandins and Cardiovascular Disease

Editor: R. J. Hegyeli

This volume reviews our understanding of the role of prostaglandins in the normal functioning of the cardiovascular system, in a variety of pathological conditions, and in medical management of these conditions. Topics include the role of prostaglandins in the control of blood pressure, platelet aggregation, and cyclic AMP levels in the heart; the pharmacology of prostaglandins and their derivatives; the relationship of diet and smoking to prostaglandins; and current methodologies for conducting research on prostaglandins and cardiovascular disease. **220 pp., $25.00 (1981) ISBN 0-89004-516-X**

Volume 7: Measurement and Control of Cardiovascular Risk Factors

Editor: R. J. Hegyeli

This volume focuses on the control of cardiovascular disease by environmental modification. Chapters discuss the epidemiology of coronary artery disease, the major predisposing factors, the role of smoking and diet in its development, drug treatment of primary hyperlipidemias, and the role of vasospasm and other modulatory factors. **352 pp., $36.50 (1980) ISBN 0-89004-396-5**

Perspectives in Cardiovascular Research

Series Editor: A. M. Katz

This series explores research issues of central importance to our understanding of the normal and pathological functioning of the cardiovascular system. Volumes in this series provide multidisciplinary reviews of topics such as developmental and physiological correlates of cardiac muscle, neural mechanisms in cardiac arrhythmias, ischemic myocardium and antianginal drugs, epidemiology and prevention of hypertensive diseases, and mechanisms of cardiac morphogenesis and teratogenesis.

Volume 5: Mechanisms of Cardiac Morphogenesis and Teratogenesis

Editor: T. Pexieder

This volume presents a multidisciplinary analysis of the cellular and subcellular mechanisms regulating cardiac morphogenesis and teratogenesis in the embryo. Sections cover organogenesis of the heart; cell proliferation; cell death; extracellular matrix; cell surface; heart cell physiology and interactions; genetic control; and epigenetic control of cardiac morphogenesis. Each section includes findings from both human and animal studies, particularly on the rat and chick embryo.
528 pp., 251 figures, $48.00 (1981) ISBN 0-89004-460-0

Volume 4: Prophylactic Approach to Hypertensive Diseases

Editors: Y. Yamori, W. Lovenberg, and E. D. Freis

"Offers a wealth of papers from experienced investigators in the area of hypertension; they cover the wide spectrum of treatment, prevention, cause, and basic laboratory investigations. . . .Commands the attention of every physician who is deeply or even tangentially interested in hypertension and its long-term effects and implications."— Mayo Clinic Proceedings **624 pp., $58.50 (1979) ISBN 0-89004-339-6**

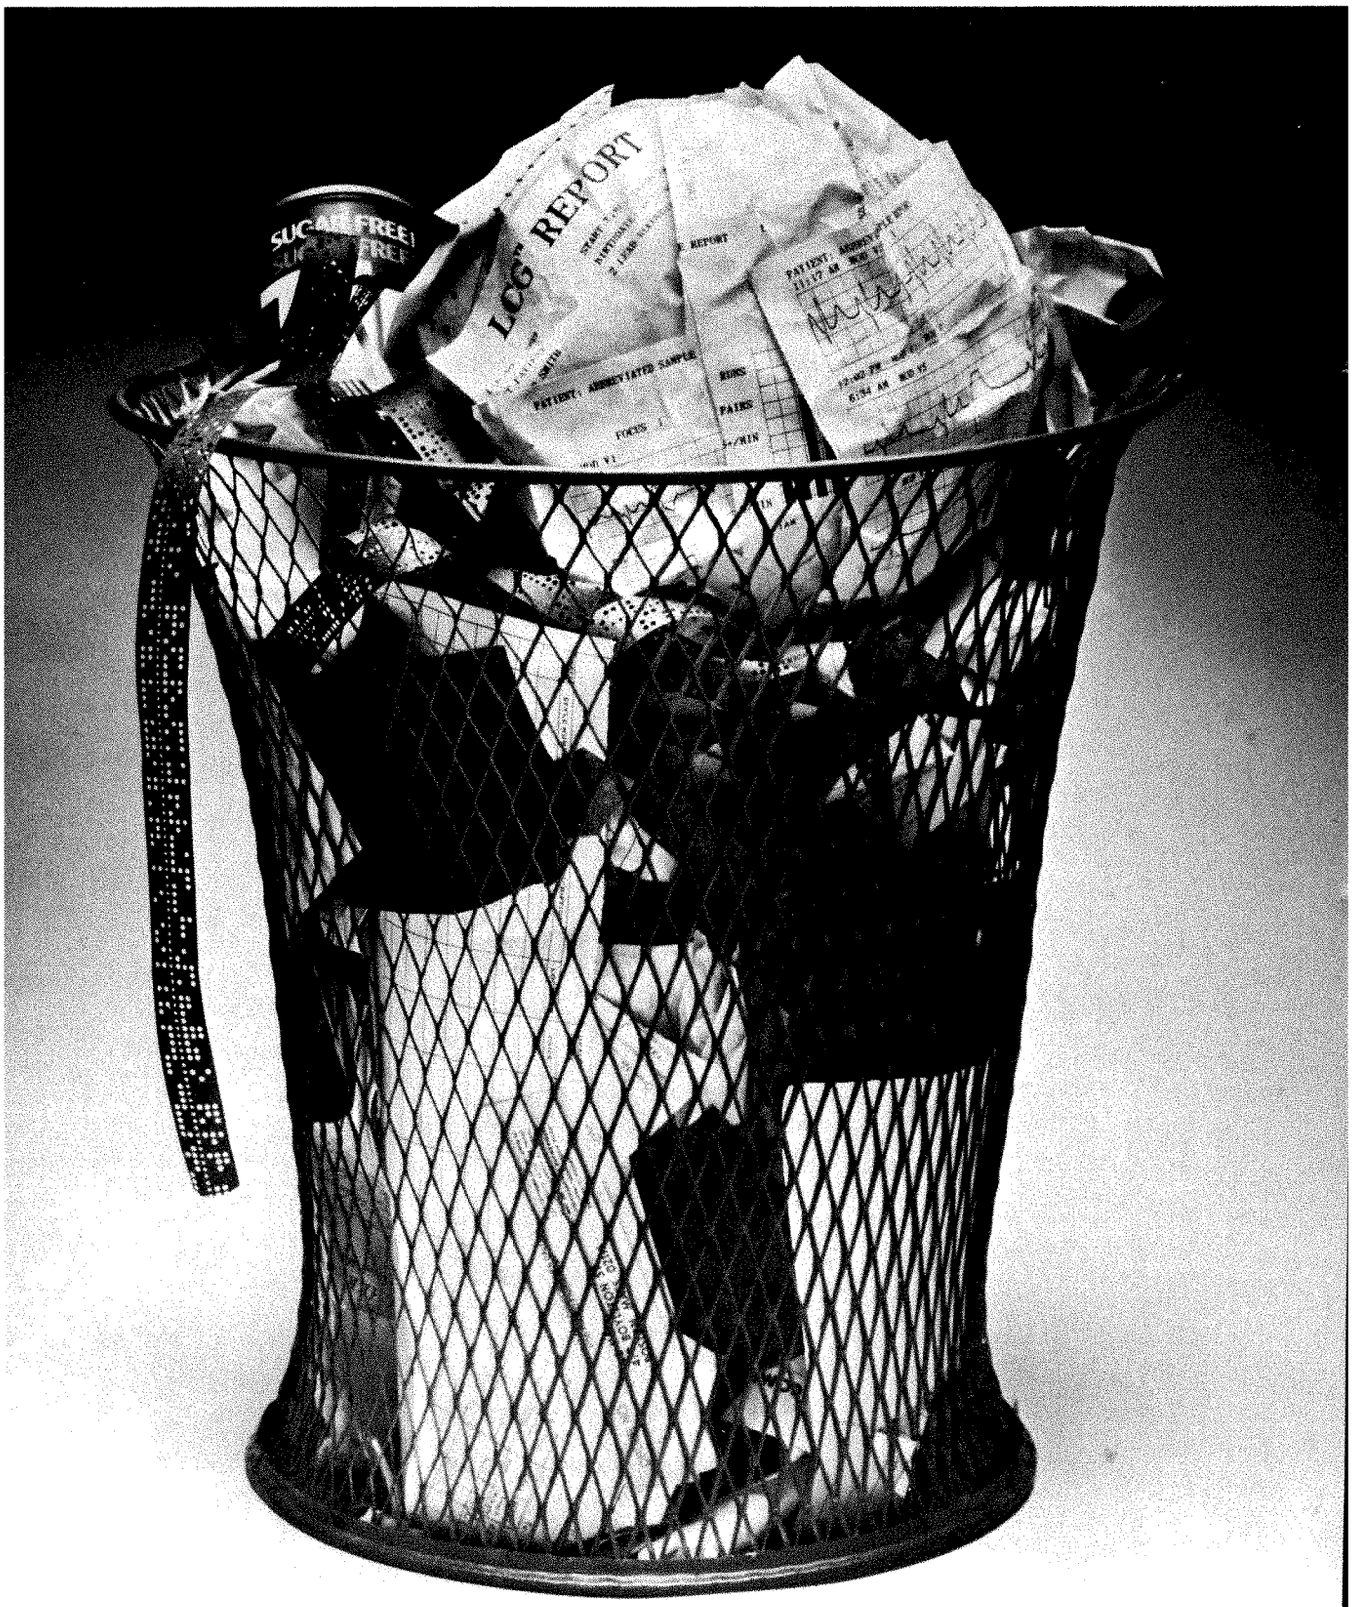
At Clinical Data, we asked ourselves... What should we do with the world's most accurate and readable long-term ECG report?"

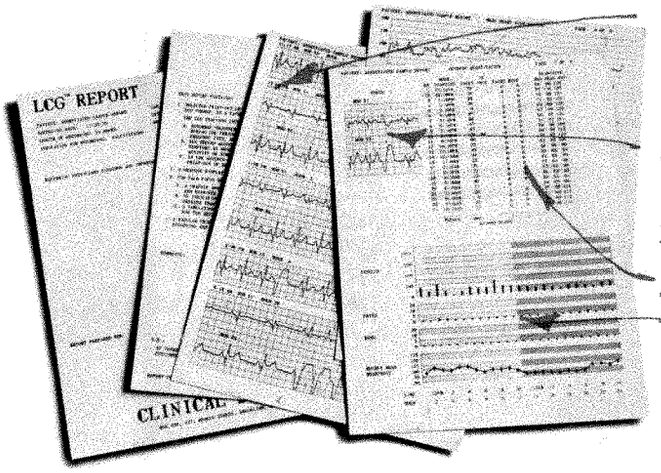


Introducing an even more accurate and readable LCG™ Report.

That's the trouble with being number one... you're never satisfied. And that's why, if you subscribe to Clinical Data's long-term ECG (Holter) recording service, *you* always will be satisfied.

Because *we* do all the worrying. All the research. All the up-dating to the latest technology. And all the "back to the drawing boards" redesigning of the reporting format that has become the state of the art—in a super competitive field.

Our latest format features several new presentations of ectopic data.



It not only gives you more data, but it also makes that data easier to find and understand. The result? Easier interpretation and a more confident diagnosis.

It's the end result of doing everything right.

The right recording technique, with a one pound, 24-hour, continuous, two-lead FM cassette recorder with a crystal controlled timing track.

The right reviewing technique, with Clinical Data's exclusive Stein/Peterson™ Examination Technique which introduced stationary ECG presentations to Holter recording.

And the right reporting technique, with *no* data compression. With ECG strips, hourly heart rate, graphic and numerical quantitation of up to eight different ectopic foci validated by the examiner.

You get the picture? Even if you've seen one of Clinical Data's LCG reports, you really haven't seen one of Clinical Data's *new* LCG reports. We've made the best even better. Call or write. We'll send you one.

CARDIOLOGY UPDATE, 1981: Reviews for Physicians

Elliot Rapaport, M.D., Editor-in-Chief, Professor of Medicine, University of California, San Francisco, Cardiology Service, San Francisco General Hospital, San Francisco, California.

The latest volume in the acclaimed *Cardiology Update* series, the 1981 edition contains important new subject matter of current interest to cardiologists, internists, cardiovascular surgeons, house officers and students. Topics include: new developments in phonocardiography, emissive tomography, computerized interpretations of electrocardiograms, the management of hypertension, and clinical experience with the newer antiarrhythmic agents.

1981 392 pages Cloth $29.95

(Available outside North America from Churchill-Livingstone, Ltd.)

Also edited by Dr. Rapaport...

CARDIOLOGY UPDATE, 1979: Reviews for Physicians

This volume broke new ground by making available in book format state-of-the-art developments in cardiology. "...an excellent reference for generalists and housestaff and for individuals needing ready access to information...particularly clear illustrations of frequently encountered conditions...The editors chose acknowledged experts to write...lucid...informative...." *The Annals of Thoracic Surgery*

1979 364 pages Cloth $26.95

The first volume in a major new series!

CARDIOVASCULAR AND RESPIRATORY DISEASE THERAPY

(Clinically Important Adverse Drug Interactions, Vol. 1) **J.C. Petrie, Editor**

This volume provides an authoritative evaluation, based on pharmacological principles, of the clinically significant adverse interactions associated with drugs used in the treatment of cardiovascular and respiratory diseases. Drug response is evaluated in light of many significant patient factors (hepatic, renal, cardiovascular dysfunction) which critically affect therapy.

1980 352 pages Cloth $40.00*

The definitive book on circulation physiology...

FUNDAMENTAL PRINCIPLES OF CIRCULATION PHYSIOLOGY FOR PHYSICIANS

By **Hiroshi Kuida, M.D.,** Professor of Medicine and Physiology, University of Utah College and Medicine, Salt Lake City, Utah

"...a clear presentation of a central area of physiology...provides brief and understandable summaries of fundamental principles of circulation physiology...easy to read...illustrations clarify the text...recommended." *JAMA*

"...a pleasure to read...The purpose is always to promote the background physiology and the reason for its importance to the functioning whole...some of the most clarifying explanations I have ever encountered..." *The New England Journal of Medicine*

Now The European Journal of Cardiology becomes...

THE INTERNATIONAL JOURNAL OF CARDIOLOGY

Editor-in-Chief: John A. Kastor, M.D., Professor of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania—plus an outstanding editorial board drawn from the international community of cardiologists.

Already hailed as one of the world's most prestigious cardiology journals, **The European Journal of Cardiology** is now changing its name to better reflect its broad international scope and quality. Now called **The International Journal of Cardiology,** it will continue to publish the best and most significant basic and clinical research being done today—and to provide practicing clinicians and researchers with an authoritative forum for worldwide progress in their field.

To mark this significant development in the journal's history, the publishers are pleased to announce the introduction of a *personal subscription rate*, bringing **The International Journal of Cardiology** within easy reach of individual subscribers.

Subscription Rates Including Postage: Personal Rate: $38.00/Dfl. 74.00, Institutions: $93.75/Dfl. 183.00., (1981, 1 Volume in 6 Issues)

HOW TO MAKE STRESS TESTING A ONE-PERSON OPERATION.

HIRE ANTHRO-METRICS CC-101

Introducing the stress test system that only takes one person to operate: Anthro-metrics CC-101.

Now stress tests can be administered by the doctor. Or by a technician. Either way, the CC-101 delivers improved data accuracy and lower cost per patient than ever before possible.

Printed Test Reports

With the CC-101, there's no time lost taking notes. Or typing them. Because at the end of the test, it automatically summarizes test data for the doctor to review. A printed report provides a complete analysis for the patient's file in a standard 8½" x 11" format.

Improved Accuracy

The CC-101 virtually eliminates artifacts and outside electrical interference. There is automatic time correlation between blood pressure readings, heart rate, S-T segment and test stage. And the CC-101's advanced microprocessor control sets industry standards for accuracy.

Lower Cost per Patient

Anthro-metrics provides physicians with more useful data for less. Less training time. Less time to set the machine before tests. Less personnel to conduct the tests. Even less expensive supply costs.

So you get more tests. For less cost per patient.

Put ANTHRO-METRICS CC-101 to work for you.

CORONARY ARTERY DISEASE: MEDICAL THERAPY
10:30-12:00

EXACERBATION OF ISCHEMIA IN VASOTONIC ANGINA PECTORIS BY PROPRANOLOL. Rose M. Robertson, MD, FACC; Alastair J.J. Wood, MD; Yvonne Bernard, RN; David Robertson, MD, Vanderbilt University Medical Center, Nashville, TN.

Propranolol (P) has been reported to improve vasotonic angina (VA), a syndrome characterized by chronic recurrent episodes of ischemia due to coronary artery spasm. We performed 7 double-blind, placebo(PLA)-controlled trials of P in 6 patients (pts) with VA (ages 51-72, 3 male, 3 female). Coronary anatomy ranged from normal to 70% stenosed. Continuous ECG monitoring was used to document ischemic episodes. Both low-dose (LD) P (40 mg po q6h) and high-dose (HD) P (160 mg po q6h) were used. Serum levels were obtained in four pts (mean=52, range 28-74 ng/ml on LD-P; mean=280, range 222-342 ng/ml on HD-P). Ischemic episodes on PLA were compared to those on P and to those during a PLA period after P washout.

	MEAN LENGTH OF EPISODES(min)				TOTAL TIME ISCHEMIC/DAY(min)			
Trial	PLA	LD-P	HD-P	PLA	PLA	LD-P	HD-P	PLA
1	0.0	4.1	9.1	0.0	0.0	4.1	9.1	0.0
2	2.4	3.9	6.1	0.0	2.4	23.4	48.8	0.0
3	1.9	-	4.5	1.1	34.2	-	76.2	13.9
4	0.6	0.5	0.7	0.5	16.6	19.5	21.0	12.0
5	2.0	4.8	5.2	1.3	18.7	38.4	91.7	8.3
6	1.3	3.4	3.7	1.9	13.4	27.2	25.9	15.8
7	5.4	6.5	6.2	4.5	178.2	116.8	155.0	115.0
mean	1.3	3.1*	3.4*	1.3	37.6	38.2	61.1*	23.6

* = $p<0.05$

With P all pts increased either the length or frequency of ischemic episodes, or both. Four of 5 additional VA pts had an increase in angina on P by history. Thus, P was detrimental in 9 of 11 pts with VA, unrelated to underlying coronary anatomy. No patient was significantly improved. Propranolol should be avoided in patients with chronic recurrent coronary artery spasm.

DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED COMPARISON OF PROPRANOLOL AND VERAPAMIL IN PATIENTS WITH STABLE, EXERTIONAL ANGINA PECTORIS. SM Johnson, MD, DR Mauritson, MD, J Corbett, MD, JT Willerson, MD, FACC, LD Hillis, MD, FACC, U of Texas Health Science Center, Dallas, TX.

This study was performed to compare the relative efficacies of propranolol (P) and verapamil (V) in patients with stable, exertional angina (A). In 18 patients (16 men, 2 women, mean age 58 yrs) with coronary artery disease and A, low (40mgq6h) and high (80mgq6h) doses of P were compared to low (80mgq6h) and high (120mgq6h) doses of V in a double-blind, randomized, placebo(Pl)-controlled study lasting 7½ weeks (wks): 2 wks Pl "run-in," 2 wks P or V (1 wk low dose, 1 wk high dose), 1½ wks Pl "wash-out," and 2 wks P or V (1 wk low dose, 1 wk high dose). During each period the following were quantitated: (1)chest pains/wk, (2)nitroglycerin (NTG) used/wk, (3) transient ischemic ST segment deviations (STD) on 2 channel Holter monitoring, and (4)response to supine bicycle exercise, including ECG analyses and an assessment of LV volumes and ejection fraction (EF) by equilibrium gated blood pool scintigraphy. The 2 Pl periods were similar.

	A/wk	NTG/wk	STD/day	Rest-EF	Exercise-EF
Pl	6.6±9.7	10.0±15.4	2.2±2.9	57±16	53±18
Hi-P	3.1±7.6*	5.4±13.7	1.2±1.9	60±16	57±16*
Hi-V	1.7±2.7*	2.4±3.9*	0.6±1.2*	54±14	50±14

(All figures are mean±SD; * $p<0.05$ when compared to Pl.)

Hi-P and Hi-V were similarly efficacious in the relief of A. NTG use and the incidence of STD were lowest with Hi-V. LVEF during rest and exercise was slightly higher during Hi-P than during Hi-V. Thus, in a double-blind, randomized study of patients with stable angina, (1)propranolol and verapamil are of similar efficacy in the relief of angina, and (2)neither agent induces important LV depression. Verapamil is a suitable and effective alternative to propranolol in the patient with stable angina.

ORAL VERAPAMIL VS PROPRANOLOL IN CORONARY ARTERY DISEASE: EVALUATION OF LEFT VENTRICULAR FUNCTION BY EXERCISE RADIONUCLIDE VENTRICULOGRAPHY. Martin A. Josephson MD, Harvey S. Hecht MD, FACC, James M. Hopkins BS, and Bramah N. Singh MD, PhD, FACC. Wadsworth VA Medical Center and University of California, Los Angeles, California.

Although the antianginal actions of verapamil (V) are known, the effects of chronic V therapy on exercise left ventricular ejection fraction and exercise induced regional wall motion abnormalities (RWMA) in patients (pts) with coronary artery disease (CAD) and its effects compared to propranolol (P) are unclear. Therefore, 18 pts with CAD underwent supine multistage bicycle exercise during placebo control (C), V 120 mg and P 80 mg qid treatment according to a randomized single blind crossover design. EF and exercise induced RWMA were determined by equilibrium radionuclide blood pool imaging. 4 of 18 pts had a normal exercise response, i.e. > .05 increase in EF and no exercise induced RWMA. 14 pts had an abnormal exercise response and EF, RWMA, heart rate (HR), and systolic blood pressure (BP) at the same maximal workload are shown for this group of pts. Results are shown as mean ± standard deviation.

		EF	RWMA	HR	BP
REST	C	.53±.11		67±13	130±15
MAXIMUM EXERCISE	C	.46±.11	17	124±18	165±21
	V	.50±.12*	7*	113±16**	160±21
	P	.50±.12*	12	91±10**	143±14**

(*$p<.05$, **$p<.01$ compared to control exercise)

Conclusions: 1) Both V and P decrease the extent of exercise induced reduction in EF in CAD pts. 2) V decreases the number of exercise induced RWMA, 3) maximal exercise HR is decreased by both V and P; only P reduces BP at maximal exercise.

PROGNOSIS OF VARIANT ANGINA PATIENTS TREATED WITH CALCIUM ANTAGONIST DRUGS

David D. Waters, MD, FACC; Jadwiga Szlachcic, MD; Pierre Théroux, MD, FACC, Montreal Heart Institute, Montreal, Que

Following hospital discharge 100 consecutive variant angina (VA) pts were followed for 17.6 (range 1-60) months. Each had exhibited rest angina with transient ST elevation relieved by nitroglycerin. Mean age was 51.4 (range 26-70) years; 67 were men. ST elevation was anterior in 52, inferior in 46 and both simultaneously in 2. One, 2 and 3 vessel disease were present in 40, 12 and 2 pts; 44 had no stenosis >70%; 2 did not undergo arteriography.

Perhexiline was the only calcium antagonist available to treat the first 25 pts; 16 became asymptomatic, 3 had only effort angina, VA persisted in 4 and 2 developed MI. Of 24 pts treated with nifedipine 21 were asymptomatic, 1 had effort angina and VA persisted in 2. Of 12 treated with diltiazem, 11 were asymptomatic and VA continued in 1. Of 14 treated with verapamil, 13 were angina-free and 1 had VA. Thirteen pts were discharged on both nifedipine and diltiazem: 7 were asymptomatic, 1 had effort angina and 5 had VA. Of 9 pts treated with oral nitrates alone, 5 were asymptomatic, 1 had effort angina and 3 developed MI. Bypass surgery was initial treatment in 3 and was done later in 6 others. Calcium antagonists were discontinued in 28 asymptomatic pts. VA recurred in only 4 but within 2 weeks 2 others developed MI. Overall 4 pts died, all within 12 months, 1 with MI, 1 by suicide and 2 suddenly, 1 with normal arteries taking perhexiline and 1 off drug after bypass surgery. MI occurred in 7 others, within 3 months in 6. Two of these 7 had no stenosis >50%. MI or cardiac death did not occur in any pt while taking nifedipine, diltiazem or verapamil.

We conclude that prognosis in VA improves after the initial phase of the disease. MI and death are not limited to pts with fixed lesions. Nifedipine, diltiazem and verapamil appear to be equally effective treatment.

BENEFICIAL EFFECTS OF DILTIAZEM ON EXERCISE PERFORMANCE IN PATIENTS WITH CORONARY ARTERY DISEASE AND ANGINA PECTORIS

Mark R. Starling, MD; Michael H. Crawford, MD, FACC; Robert A. O'Rourke, MD, FACC, University of Texas Health Science Center and Veterans Administration Hospital, San Antonio, Texas.

Diltiazem, a new slow-channel Ca++ blocking agent, has potential value in the treatment of patients (pts) with angina pectoris principally because of its vasodilator action on coronary and systemic arteries. Accordingly, we studied 10 pts with fixed coronary artery disease who had reproducible chest pain and $\geq$1 mm of ST-segment depression (ST↓) on treadmill exercise testing performed before and after one week control period of single-blind placebo administration. Subsequently, over a six week period, diltiazem (30 mg) or placebo was administered during sequential weeks in a randomized double-blind crossover fashion as one tablet QID, two tablets TID and two tablets QID for a total diltiazem dose of 120, 180 and 240 mg/day, respectively. Treadmill exercise was performed at the end of each week. Diltiazem at 120 and 180 mg/day did not alter exercise performance as compared to placebo. However, diltiazem 240 mg/day significantly increased time to angina by 1.9 min ($p<.05$), time to ST↓ by 2.2 min ($p = .01$), time to maximal exercise by 2.4 min ($p<.02$), and heart rate at maximal exercise by 14 beats/min ($p<.05$) without effecting the maximal heart rate-systolic blood pressure product compared to placebo values. In addition, two pts no longer had angina and two different pts did not develop ST↓ during treadmill exercise testing at the 240 mg/day dose. During the entire study, no adverse reactions were reported. We conclude that 240 mg of diltiazem a day significantly improves exercise performance in pts with angina pectoris due to fixed coronary artery disease and adverse side effects, rarely, if ever, occur at this dosage.

THE THERAPEUTIC AND ECONOMIC IMPACT OF NORMAL CORONARY ARTERIOGRAMS IN PATIENTS WITH SEVERE CHEST PAIN

David P. Faxon, MD, FACC; Doreen E. Kriegel, BS; Carolyn H. McCabe, BS; Thomas J. Ryan, MD, FACC, Boston University Medical Center, Boston, MA

A significant number of patients (pts) with severe angina (A) or intractable atypical pain (AP) referred for coronary arteriography (CA) are found to have normal vessels (NV). To determine what therapeutic or economic benefit may be derived from these studies we analyzed the data of 72 consecutive pts with NV (42 males, 30 females) followed for two years. The initial diagnosis was A in 46 and AP in 26. The mean age for A pts (45 years) differed from AP pts (49 years, $p<0.05$). Comparing the two year period prior to and following CA, the average number of hospital days/pt declined from 14.6 to 3.9 days ($p<0.005$) while the average number of hospital admissions/pt declined from 1.4 to 0.4 ($p<0.005$). This resulted in a decrease in estimated hospital costs/pt from $7300 to $1950 ($p<0.005$). Following CA, 33 of 42 (79%) A pts were reclassified as AP by their physicians ($p<0.001$). The number of pts taking Inderal before vs. after CA was reduced significantly (47/72 vs 26/72, $p<0.05$). Likewise the number of pts taking nitrates fell (57/72 vs 30/72, $p<0.05$). Employment status was not effected in this analysis. Results from a patient questionnaire indicated improvement in functional status following CA in 66% of pts.

We conclude, in pts referred for CA with severe chest pain complaints, the documentation of NV by CA not only alters the clinical assessment of symptoms; improves functional status and modifies medical therapy but also reduces hospitalization and subsequent medical cost. These therapeutic and economic benefits deserve consideration in any evaluation of CA for its overall effectiveness.

Q WAVES AND TRANSMURAL INFARCTS: THE TERMS ARE NOT THE SAME

RE Ideker, GS Wagner, KA Reimer, DR Alonso, SP Bishop, CM Bloor, JT Fallon, GJ Gottlieb, DB Hackel, HR Phillips, SF Roark, WJ Rogers, WK Ruth, RM Savage, RH Selvester, RM Ward, Duke Hosp., Durham, NC, U. Ala. Med. Ctr., Birmingham, Ala., UCSD Sch. of Med., LaJolla, CA, Mass. Gen. Hosp., Boston, MA, Cornell Med. Ctr., New York, NY, Rancho Los Amigos Hosp., Downey, CA.

The term transmural myocardial infarct (MI) is frequently used as a synonym for significant Q waves in the electrocardiogram (ECG). The purpose of this study was to determine if these two terms are equivalent. The presence or absence of significant Q waves in transmural and non-transmural MI's was studied by quantitative postmortem analysis of human hearts with a single MI. Patients were excluded if the ECG showed left or right ventricular hypertrophy, bundle branch block, or fascicular block. Each of 66 hearts was cut into 5-7 slices and the percent of the left ventricle (LV) infarcted was determined by computer-assisted planimetry. An MI was called transmural if it extended to the epicardium for at least 1 cm in any slice. Significant Q waves were defined as Q waves $\geq$30 ms in any of these leads: I, II, aVL, aVF, or V_1-V_6; an R wave $\geq$40 ms in V_1, or an R wave $\geq$ 50 ms in V_2. Mean size of 37 transmural MI's (23% of the LV $\pm$ 12% S.D.) was greater ($P<0.001$) than that of 29 non-transmural MI's (7%$\pm$5%). ECG's of all cases of transmural MI's and 20 cases (69%) of non-transmural MI's had significant Q waves. Mean MI size for the 20 non-transmural cases with significant Q waves (9%$\pm$6%) was larger ($P<0.001$) than that for the 9 non-transmural MI's without significant Q waves (3%$\pm$2%). Thus the terms Q wave and transmural MI are not synonymous, rather a significant Q wave indicates a large or medium sized MI, whether or not it is transmural. A single MI without associated Q waves is small.

DOES MYOCARDIAL SCAR SIZE PREDICT THE ELECTROCARDIOGRAPHIC FRONTAL PLANE AXIS?

Christopher J. Havelda, MD; R. Chris Hand; Nancy C. Flowers, MD, FACC; Leo G. Horan, MD, FACC; University of Louisville, Louisville, Kentucky.

In order to demonstrate the influence of myocardial scar size on the observed frontal plane axis of the electrocardiogram, serial dissections were undertaken in 1410 human hearts in which correlative electrocardiograms were available within 90 days of death. A strict protocol was employed requiring independent weighing of right and left ventricles and quantitation of myocardial scar size in each of 15 left ventricular zones. A predicted frontal plane axis was derived from a computational model in each of 422 specimens bearing myocardial scars. This model comprised 15 left ventricular and 4 right ventricular segments with vectors perpendicular to the activation wave front of each segment. The vector in each left ventricular segment was reduced proportionate to the amount of myocardial scarring in that segment and a predicted frontal plane axis for each specimen was derived by summation of these 19 resultant vectors. Multivariate analysis comparing the observed frontal plane axis with left ventricular weight, right ventricular weight, and age, demonstrated poor correlation ($r=0.283$). Bivariate analysis comparing the observed frontal plane axis with the predicted frontal plane axis demonstrated good correlation overall ($r=0.695$). When hearts with small scars (no zone invaded by > 33%) were excluded, the correlation rose to 0.739 ($n=216$). The 99% confidence limits for this correlation are 0.647 to 0.808. Hence, in the presence of myocardial scarring, the quantitative loss of vectorial forces primarily determines the resultant observed frontal plane axis.

DETERMINATION OF CARDIAC DIPOLE LOCATIONS DURING VENTRICULAR RECOVERY IN NORMAL MEN. David M. Mirvis and Mark A. Holbrook, University of Tennessee, Memphis, TN.

Dipole ranging is a method to quantitatively determine the location, moment and sense of the heart vector or dipole from body surface measurements. This technique was applied to ECG data recorded from 150 torso electrodes on 45 normal men. Signals were processed to yield isopotential maps and to compute the 6 terms (X,Y,Z locations and X,Y,Z moments) of the dipole best fitting the recorded potentials at 2 msec intervals during QRST. Dipole terms were calculated by solving the Gabor-Nelson surface integration formulae. During QRS, the dipole locations were often extrathoracic; this correlated with isopotential patterns that were overtly nondipolar. In contrast, all maps during STT were dipolar in form. The cardiac dipole remained relatively stationary during STT. Forty msec into STT, the mean location was 1.29" to the left and 1.02" anterior to the center of chest at a level 5.54" below the sternoclavicular joint. Mean location moved only 0.53" throughout the STT. The standard deviation of distance from each location to the mean site was 0.70". Thus, dipole locations were closely grouped near the cluster center, which approximated a point near the left ventricular free wall. Dipole moments rose progressively to a peak during T (0.53± 0.20 mA-cm). Orientation remained inferior, leftward and anterior during STT, with less than a 10 degree shift. Thus, the dipole during most of repolarization may be modeled as a fixed location, fixed orientation, variable strength electrical source. Dipole ranging can therefore provide physiologically relevant information when applied to clinical electrocardiographic problems; localization of the cardiac source is not possible with other ECG techniques.

NONINVASIVE HIS BUNDLE RECORDING. EXPERIENCE FROM THREE YEARS OF CLINICAL TRIALS

John J. Rozanski, MD, Agustin Castellanos, MD, FACC; Richard Luceri, MD, Barry R. Alter, MD, FACC; Richard G. Pozen, MD, Robert J. Myerburg, MD, FACC; VA Hospital and University of Miami, Florida

Non-invasive His bundle recordings (HBE) were performed in 55 consecutive patients (pts) also undergoing intracardiac HBE for various forms of conduction system disease to provide a study group with a wide variety of P-H and H-V intervals. Signal input noise discrimination, amplification, and averaging of 1024 cardiac cycles were performed. Clearly defined non-invasive HBE were obtained in 25/55 pts (45%). In this group correlations with invasive P-H and H-V intervals were good, r = +0.88 and +0.97, respectively. Failure to record a satisfactory HBE occurred in 30/55 (55%). Of these, prolonged atrial activity obscured the non-invasive HBE in 17/55 (31%). A short A-H likewise obscured the HBE in 5/55 (9%). In 8/55 (15%), a clear HBE could not be extracted from background noise, due in 4 pts to high impedence at one or more skin electrodes. Optimal lead location for recording the HBE varied from pt to pt: V_1, V_2, V_6 or V_1, V_4, V_9 were usually satisfactory locations. First degree AV block or A-H prolongation virtually assured detection of HBE (95%). Conversely, short A-H, short P-R, or intra-atrial conduction delay in the standard ECG made non-invasive HBE recording virtually impossible. In conclusion, an accurate non-invasive HBE can be recorded in most patients with first degree heart block or long A-H intervals. This HBE is reproducible and correlates well with invasively measured HBE.

PROGNOSIS AFTER INFARCT: STRATIFICATION BY Q WAVE EVOLUTION

Alan G. Wasserman, MD; Jorge C. Rios, MD; George B. Bren, MD; Richard J. Katz, MD; Daniel Bogaty, BS; Allan M. Ross, MD, FACC, For the Aspirin Myocardial Infarction Study Group, George Washington University, Washington, D. C.

Loss of ECG Q waves after myocardial infarction (MI) has been considered a sign of localized damage implying a favorable prognosis. We tested this hypothesis in the 4230 patients (pts) of the Aspirin Myocardial Infarction Study (AMIS). As aspirin vs placebo comparison showed no long-term mortality difference, data was pooled for both treatment groups. Follow-up averaged 38.2 months. There were 602 pts (14.2%) who had diagnostic Q waves at the time of MI but lost these Q waves by randomization. There was no difference in total mortality for pts losing Q waves (39/602, 6.5%) versus those with persistent single ECG defined infarct sites (205/2354, 8.7%, p=ns). Because stratification of pts by loss vs persistence of Q wave carried no prognostic value, further analysis was performed using the Minnesota Code for major, moderate or minor infarct pattern (based upon duration of Q's and Q/R ratio) and the distribution criteria for multiple site infarcts. Total mortality for single ECG defined infarct sites revealed a higher mortality in the major subgroup (106/999, 10.6%), than in the moderate (55/763, 7.2%, $p < .01$) or the minor subgroup (44/592, 7.4%, $p < 0.01$). Those pts with multiple ECG infarct sites also had a significantly higher mortality, 186/1274, 14.6% compared with those pts with single infarct sites, 244/2956, 8.2% $p < 0.02$.

Conclusion: 1) Q wave loss does not portend an improved prognosis; 2) Electrocardiographic criteria for extensiveness of infarct does identify subgroups with increased long-term mortality rates.

ELECTROCARDIOGRAPHIC "LOW VOLTAGE, ANTERIOR WALL MYOCARDIAL INFARCT PATTERN, ARRHYTHMIAS AND ABSENCE OF LEFT VENTRICULAR HYPERTROPHY"-THE CHARACTERISTIC ELECTROCARDIOGRAM OF AMYLOID HEART DISEASE FROM ANALYSIS OF 40 NECROPSY PATIENTS

Bruce F. Waller, MD, and William C. Roberts, MD, FACC, National Heart, Lung and Blood Institute, Bethesda, MD

Little information is available correlating the electrocardiogram (ECG) and necropsy findings in patients (pts) with cardiac amyloidosis (A). Thus, ECG's were reviewed in 40 pts with cardiac A. All ECGs were abnormal and all 40 hearts had A present in the right (R) and left (L) atria, R and L ventricular free walls and ventricular septae. All pts had clinical cardiac dysfunction. Clinical diagnosis of non-cardiac A had been made in 17 (43%) and a diagnosis of cardiac A in only 4 (10%). ECG findings were: low voltage in 38 (95%); myocardial infarct pattern in 38 (95%) (anterior=36 [95%], posterior=4 [11%]); arrhythmia in 36 (90%)(atrial=34 [89%], ventricular=25 [66%]); atrio-ventricular block in 31 (78%)(1° in 21 [53%], 2° in 5 [13%], 3° in 5 [13%]); abnormal QRS axis in 22 (56%)(R in 8 [20%], L in 14 [35%] and complete bundle branch block in 14 (35%)(R=8 [20%], L=6 [15%]). No pt had ECG voltage criteria for left ventricular hypertrophy (LVH) despite increased heart weights in all 40 (380 to 800 gms, mean=590) and a history of systemic hypertension in 20 (50%). Thus, in pts with cardiac dysfunction, in the absence of chest pain and valvular heart disease, low voltage, anterior wall infarct pattern, arrhythmia and absence of LVH on the ECG suggests cardiac A, and these findings are nearly diagnostic of cardiac A in pts with known non-cardiac A.

PARTIAL ATRIOVENTRICULAR CANAL DEFECT IN ADULTS

John K. Hynes, MD; Abdul J. Tajik, MD, FACC; James B. Seward, MD, FACC; Valentin Fuster, MD, FACC; Donald G. Ritter, MD, FACC; Robert O. Brandenburg, MD, FACC; Francisco J. Puga, MD; Gordon K. Danielson, MD, FACC; Dwight C. McGoon, MD, FACC, Mayo Clinic, Rochester, MN.

Partial atrioventricular canal defect (PAVC) is rare in adults (≥20 years), hence little is known of the clinical profile, and surgical experience is limited. Between 1958-January 1980, 47 patients (pts) (28 females, 19 males) mean age 36 years (range 20-75) were seen; 15 pts (32%) were >45 years old. Thirty-seven were in functional Class I or II and 10 were in Class III or IV. Right bundle-branch block and left axis deviation were present in 43 pts (91%). Surgical repair was performed in 43 pts (4 declined surgery); 34 had preoperative catheterization. Mean Qp/Qs was 3.0, mean pulmonary artery pressure ≥25 mm Hg (range 25-50) in 8 pts. "Gooseneck" deformity of the LV outflow tract was not readily apparent in 3 pts on left ventriculography. Of the 9 noncatheterized pts, 8 had a correct preoperative diagnosis. Mitral cleft was sutured in 37 of 43 pts. Operative mortality was 7% (3 of 43 pts), with no operative deaths since 1975 (15 pts, 4 of them >50 years). Although mitral regurgitation was moderate to severe in 9 pts, only 2 had valve replacement. No complete heart block occurred. On follow-up of 3-269 months (mean 83) 2 deaths had occurred--at 3 months (mitral prosthesis malfunction) and 31 months (congestive heart failure). All survivors are in Class I or II. Five pts are on antidysrhythmic medication. No long-term survivor has required reoperation or pacemaker insertion. CONCLUSION: This is the first study detailing the clinical profile and management of a large group of adults with PAVC. Surgical repair in this age group can be performed at low risk and with gratifying long-term results.

LATE RESULTS OF CORRECTION FOR TETRALOGY OF FALLOT: A LONG-TERM, FOLLOW-UP EVALUATION OF 300 PATIENTS

Karl J. Karlson, MD; Michael Jones, MD; James S. Donahoo, MD; Catherine A. Neill, MD; J. Alex Haller, Jr., MD; Vincent L. Gott, MD, Johns Hopkins Hospital, Baltimore, Md.

To evaluate the potential for normal lifestyle late after repair for tetralogy of Fallot, we performed a follow-up evaluation of 300 consecutive patients (pts) undergoing operation from 1965-1975. Mean age at operation was 13 years (yrs) (1-35 yrs) and at follow-up 21 yrs. There were 29 (10%) early deaths. Late evaluations were performed at least 5 yrs and up to 15 yrs (mean 8 yrs) after correction by clinical examination (76%) and correspondence (24%). Of 271 early survivors, 88% were available for evaluation. Postoperative catheterizations were performed in 140 (59%). Late results were classified as good (no symptoms, no cardiac medications, RV pressure < 60 mmHg and/or < 50% Ao pressure, left-to-right shunt < 1.4/1.0, and an active lifestyle); fair (any activity restriction, any cardiac medication, any arrhythmia except RBBB, any right-to-left shunt, and/or valvar regurgitation); or poor (reoperation, severe activity restriction, RV pressure = Ao pressure, heart block, and/or severe valvar regurgitation). Good results were present in 156 (66%), fair results in 47 (20%), and poor results in 21 (8%). Reoperation was required in 14 (6%); no deaths occurred. There were 14 (6%) late deaths: 9 sudden, 3 from failure, 1 from endocarditis, 1 from cerebral embolus. Actuarial survival is 87% at 5 yrs (n=271), 83% at 10 yrs (n=183), and 77% at 15 yrs (n=24). Actuarial probability of obtaining a good or fair result is 79% at 5 yrs, 74% at 10 yrs, and 60% at 15 yrs. At follow-up in 48 pts < 14 yrs of age, mean height ↑ 13 %ile and weight ↑ 19 %ile. Of 138 pts > 18 yrs of age, 25% are married and 51% are employed. Thus, most pts with tetralogy of Fallot may anticipate satisfactory late results.

A FIVE YEAR FOLLOW-UP OF AORTIC HOMOGRAFT MONOCUSPS USED IN RECONSTRUCTION OF THE RIGHT VENTRICULAR OUTFLOW TRACT IN INFANTS WITH TETRALOGY OF FALLOT.

Rosemary Radley-Smith, Charles Ilsley, Colin Reid and Magdi Yacoub, Harefield Hospital, London, U.K.

A monocusp of a fresh adult-sized antibiotic sterilised aortic homograft was used to enlarge the pulmonary valve ring and to render the valve competent in fourteen infants under the age of 2 years undergoing primary total correction of Tetralogy of Fallot. Their ages were 4-24 months. These children have now been followed up for a minimum period of 5 years (5 - 8.1 years) mean 6.15 years. All are asymptomatic and not on cardiac drugs. Five patients (35%) have developed a grade I-II early diastolic murmur 0.4 years after operation, with no significant increase in heart size on chest radiograph. All patients have been routinely reinvestigated 2 weeks - 54 months after operation. Seven have been reinvestigated again at least 2 years after the initial restudy. Thirteen patients had a RVOT gradient of less than 15mmHg and the RV/LV ratio was less than 0.4 in 12. The RVEDP was less than 12 mmHg. In the patients reinvestigated twice there was no significant change in RVOT gradient, RV/LV ratio or RVEDP. There is no angiographic evidence of severe pulmonary regurgitation.

It is concluded that monocusps used in the reconstruction of the RVOT in patients with Tetralogy of Fallot operated upon under the age of 2 years appear to allow for growth and give good long-term results.

MUSTARD'S OPERATION IN THE FIRST MONTH OF LIFE

Leonard L. Bailey, MD, FACC, John G. Jacobson, MD, FACC, William H. Merritt, MD, Robin W. Doroshow, MD, and Eugene L. Petry, MD, Divisions of Cardiovascular Surgery and Pediatric Cardiology, Loma Linda University, Loma Linda, California 92350.

Since April 1976, Mustard's interatrial baffle procedure has been accomplished in seven newborns with Transposition of the Great Arteries (TGA) under one month of age who were persistently symptomatic following Rashkind's balloon atrioseptostomy. Two had associated large ventricular septal defects (VSD) patched at the time of physiologic correction. Average age was 11 days (36 hrs. - 28 days). Weight averaged 3.4 kilograms (2.7 - 4.2). All were done using deep hypothermic circulatory arrest, averaging 65 minutes (48-87 minutes) at a mean core temperature of 12.5° C. A mean of 2.8 days of post-operative ventilatory assistance was required. One death occurred in a 28 day-old male with associated VSD who, the morning after surgery, developed sudden unresponsive cardiac standstill. Post-operative hospitalization averaged 15 days (10-23 days). Follow-up evaluation has extended from 3 to 56 months, averaging 34.3 months. Five patients have been re-studied 10-21 months post-operatively. One had obstruction of the superior limb of the baffle which had separated from the right atrial wall permitting a modest right to left shunt. She has had uneventful repair employing a unique modification of Senning's operation. Another child has assymptomatic partial obstruction of the superior limb of the baffle demonstrated angiographically. No other intracardiac shunts have been identified. None have pulmonary venous obstruction and all are in prevailing normal sinus rhythm. Early correction of persistently symptomatic neonates with TGA with or without VSD has obviated the need for palliative operations and produced gratifying early and late results.

COMPLETE ATRIOVENTRICULAR CANAL ASSOCIATED WITH TETRALOGY OF FALLOT

Gideon Uretzky, MD; Francisco J. Puga, MD; Robert H. Feldt, MD, FACC; Paul R. Julsrud, MD; William D. Edwards, MD; Gordon K. Danielson, MD, FACC; Dwight C. McGoon, MD, FACC; Mayo Clinic and Mayo Foundation, Rochester, Minn.

The surgical repair of complete atrioventricular canal associated with tetralogy of Fallot has been reported in a few cases. Between 1969-1979, a total of 14 patients with the combination of complete atrioventricular canal (13 type C, and 1 type B), associated with tetralogy of Fallot, had repair of both anomalies. Patient age ranged from 1 to 12 years. Five had a previous shunt operation, 13 had combined subpulmonary and valvular stenosis and 1 had subpulmonary stenosis only. Six patients had Down's syndrome. Eleven (79%) had associated anomalies including left superior vena cava (3), right aortic arch (2), atrial septal defect secundum type (7), patent foramen ovale (1), anomalous left anterior descending coronary artery (1), and aberrant right subclavian artery (1). The precise preoperative diagnosis was established in 10 (71%) by angiography showing the characteristics of tetralogy of Fallot on RV angiogram and those of atrioventricular canal on LV angiogram. In 4 of these patients the diagnosis was supported by two dimensional echocardiography. The typical features of the condition include anterior displacement of the infundibular septum and "goose neck" LV outflow changes. Surgical repair is complex. The repair of the ventricular septal defect, with its large anterior subaortic extension required a combined atrial and right ventricular approach in 4 patients. Outflow tract reconstruction (transanular patch) was performed in 9 patients. The hospital mortality rate was 21%, and there were two late deaths. Nine (64%) patients are still living having a satisfactory result.

CONDUIT SURGERY FOR RIGHT VENTRICULAR AND PULMONARY ARTERY CONTINUITY. EXPERIENCE IN BOTH INFANTS AND OLDER CHILDREN.

Constantine Mavroudis, MD; Kevin Turley, MD, FACC; Paul A. Ebert, MD, FACC; University of California, San Francisco, CA 94143.

The conduit repair (Rastelli) of lesions requiring reconstitution of right ventricular (RV) to pulmonary artery (PA) continuity has been demonstrated effective. Serious questions have arisen as to the longevity of such conduit replacements with degeneration of the valve components and the development of gradients at both the anastomotic, conduit, and valvular levels. These are of special import in the infant group. During the period June 1, 1975-July 1, 1980, 110 RV to PA conduit repairs were performed at University of California, San Francisco. Ages ranged from 14 days to 35 years, median 15 months. Lesions included truncus arteriosus, transposition of the great arteries with ventricular septal defect, tetralogy of Fallot and pulmonary atresia. Conduit size ranged from 12 to 22 mm, median 14 mm. Overall operative survival was 80%. Special risk factors identified included absence of pulmonary arteries, associated lesions (i.e. interrupted arch, valvular insufficiency requiring replacement) and age < 6 weeks. When such patients were excluded, survival was 90%. 10 conduit replacements were undertaken at a mean of 27 months in follow-up, while 100 patients from 3 months to 68 months postop. remain at risk. Operative survival in repaired patients in whom replacement was necessary was 100%. Conduit repair of RV to PA discontinuity results in stimulation of symmetrical anatomic growth and hemodynamic repair. Reoperation is necessary in these patients in response to both this growth and the intrinsic problems of valvular degeneration and pseudointimal proliferation associated with current conduits, but replacement is possible with low risk.

DECREASED MYOCARDIAL OXYGEN DEMAND FROM EXERCISE TRAINING SECONDARY TO IMPROVED WORK EFFICIENCY: EFFECT OF HABITUATION VERSUS AEROBIC CONDITIONING

Rudolph H. Dressendorfer, PhD; Joan L. Smith, MA; Ezra A. Amsterdam, MD, FACC, Human Performance Lab, University of California, Davis, California.

Exercise training (ExT) in coronary patients (pts) has been shown to improve aerobic capacity, as measured by an increase in total body maximal oxygen consumption ($\dot{V}O_2$ max), and to decrease myocardial oxygen demand ($M\dot{V}O_2$) during submaximal Ex. The lowering of $M\dot{V}O_2$ with Ex at the same external workload after training most often results from utilization of a decreased percentage of $\dot{V}O_2$max because of greater aerobic capacity. Our purpose was to determine whether $M\dot{V}O_2$ during submaximal walking Ex could be reduced by improving work efficiency without a concomitant increase in $\dot{V}O_2$max. The pts were 8 men with ischemic heart disease who did not have symptom-limitations on maximal Ex testing. ExT was restricted to fast walking since jogging caused ischemic ST-segment depression. Walking speed was individually prescribed between 3.4 to 4.7 mph in order to maintain the heart rate (HR) x systolic blood pressure product just below the ischemic threshold. After 14 to 20 wks of ExT 3 x per wk, directly measured $\dot{V}O_2$max was not significantly changed. However, significant ($P < .05$) reductions in HR (120 to 108 beats/min), rate-pressure product (195 to 162 x 10^2), total body $\dot{V}O_2$ (20.0 to 18.2 ml/kg/min) and perceived exertion were found after ExT when the pts walked at their prescribed speeds. Total body $\dot{V}O_2$ during submaximal Ex was reduced secondary to habituation, i.e., enhanced work efficiency. Consequently, estimated $M\dot{V}O_2$ was significantly lower after ExT due to decreased peripheral oxygen demand, and not because of a reduction in the relative workload. Coronary pts may benefit from regular Ex even when aerobic capacity is not increased.

DAILY EXERCISE AUGMENTS ANTEGRADE FLOW FOLLOWING PARTIAL CORONARY OCCLUSION

Ming Hwang, MD, FACC; Alan Gabster, MD; Henry Loeb, MD, FACC; Rolf Gunnar, MD, FACC, Loyola University Medical Center, Maywood, Il and VA Hospital, Hines Il

Previously we showed that dogs subjected to daily treadmill exercise (45 min, 4-6 mph, 10° slope for 4-6 weeks) increased subendocardial blood flow (SEF) in an area supplied by partial (80-90%) circumflex artery occlusion ($P\text{-}CF_xO$) when compared to similar dogs not exercised. All visible epicardial collaterals were ligated. To determine if the increased flow was across the partial constriction or from collaterals, 22 dogs were prepared as above. Posterior SEF was measured after $P\text{-}CF_xO$ and after total circumflex occlusion (TCF_xO) to assess the proportion SEF which was antegrade. Results: In 6 experiments, PSEF measured immediately after PCF_xO averaged .74±.20 ml/min/gm (Mean ± SEM) falling to .10±.03 ml/min/gm upon TCF_xO ($p<.001$). In 16 dogs, PSEF measurements were made 4-6 weeks after PCF_xO. Eight dogs remained sedentary and 8 underwent daily exercise. In the 8 sedentary dogs, PSEF with PSF_xO averaged .94±.12 ml/min/gm falling to .64±.11 ml/min/gm upon TCF_xO (NS). In the 8 exercised dogs, PSEF with PCF_xO averaged .95±.15 ml/min/gm falling to .38±.15 ml/min/gm after TCF_xO ($p<.05$). Conclusion: Immediately following PCF_xO, PSEF depends primarily on antegrade flow. After 4-6 weeks, retrograde collateral flow makes a significant contribution to PSEF in sedentary dogs. Dogs subjected to daily exercise following PCF_xO have a very significant increase in the proportion of blood flowing antegrade across the PCF_xO. Therefore, daily exercise seems to enhance antegrade flow in PCF_xO dogs. It is proposed that this enhanced antegrade flow is due to an effect of daily exercise on myocardial vascular resistance.

DOES LV FUNCTION REACH A STEADY STATE DURING SUSTAINED EXERCISE?

Shelley Magder, MD; Joseph Hung, MD; William M. Savin,MS; Edward B. Stinson, MD, FACC; George T. Daughters II, MS; Neil B. Ingels, Jr., PhD: Edwin L. Alderman, MD, FACC, Stanford University, Stanford, CA.

Exercise (Ex) studies often assume that a hemodynamic steady state is reached in 3 min. Eleven asymptomatic males 4 to 6 years post aorto-coronary bypass did supine Ex at 450 KPM/min for 3-6 min (mean 5.3). Cardiac output (CO), heart rate (HR), stroke volume (SV), ejection fraction (EF), and circumferential shortening velocity (VCF) were measured by computer assisted analysis of the motion of implanted midwall markers.

RESULTS:	CO	HR	SV	EF	VCF
	l/min	beats/min	ml	%	circ/sec
CONTROL	5.6(1.6)	67(10)	84(21)	48(4)	.61(.16)
Ex min 1	8.6(2.3)*	99(13)*	87(23)	50(6)	.85(.20)*
Ex min 3	9.8(2.2)*	112(13)*	89(22)	50(7)	.94(.26)*
PEAK CO	10.9(2.7)*	118(13)*	93(26)*	53(7)*	1.03(.28)*

mean (SD); Ex versus CONTROL *$p<0.01$

CO increased by 75% ($p<0.01$) between control and 3min Ex and by 25% ($p<0.01$) between 3 min and end Ex. This increase was primarily accounted for by an increase in HR with a lesser contribution by SV. Over 85% of the heart rate change occurred within the first 3 min whereas over 40% of SV and 60% of EF increases occurred after 3 min. We conclude that steady state cardiac output and LV function is often not reached within 3 min. Cardiac output may continue to rise later in exercise due to late increases in EF and SV probably due to circulating catecholamines.

ENHANCED OXYHEMOGLOBIN DISSOCIATION CONTRIBUTES TO UNLOADING OXYGEN AT REST AND DURING EXERCISE IN SEVERE CHRONIC HEART FAILURE PATIENTS

Mark Nemerovski, MD; Stanley A. Rubin, MD, FACC; Harvey Brown, MD; David Mickle; H.J.C. Swan, MD, PhD, FACC, Cedars-Sinai Medical Center, Los Angeles, California

Maximum oxygen transport is abnormally low in heart failure. Therefore, we studied the potential mechanisms for increased unloading of oxygen in 15 chronic heart failure pts at rest (R) and during maximum cycle ergometry (E). We measured cardiac index (CI) by thermodilution, oxygen consumption (VO_2) by expired air analysis, mixed venous pO_2 and pH by electrodes and oxyhemoglobin saturation (S) by oximetry. Arteriovenous O_2 difference ($AV\text{-}O_2$) and P_{50} (pH=7.4, T=37°C) were calculated. At R, CI was 1.8±0.31/min/m^2 (mean±SD) and rose slightly but significantly during E to 2.4±0.7, ($p<0.01$). At R, VO_2 was 140±20 ml/min/m^2 and rose substantially during E to 290±80 ($p<0.01$). At R, $AV\text{-}O_2$ was 8.1±1.8 ml/100 ml and rose substantially during E to 12.5±3.4 ($p<0.01$). At R, mixed venous pH (MVpH) was normal (7.4±0.05) and therefore made no contribution to enhanced oxyhemoglobin dissociation (OHD). However, P_{50} was increased to 29.8±3.5 torr (normal 26.9 torr, $p<0.01$), accounting for 16% of peripheral O_2 consumption ($AV\text{-}O_2$). At E, P_{50} remained elevated at 30.9±5.8 torr. In addition, however, MVpH was decreased to 7.34±0.06 ($p<0.05$ cf. control) causing a further shift in OHD by the Bohr effect. At E, enhanced OHD also accounted for about 15% of the $AV\text{-}O_2$. After vasodilator therapy (hydralazine or minoxidil), R and E MVpH were 7.44±0.03 and 7.37±0.04 and P_{50}s were 27.2±1.5 and 27.9±1.8 torr respectively. We conclude that peripheral O_2 consumption in the chronic heart failure patient depends in part on a shift in OHD, and is less dependent on this compensatory mechanism after vasodilator therapy.

CHANGES IN LEFT VENTRICULAR VOLUMES DURING UPRIGHT EXERCISE IN PATIENTS WITH CORONARY ARTERY DISEASE

Abdulmassih S. Iskandrian, MD, FACC, A-Hamid Hakki, MD, Bernard L. Segal, MD, FACC and Sally A. Kane, RN. Cardiovascular Institute, Hahnemann Medical College and Hospital, Philadelphia, Pennsylvania.

We studied 24 patients (pts) with coronary artery disease (CAD) using symptom-limited upright exercise (EX) on a bicycle ergometer. First-pass radionuclide angiograms were obtained at rest (R) and peak EX. Fifty percent of the pts had previous transmural infarctions (MI). Twelve normal men (NL) served as a control. Nine pts developed angina or ST depression during EX. The EX heart rate (HR) and EX tolerance were lower in pts than normal ($p < .01$).

	LV-EDV (ml)		SV (ml)		CO (L/min)		LV-EF	
	R	EX	R	EX	R	EX	R	EX
No MI	174±41	185±40	95±25	90±32	7.2±2.6	*12.7±5.3	55±10	*49±12
MI	229±99	253±98	76±25	89±35	4.9±1.3	*10.2±2.7	38±13	38±12
NL	150±28	170±35	92±15	*125±20	7.5±0.9	*19.8±3.9	62±6	*75±5

{LV, left ventricle; EDV, end-diastolic volume measured by area-length method; SV, stroke volume; CO, cardiac output; EF, ejection fraction; *, $p < .01$, R vs EX}. Six NL and 12 pts had ≥ 10% increase in EDV during EX. The remaining had either no change or decrease. Pts with MI had higher EDV at R and EX than NL ($p < .01$). However, there was no significant difference between R and EX-EDV (and the change in EDV during EX) in NL compared to pts (with or without MI). The SV, CO and EF were higher in NL than pts with CAD during EX ($p < .01$). We conclude: There are significant differences in the SV, CO, HR and EF between NL and pts with CAD during upright EX. However, LV dilatation is neither sensitive (50%) nor specific (50%) for CAD. Moreover, LV dilatation is not affected by the resting EF or by presence of previous MI.

ALTERATIONS IN PLASMA LIPOPROTEIN LEVELS DURING HIGH MILEAGE RUNNING

Rudolph H. Dressendorfer, PhD; Charles E. Wade, PhD; Conrad Hornick, PhD; Ezra A. Amsterdam, MD, FACC, Human Performance Laboratory, University of California, Davis and Tripler Army Medical Center, Honolulu, Hawaii.

Effects of long-distance running on plasma lipoprotein levels were studied using twelve male marathon runners, mean age 40, who ran on the average of 17.3 mi/day for ten days, rested for 70 hr, then continued to run for eight more days. Body weight and percentage body fat were unchanged despite an estimated caloric intake of 4800 kcal/day. Blood samples were obtained on eight mornings prior to running. No significant change in total cholesterol (C) or low density lipoprotein-C was found. Compared to control values, high density lipoprotein (HDL)-C increased 18% and triglycerides (TG) decreased 22% after one week of running, and the observed changes were inversely correlated. The 70-hr rest period disrupted this significant rise in HDL-C and fall in TG. However, with continued running HDL-C and TG returned to pre-rest period values. The findings suggest that increased HDL-C with exercise training is coupled to the mechanism which lowers plasma TG. More importantly, detraining effects on plasma HDL-C and TG may be observed within days of stopping exercise when caloric intake remains high.

EFFECT OF BETA BLOCKADE THERAPY ON HYPERTENSIVE CARDIAC HYPERTROPHY

M.Mohsen Ibrahim,MD,FACC; M.Aziz Madkour,MB,BCh Ragaa Mossallam,MB,BCh, University of Cairo and Cairo Transport Organization,Cairo,Egypt.

The effect of B-blockade therapy on LV mass(LVM) has not been studied in hypertensive patients. Studies in animals have shown that certain anti-hypertensive drugs reduce cardiac hypertrophy. Atenolol(A)- a cardioselective beta blocker with no intrinsic sympathomimetic activity- was given(100mg/d) for 8 weeks to 17 male patients with essential hypertension (mean age 49y) and without evidence of other cardiac disease. Echocardiographic dimensions (ED)and urinary epinephrine(UE) were determined after 4 weeks placebo and after A therapy. ED were measured in 16 age matched normotensive males. Septal(S) and posterior wall(PW) thickness(T),LVM index(LVMI),ratio of LVWT to radius(h/r),UE and mean circumferential wall stress (MCS) were all significantly increased($p < 0.01$) in hypertensive patients. Following A blood pressure(BP) decreased from 197/119 ± 5.7/3.9(mean ± SE) to 160/98 ± 2.9/2.3 mmHg($p< 0.001$), ST from 11.1 ± 0.5 to 10.4 ± 0.4 mm ($p <0.05$), LVMI from 126 ± 10.1 to 112 ± 8.5 gm/m^2 ($p <0.005$), MCS from 342 ± 20.1 to 264 ± 17 $10^3 dynes/cm^2$ ($p <0.001$), end diast.diameter(EDD) from 51.9 ± 1.3 to 50.8 ± 1.4 mm ($p < 0.05$) and UE from 149 ± 9.6 to 91 ± 4.4 mcg/24hs.($p <0.001$). PWT and h/r did not change. Δ LVMI was significantly related to Δ MCS($r = 0.42$),poorly related to Δ syst.BP($r = 0.32$)and Δ UE($r = 0.22$)and not related to Δ diast.BP($r = 0.03$). CONCLUSION:1.A produced a rapid decrease in LVM,however,some of the changes might be due to a decrease in EDD since h/r did not change.2.Regression of cardiac hypertrophy appears to be more dependant on reduction in wall stress than a direct hypotensive effect of therapy or decrease in adrenergic activity (UE).

EFFECTIVE AND SAFE TREATMENT OF HYPERTENSIVE CRISIS WITH NIFEDIPINE.

Dieter Magometschnigg, M.D.; Max Pichler, M.D.; I. Medizinische Universitätsklinik, Wien, Austria

The present management of hypertensive crisis with nitroprusside, diazoxide or hydralazine requires close monitoring of blood pressure (BP) and dose of the administered drug due to possible side effects.
We investigated the effectiveness and safety of nifedipine to patients with hypertensive crisis. Twenty milligrams nifedipine were given orally to 7 pts. suffering from a marked rise of blood pressure of > 25o mmHg systolic and >14o mmHg diastolic as well as typical clinical manifestations (headache, nausea, visual loss, restlessness and confusion). Blood pressures were measured by the method of Riva Rocci. Blood pressure and heart rate were taken 2o, 1o minutes and immediately before application and 1o, 2o, 3o, 45, 6o and 9o minutes later. Results (mean ± SD) were as follows:

	-2o	-1o	o	1o	2o	3o	45	6o	9o min.
syst. BP	272 32	256 26	257 4o	237 28	179 28	177 27	177 22	176 25	176 28
diast. BP	159 18	158 1o	157 13	147 9	121 16	1o5 15	1o2 14	98 19	1o4 13
HR	69 17	68 17	71 16	64 19	74 19	77 19	74 18	74 19	73 17

Nifedipine caused in all patients a prompt decrease of the elevated blood pressure. Its onset was within 1o minutes and reached the maximal effect by 3o minutes. The drop of blood pressure was concomitant with a marked improvement of symptoms. Of importance, there were no signs of overshoot or tachycardia. Therefore, nifedipine appears to be both a safe and effective drug in the management of acute hypertensive crisis.

EVIDENCE FOR ALTERED VASCULAR REACTIVITY IN YOUNG SUBJECTS WITH LABILE, BORDERLINE HYPERTENSION

Jay M. Sullivan, MD, FACC; Darrell R. Patrick, BS; Steve W. Reed, MD; Ahmad Banna, MD; John C. Riddle, MD; Collier Jordan, MD, University of Tennessee, Memphis, TN

Forearm hemodynamics were measured by venous occlusion plethysmography during periods of ad lib diet, 10 mEq sodium diet and 200 mEq sodium diet in 15 normal subjects (NL) and 15 subjects with labile, borderline hypertension (BBP). The two groups did not differ significantly in regard to age, sex or race. Average resting blood pressure (BP) in the normal group was 110/74 and 122/85 in the BBP group ($p<.005$). Resting forearm blood flow (FBF), forearm vascular resistance (FVR), venous compliance (VC) and capillary filtration coefficient (CFC) did not differ significantly between the two groups. In both groups, diastolic blood pressure was highest when first measured during the ad lib state (81 mmHg) and lower during the 10 mEq (79 mmHg) and 200 mEq (78 mmHg) sodium state ($p<.01$). Venous capacitance was lowest during the ad lib state, 0.50 vs 0.70 and 0.57 ml/min/mmHg/100 g x 10^4 ($p<.05$). In the normal group, the 10 and 200 mEq sodium diets had little effect on forearm hemodynamics. Sodium depletion brought out a difference between the NL and BBP subjects. The FVR of the BBP subjects rose significantly during salt depletion, 35.9 vs 60.9 mmHg/ml/min/100 g ($p<.05$) while that of the NL subjects did not. Sodium sensitivity was arbitrarily defined as an increase in mean blood pressure of more than 5% when sodium repleted. The individuals who were salt sensitive had a higher FVR during sodium depletion than those who were salt resistant, 64.9 vs 44.6 mmHg/ml/min/100 g ($p<.03$). We conclude that young individuals whose resting diastolic BP intermittently rises above 90 mmHg already have alteration in vascular reactivity.

DIASTOLIC VENTRICULAR ABNORMALITY IN HYPERTENSIVE HEART DISEASE: ATRIAL EMPTYING INDEX

Gerald R. Dreslinski, MD; Edward D. Frohlich, MD,FACC; Francis G. Dunn, MD; Franz H. Messerli, MD,FACC; Daniel H. Suarez, MD; Efrain Reisin, MD. Ochsner Medical Institutions, New Orleans, LA.

Left ventricular (LV) diastolic properties in hypertensive heart disease were analyzed, employing the atrial emptying index (AEI), thereby assessing the rapid phase of LV diastolic filling. 10 normal subjects (Group 1), 11 hypertensive patients without evidence of cardiac involvement (Group 2), and 9 hypertensive patients with ECG and/or echocardiographic evidence of LV hypertrophy (Group 3) were studied by concomitant M-mode echocardiography and systemic hemodynamics. Whereas cardiac index (dye dilution), and fiber shortening rate (V_{cf} by echocardiogram) were similar in all three groups, there was a progressive increase in left atrial index (LAI) (1.30 vs 1.74 and 1.30 vs 1.84 cm/m^2, Group 1 vs Group 2 and Group 3, respectively; $p<0.001$), and a progressive decrease in AEI (0.82 vs 0.63, $p<0.001$, Group 1 vs Group 2, and 0.82 vs 0.60, $p<0.02$, Group 1 vs Group 3). No correlation existed between the AEI and the LAI, mean arterial pressure, or total peripheral resistance, in these three groups.

These data suggest that the LV is less compliant early in hypertension, before ECG, anatomic or LV systolic echocardiographic abnormalities are detectable. AEI, therefore, appears to be an early indicator of abnormalities of LV diastolic compliance, thus far the earliest sign of cardiac involvement in hypertensive disease.

XERCISE TOLERANCE TESTING IN ADOLESCENTS WITH ESSENTIAL /PERTENSION

rthur A. Klein, MD, FACC; Wallace W. McCrory, MD; lchard Rosenthal; Mary Allen Engle, MD, FACC
ıe New York Hospital-Cornell Medical Center, New York

Exercise tolerance was evaluated in racially heterogeneous age-matched adolescent males with essential hypertension (EH) (5), with labile hypertension (LH) (14) and normal blood pressure (NC) (15). All completed 12 minutes on the treadmill (Bruce protocol). Test normals did not differ significantly from our lab normals. Heart response follows:

	AGE (YRS)	BASE-LINE	p vs NORM	MAX	p	2 MIN REST	p	5 MIN REST	p
C	16.7	80±16		167±16		93±17		87±13	
H	16.4	86±11	NS	172±12	NS	108±16	<.01	98±12	<.01
H	15.1	77±14	NS	184±15	<.05	122±28	<.055	108±18	<.005

Lactate levels, sampled from an indwelling venocath. ere:

	BASELINE	p vs NORM	MAXIMAL EXERCISE	p vs NORM
C	11.7±3.9		25.9±8.4	
H	15.5±4.3	<.02	40.4±14.6	<.002
H	16.1±5.1	<.05	43.5±17.3	<.005

We conclude, unlike previously reported data, that 1) EH is associated with higher heart rate response to xercise; (2) both EH and LH differ from NC with a prolonged exercise recovery phase that is most marked in EH; 3) EH and LH also appear to exercise less efficiently as videnced by elevated maximal exercise lactate levels.

K-421: A NEW ORAL ANGIOTENSIN CONVERTING ENZYME INHIBITOR FOR ESSENTIAL HYPERTENSION

oger K. Ferguson, MD, FACC; Peter H. Vlasses, PharmD; rian N. Swanson, PhD; David J. Cooper, MD; Richard O. avies, MD, FACC; William B. Abrams, MD, FACC, Thomas efferson University Hospital, Philadelphia, Penn.

The antihypertensive efficacy of MK-421 (N-[(S)-(ethoxycarbonyl)-3-phenyl-propyl]-L-alanyl-L-proline), a new ngiotensin converting enzyme inhibitor, was evaluated in 1 patients (6 men, 5 women), aged 31-69 years, with uncomplicated mild to moderate essential hypertension. The urpose of the study was to determine an effective dose or subsequent chronic administration. The patients were ospitalized after 2 weeks off all drugs. After 3 days n a 150 mEq Na^+, 80 mEq K^+ diet, mean (±S.D.) sitting lood pressure (BP) was 158/99 ± 11/10 mm Hg and upright lasma renin activity (PRA), 2.2 ± 1.1 ng/ml/hr, plasma aldosterone (PA), 17 ± 8 ng/dl and angiotensin I (AI), 0.51 ± .2 ng/ml. Alternating with placebo, MK-421 was given in ingle daily rising doses (2.5, 5 and 10 mg) depending on he presence and duration of a BP response (decrease in iastolic BP ≥ 10 mm Hg). PRA, PA and AI were measured at , 4, 8, 12 and 24 hr after placebo and each dose of K-421; BP was measured with an automatic device (Dinaap®) at frequent intervals up to 15 hours. After each ose of MK-421, though the mean maximal decrease in diatolic BP was similar (17-21 mm Hg), the mean onset (3.5 o 2 hr) and duration (7 to >13 hr) of the BP response aried with increasing dosage; 2 patients responded for :12 hr at 5 mg and 9, at 10 mg. Mean PRA increased, PA ecreased and AI did not change. Neither the magnitude or the duration of BP response correlated with baseline RA. No adverse effects occurred. Thus, in this study, K-421 proved to be a potent and effective antihypertensive agent with a dose-related onset and duration of effect.

ECHOCARDIOGRAPHY: EXPERIMENTAL AND CLINICAL STUDIES
2:00-3:30

TRANSMISSION OF ECHOCARDIOGRAPHIC CONTRAST THROUGH THE LUNGS.

Richard S. Meltzer, MD; Charles T. Lancée, MSc; Otto E.H. Sartorius; Piet D. Verdouw, PhD; Patrick W. Serruys, MD; Catharina E. Essed, MD and Jos Roelandt, MD, FACC, the Thoraxcenter, Erasmus University and University Hospital, Rotterdam, the Netherlands.

Previous reports of transmission of echocardiographic contrast through a normal pulmonary capillary bed have all been based on pulmonary wedge injections. More proximal-ultimately peripheral-injections would be preferable. We tested two methods of transmitting echocardiographic contrast through the pulmonary capillary bed using injections proximal to the wedge position. We also tested the potential toxicity of echo transmission through the lungs using wedge injections. Method 1: hydrogen peroxide (H_2O_2) was injected in the right heart (RH) in 11 pigs. Method 2: diethyl ether was injected in the RH in 9 pigs. Left heart echo contrast was monitored in pigs by epicardial transducers. Method 3: saline was injected in the pulmonary wedge position in 8 rabbits. They were sacrificed 1 day later and examined for evidence of toxicity. Results - Method 1: nine pigs had left heart echo contrast after 1.5% or higher concentrations of H_2O_2. Ten had ECG changes and/or hypotension after H_2O_2. Method 2: seven pigs had left heart echo contrast after ether. Method 3: there was no definite injury in the lung from wedge injections. Three rabbits had small myocardial infarctions and 1 rabbit had a large infarct and died prior to sacrifice. We conclude that transmission of echocardiographic contrast through the lungs is potentially dangerous. Not only pulmonary wedge injections, but also more proximal wedge injections of selected substances may yield left heart echo contrast in experimental animals. Threshold concentrations of H_2O_2 may be found above which RH injections yield left heart echo contrast.

TRANSMISSION OF ECHOCARDIOGRAPHIC CONTRAST THROUGH THE LUNGS. II : HUMAN STUDIES.

Patrick W. Serruys, Richard S. Meltzer, Jackie McGhie, Jos Roelandt.
The Thoraxcenter, Erasmus University and Dijkzigt Hospital, Rotterdam, the Netherlands.

Pulmonary wedge injections (PWI) have been shown to cause left heart echocardiographic contrast (LHEC). In order to study factors affecting the success of this procedure, hand PWI of 10 cc 5% dextrose were performed in 41 patients (pts) and monitored by two-dimensional echocardiography. Swan-Ganz catheters alone were used in 3 pts, Cournand catheters alone in 27 pts, and both in 11 pts. Ten pts had angiograms during PWI of a non-ionic X-ray contrast agent in the same catheter position used for the echo study. Results : LHEC occurred in 3/14 pts with Swan-Ganz PWI and 30/38 pts with Cournand PWI. Pressure proximal to the catheter was ⩾ 300 mmHg when LHEC was seen. The 2 of 10 pts with retrograde X-ray contrast flow around the catheter failed to achieve LHEC after PWI. No complications occurred. After catheterization, 1/13 pts had an elevated LDH, 3/11 had localized lung scan defects, and 0/11 had localized chest film lesions. We conclude :

1) PWI can yield LHEC,
2) the success of this procedure varies with the type of catheter used,
3) a sufficiently occlusive wedge position must be attained to allow transmission of pressure to the capillary bed if LHEC is to be attained, and
4) the safety of this procedure needs further evaluation.

ULTRASONIC DETECTION OF THE ALTERED ACOUSTIC PROPERTIES OF MYOCARDIUM CHARACTERISTIC OF ADRIAMYCIN-INDUCED CARDIOMYOPATHY

Randolph D. Cohen, MD; James W. Mimbs, MD, FACC; Matthew O'Donnell, PhD; James G. Miller, PhD; Burton E. Sobel, MD, FACC, Washington University, St. Louis, Missouri

To determine whether altered acoustic properties of the heart provide criteria potentially diagnostic of cardiomyopathic changes, we subjected 25 rabbits to prolonged administration of Adriamycin (1.2 mg/kg twice weekly). Rabbits were sacrificed at selected intervals from 10 to 18 weeks after the onset of administration of the drug and their hearts analyzed ultrasonically and chemically. Regional ultrasonic backscatter and collagen content, based on hydroxyproline, were assessed. Backscatter was measured with a frequency averaging procedure (integrated backscatter) to minimize phase cancellation and with an independent method employing spectral display (over the frequency range of 1 to 11 MHz) from which backscatter at 2.25 MHz could be calculated. Cardiac collagen content was significantly increased in fibrotic and myopathic zones of hearts from treated animals as compared to controls ($p < .05$). Integrated backscatter was markedly increased (by > 500%) in fibrotic regions and significantly, although less markedly, in regions without marked collagen deposition in myopathic hearts. Backscatter at 2.25 MHz was significantly increased (by > 600%) in fibrotic regions. Thus, alterations in acoustic properties occur in cardiomyopathic tissue, can be readily detected with reflected ultrasound, and provide a promising criteria for clinical diagnosis and characterization of evolution of cardiomyopathy due to Adriamycin and potentially other etiologies as well.

EMBOLIC POTENTIAL OF LEFT VENTRICULAR THROMBUS (LVT) DETECTED BY TWO-DIMENSIONAL ECHOCARDIOGRAPHY (2DE)

J. Mark Haugland, MD; Richard W. Asinger, MD; Frank L. Mikell, MD; K. Joseph Elsperger, CCPT; Morrison Hodges, MD, FACC. Hennepin County Medical Center and the University of Minnesota, Minneapolis, MN.

LVT is a frequent complication of acute myocardial infarction, congestive cardiomyopathy, and left ventricular aneurysm. Routine 2DE evaluation of such patients may reveal clinically unexpected thrombus, since embolic phenomena may not have occurred. In considering anticoagulation, it would be useful to determine if any 2DE characteristics of LVT are associated with embolization.

We reviewed clinical and echocardiographic features of 49 patients with LVT diagnosed by 2DE. Twelve of these 49 (24%) had evidence of peripheral embolization. Multiple 2DE characteristics were analyzed, and several were associated with a high risk of embolization: 14 patients had free intracavitary motion (FIM) of a thrombus margin, and 8 (57%) had emboli. Thirty patients had LVT which protruded into the left ventricular cavity, and 8 (26%) had emboli. In contrast, only 1 of 16 patients (6%) with a flat mural LVT and no FIM embolized. Four of 12 patients (33%) with an aneurysm distorting the diastolic contour of the left ventricle had evidence of embolization.

Clinical features also appeared helpful. Eight of 28 patients (24%) with recent (< 3 weeks) infarction had evidence of embolization in contrast to 2 of 23 patients (9%) with remote (> 3 weeks) myocardial infarction. Only 2 of our 49 patients had congestive cardiomyopathy, but both had embolic events.

We conclude that in addition to the clinical setting, certain 2DE features of LVT may be associated with embolization. LVT that protrude into the left ventricular cavity or demonstrate FIM have a high incidence of embolic events. These data may be helpful when considering anticoagulation therapy.

DYNAMIC INTRACAVITARY ECHOCARDIOGRAPHIC PATTERNS ASSOCIATED WITH LEFT VENTRICULAR MURAL THROMBI: CLINICAL AND EXPERIMENTAL OBSERVATIONS

Frank L. Mikell, MD; Richard W. Asinger, MD; K. Joseph Elsperger, CCPT; W. Robert Anderson, MD; Morrison Hodges, MD. Hennepin County Medical Center and the University of Minnesota, Minneapolis, MN.

Of 49 patients (pts) with left ventricular mural thrombi (LVMT) detected by two-dimensional echocardiography (2DE), 6 had associated unusual dynamic echos within the left ventricle. Five of these 6 pts had left ventricular aneurysm (LVA). These dynamic echos had 2 patterns: one pattern (Type 1) was characterized by low amplitude swirling echos with a slow, circular motion in the region of the apex (3 pts). These echos were not attached to the LVMT. The other pattern (Type 2) consisted of highly mobile, tail-shaped echo masses which were attached to the LVMT but which were less acoustically intense (4 pts). One patient had both types.

Similar echo patterns were observed with 2DE in 7 of 9 dogs with experimentally induced LVA and LVMT. In the dogs, both patterns frequently occurred together. In dogs with the Type 1 swirling echos without the tail-shaped masses, only liquid blood was found in addition to the LVMT at autopsy. In dogs with the discrete tail-shaped masses, autopsy inspection showed well-formed, bright red masses which were attached to the LVMT. These red tails could be distinguished from the endocardial portion of the LVMT. Histologically these tails consisted mainly of red blood cells enmeshed in a fine fibrin network.

We hypothesize that both intracavitary echo patterns are associated with LVMT and represent early stages of the intravascular coagulation process. The Type 1 pattern may represent aggregates of blood elements or sluggish blood flow within the ventricle. In contrast, the tail-shaped echos represent well-formed thrombi which have different gross and histologic characteristics than the endocardial LVMT.

EFFECTS OF COUPLING INTERVALS ON CONTRACTION PATTERNS OF PREMATURE BEATS DERIVED BY COMPUTER ASSISTED TWO-DIMENSIONAL ECHOCARDIOGRAPHY

Takahisa Uchiyama, MD; Eliot Corday, MD, FACC; Samuel Meerbaum, PhD, FACC; Tzu-Wang Lang, MD, FACC; Pascal Gueret, MD, FACC; Thomas Peter, MD, Cedars-Sinai Medical Center, Los Angeles, California

Phasic alterations in LV segmental wall motion during arrhythmias were studied by computer assisted two-dimensional echocardiography (2DE). In a short-axis cross-section at the mid-papillary level, the ventricular wall and luminal area were displayed in 8 individual segments around a geometric center. LV wall motions were mapped during premature ventricular contractions (PVC) over a wide range of coupling intervals (CI) in 7 closed chest dogs. Areas were computed in end-diastole and end-systole (interobserver variability 2.8 to 9.3%) and a % systolic area change (SAC) was analyzed for the entire tomographic section and its 8 segments. With CI=80% of sinus rhythm, SAC was normal in all segments except near the pacing site. Successive reduction of CI to 40% led first to uniform lowering of PVC-SAC and eventually to sharply disrupted sequence and pattern of segmental contraction. Postextrasystolic potentiation was enhanced as CI decreased. Section SAC (%) data (mean±SD) were:

Mean CI	PVC Beat (N=24)	Potentiated Beat (N=24)
Long (62%)	31.9±8.5*	70.5±4.5*§
Short (39%)	8.2±4.8*	80.8±5.8*§

*p<.001 vs Sinus-SAC (60.0±6.3%) §p<.001 vs PVC

Conclusion: During premature contractions as coupling intervals were progressively reduced, 2DE portrayed increasing disruption of LV geometry and segmental dynamics. Shorter PVC coupling intervals were associated with greater postextrasystolic potentiation. Computer assisted 2DE is capable of providing a comprehensive quantitative analysis of cardiac function during arrhythmias.

CORONARY CIRCULATION AND MYOCARDIAL BLOOD FLOW
2:00-3:30

ADRENERGIC TONE IN THE CANINE CORONARY CIRCULATION. Edward D. Verrier, MD, Gus J. Vlahakes, MD, Robert W. Baer, PhD, J. David Bristow, MD, FACC, Julien I.E. Hoffman, MD, FACC, FRCP. Cardiovasc. Res. Inst., U. of Calif., San Francisco.

Adrenergic tone may influence myocardial blood flow despite metabolic autoregulation. We examined this question in anesthetized dogs with a maximally vasodilated coronary circulation. Pressures were measured in the AO, LV, LA, and coronary sinus; heart rate was held constant by SA node block and atrial pacing (mean rate 115 min^{-1}). Diastolic coronary pressure-flow (P-Q) relations were determined with a circumflex preparation: coronary artery pressure was measured distal to a flow probe and occluder. Chromonar (8 $mg \cdot kg^{-1}$ iv) produced maximal coronary vasodilatation, confirmed by absence of reactive hyperemia. Twelve brief, partial occlusions were done at various distal pressures; mean diastolic coronary pressures and flows were used to construct a diastolic P-Q relation, which, with maximal vasodilatation, was linear [mean $r=0.98 \pm 0.01$ (SEM)]. P-Q lines were described by their slope and pressure intercept at zero flow. In 6 dogs, diastolic P-Q lines were determined before (Control) and after alpha blockade (AB) with phentolamine (5 mg iv). AO, LV, LA, and coronary sinus pressures did not change.

mean ± SEM	Control	AB	Analysis of variance
slope ($ml \cdot mm\ Hg \cdot min^{-1}$)	4.45 ± 0.51	4.37 ± 0.67	N.S.
intercept (mm Hg)	20.3 ± 0.4	17.9 ± 0.4	$P < 0.007$

AB produces a small, parallel, left shift in the P-Q line, which, with a large value for slope, increases diastolic coronary flow substantially at any given pressure during maximal vasodilatation. This suggests that alpha constrictor tone can limit myocardial blood flow despite maximal coronary vasodilatation and anesthesia.

In 4 other dogs, propranolol (0.25 $mg \cdot kg^{-1}$ iv) did not change either the slope or intercept of the diastolic P-Q line, suggesting that there is no significant resting beta tone in the canine coronary circulation under anesthesia.

BETA ADRENERGIC CONTROL OF LARGE CORONARY VESSELS IN CONSCIOUS DOGS

Pilar Macho, M.D. and Stephen F. Vatner, M.D., Dept. of Medicine, Harvard Medical School and Peter Bent Brigham Hospital, Boston, MA 02115

While β adrenergic regulation of the coronary circulation has been studied extensively, an important aspect of this topic, i.e., β effects on large coronary vessels has not been examined in the intact animal. To study this, 8 dogs were instrumented with miniature, piezoelectric crystals on opposing surfaces of the left circumflex coronary artery, an electromagnetic flow probe on the same vessel and miniature pressure gauges in the aorta and left ventricle. One week after surgery isoproterenol, 0.1 μg/kg/min, in conscious dogs increased mean left circumflex internal coronary cross sectional area (CSA) by 17 ± 3%, decreased late diastolic coronary resistance (LDCR) by 42 ± 5%, while increasing heart rate by 66 ± 8% and left ventricular (LV) dP/dt by 58 ± 5%. Atenolol, 1 mg/kg, a β_1 adrenergic selective blocker, reduced CSA by 8 ± 1%, and increased LDCR by 12 ± 4% ($p<0.01$). After atenolol, isoproterenol with heart rate constant did not increase LV dP/dt and caused significantly less, $p<0.01$, increases in CSA (6 ± 1%) and decreases in LDCR (11 ± 2%). On a separate day, propranolol, 0.5 mg/kg, reduced CSA by 7 ± 1%, while LDCR rose by 13 ± 4%, $p<0.05$. Isoproterenol after propranolol induced no effect. Thus, β adrenergic stimulation causes substantial increases in large coronary vessel CSA. Surprisingly, the major fraction of this response was associated with β_1 mediated increases in LV dP/dt and heart rate, whereas β_2 dilation of these vessels played a much lesser role. Moreover, β blockade resulted in significant constriction of large coronary vessels, an effect which could be detrimental in the presence of coronary artery disease, where large coronary vessel CSA is of crucial importance.

EFFECTS OF PROSTACYCLIN (PGI_2) ON CORONARY BLOOD FLOW IN OPEN-CHEST DOGS AFTER DIFFERENT ROUTES OF ADMINISTRATION

Volker B.Fiedler, DVM,PhD; Depts.Pharmacology, Cassella, Frankfurt, F.R.G., and University of Michigan,Ann Arbor

Prostacyclin (PGI2) is a potent vasodilator in isolated perfused hearts of various species. The in-vivo effects of PGI2 infusions were investigated in anesthetized,open-chest dogs. Coronary flow (CBF) was measured with an electromagnetic flow probe around the left circumflex artery (LCX), and coronary vascular resistance (CR) was calculated while aortic pressure (AOP) and heart rate (HR)were recorded.

Intravenous infusion of PGI2 (0.05 to 1.0 μg/kg/min) reduced AOP and CR in a dose-dependent fashion but had only minor effects on CBF. A tachycardia occurred parallel to the pressure reduction. However, when administered intracoronary distal to the flow probe PGI2 increased CBF 3-4 fold (p at least <0.05) and reduced CR ($p<0.05$) without affecting AOP and HR in doses between 0.05 to 0.5 μg. Topical application of PGI2 on the right ventricle increased coronary sinus oxygen content with minor changes in pressure. Cyclo-oxygenase inhibition (indomethacin, 5 mg/kg/min i.v.) did not alter the hypotensive effects of PGI2 after i.v. administration and increased the coronary vasodilator potency of the compound.

The sensitivity of the coronary vasculature seemes to be enhanced to PGI2 when endogenous biosynthesis of prostaglandin-like substanses is inhibited. Only after direct administration of PGI2 into the coronary circulation its specific coronary vasodilating effects can be demonstrated thus excluding the metabolization in the lung after intravenous application. It is suggested that PGI2 might be involved into the regulation of the coronary ciculation and coronary blood flow changes.

INFLUENCE OF NIFEDIPINE ON MYOCARDIAL BLOOD FLOW DURING THREE GRADES OF CORONARY OCCLUSION

William S. Weintraub, MD; Shigehiko Hattori, MD; Jai B. Agarwal, MD; Monty M. Bodenheimer, MD, FACC; Vidya S. Banka, MD, FACC; Richard H. Helfant, MD, FACC, Presbyterian-University of Pennsylvania Medical Center, Phila., Pa.

The effect of nifedipine (Nif) on myocardial blood flow (MBF) at varying grades of partial coronary occlusion (PO) is unknown. Thus 22 open chest dogs underwent carotid to left anterior descending perfusion with flow and perfusion pressure monitoring. Grades of coronary occlusion were defined by minimum diastolic perfusion pressure (DPP). After DPP was reduced to 54 mmHg (6 dogs), 37 mmHg (10 dogs) or 24 mmHg (6 dogs) 10 ug Nif was given intracoronary. Regional MBF in ml/g/min was determined by tracer microspheres. The three partial occlusions showed differing increases in total flow (%CF) and regional flow.

	Ischemic Zone MBF				Normal Zone MBF				
DPP	Endo		Epi		Endo		Epi		%CF
mmHg	PO	Nif	PO	Nif	PO	Nif	PO	Nif	
54	1.06	1.14	1.15	1.96*	1.29	1.28	1.11	1.10	42.3
37+	.70	.60*	1.06	1.39*	1.28	1.28	1.16	1.15	18.6+
24+	.48	.48	1.01	.94	1.54	1.49	1.60	1.57	-8.3+

*compared to control, +compared to above $p<.01$

At 54 mmHg Nif caused an increase in Epi MBF but no change in Endo MBF. In contrast at 37 mmHg Nif caused Epi flow to increase but resulted in a decrease in Endo flow. At the lowest perfusion pressure (24 mmHg) Nif caused no change in zone MBF. Thus the severity of coronary stenosis determines the presence of coronary vascular reserve in the endo and epicardium and thus the effect of nifedipine on regional myocardial perfusion. In certain settings, vasodilators such as nifedipine cause a redistribution or steal of flow from endocardium to epicardium.

LIMITED INFLUENCE OF CAPACITIVE EFFECTS ON CORONARY PRESSURE-FLOW RELATIONS AND ZERO-FLOW PRESSURES DETERMINED DURING SINGLE LONG DIASTOLES

James F. Klocke; David R. Kraus, BS; Irwin R. Weinstein, MD; Robert E. Mates, PhD; Francis J. Klocke, MD, FACC, State University of New York at Buffalo, New York

Bellamy's analysis of coronary pressure-flow relations during long diastoles indicates that coronary inflow normally ceases at a pressure >20 mm Hg. Eng and Kirk have suggested that measurements of epicardial inflow importantly underestimate capillary flow during long diastoles because of capacitive discharge of blood from precapillary vessels as inflow pressure falls. Accordingly, the left circumflex artery (LC) was cannulated in open-chest heart-blocked dogs and, using paired solenoids, perfused from either the aorta or a constant-pressure blood reservoir. The pressure-flow relation defined from single post-pacing diastoles during aortic perfusion was compared to the similar relation defined by points obtained by switching from aortic to reservoir perfusion at the onset of diastole over a wide range of reservoir pressures. Both relations were concave to the flow axis at lower LC pressures, and better fit by second-order than first-order equations. In eight animals with systolic pressures of 100-130 mm Hg, values for the curvilinear pressure-axis intercept ($P_{f=0}$) averaged 27 ± 5 (SD) mm Hg for variable-pressure aortic perfusion and 23 ± 4 mm Hg for constant-pressure reservoir perfusion ($p < 0.01$); differences in individual animals ranged from 3 to 7 mm Hg. Differences were smaller in similar studies during maximum vasodilation, $P_{f=0}$ being 12-15 mm Hg with both aortic and reservoir perfusion (but still higher than intracavitary diastolic pressures). Thus, the magnitude of capacitive discharge of blood during a long diastole appears insufficient to explain the differences between $P_{f=0}$ and RA and/or LV diastolic pressures now reported by several laboratories.

HOW DOES SYSTOLIC CORONARY ARTERY COMPRESSION CAUSE MYOCARDIAL ISCHEMIA IN DOGS?

Jacques R. Rouleau, MD, FACC; Jean-G. Dumesnil, MD; Louis Roy, MD; Gilles-R. Dagenais, MD, FACC, Quebec Heart Institute, Quebec, Canada.

The mechanism by which muscular coronary artery (CA) overbridging can cause ischemia is unclear since LV subendocardial blood flow is diastolic and CA compression systolic. To evaluate such a mechanism, we studied systolic compression (SC) of the proximal left circumflex CA in 10 anesthetized dogs both with autoregulation (A) and during maximal CA vasodilatation (V). Mechanical SC, triggered by ECG signal via a solenoid, was adjusted to interrupt CA flow only during the aortic ejection period. During control state and SC, we measured LV, AO and distal circumflex CA pressure (CP), phasic coronary blood flow proximal to SC, regional myocardial blood flow (RMBF) using 15 um diameter spheres, myocardial oxygen consumption (MVO_2) and myocardial lactate extraction (MLE). With SC, during A and V, there was a similar diastolic time lag to restart phasic CA blood flow (34±3 vs 31±3 msec) and to increase CP (69±4 vs 79±6 msec). With A, SC reduced the diastolic coronary:systolic LV pressure time ratio (DPTIc:SPTI)(1.09±0.10 vs $0.79\pm0.10^{+}$) and, due to effective A, RMBF was unchanged (101±10 vs 96±9 ml/min/100 g) as were the other measured variables. During V, SC decreased the circumflex vasodilatory reserve by 47% (439±61 vs 234±34 ml/min/100 g^{+}), the DPTIc:SPTI ratio (0.72±0.09 vs $0.55\pm0.07^{+}$), MVO_2 (14.2±2.2 vs 11.6±2.1 ml/min*) and MLE became negative; the inner:outer RMBF distribution was linearly related to the pressure ratio DPTIc:SPTI (r:80), independent of SC. Thus with maximal V and increased heart rate the diastolic time lag necessary to reopen the CA bed during SC becomes a limiting factor to myocardial perfusion. ($^{+}p<0.005$; $*p<0.05$)

VALUE OF MEASURING ANAEROBIC THRESHOLD DURING RADIONUCLIDE EXERCISE TESTING IN AORTIC REGURGITATION

Charles A. Boucher, M.D., FACC, David J. Kanarek, M.D., Harry R. Phillips, M.D., Richard R. Liberthson, M.D., Robert D. Okada, M.D., FACC, Peter C. Block, M.D., FACC, H. William Strauss, M.D., FACC, Gerald M. Pohost, M.D., FACC. Massachusetts General Hospital, Boston, MA.

The change (Δ) in ejection fraction (EF) from rest to peak exercise (ex) is being used to assess LV reserve in severe aortic regurgitation (AR). However, peak ex also reflects such factors as fitness and motivation. To standardize the approach to ex and to better understand the EF response, 11 catheterized normal and 26 AR patients with minimal or no symptoms underwent graded supine ex gated blood pool scans to peak tolerance. Oxygen uptake and ventilation were measured along with EF at each 3 min ex level. Anaerobic threshold (AT), which defines the earliest functional limitation during ex, was the ex level at which ventilation/oxygen uptake increased due to lactic acid production. EF at rest, AT and peak ex and the ΔEF before and after AT were compared. AR patients were divided based on the 2SD lower limit of ex capacity in normals: Group A with peak oxygen uptake >13 (17 patients) and Group B <13 ml/kg/min (9 patients). Mean ±1 SD values follow: (*p<.01)

Group	Rest EF	(ΔEF)	EF at AT	(ΔEF)	Peak EF
Normal	67±6%	(+6±6)*	73±5%*	(0±10)	73±10%*
A (AR)	62±7%*	(-1±4)*	61±10%*	(-5±5)	56±14%*
B (AR)	47±15%*	(-9±5)	38±13%	(-5±3)	33±13%

In AR, ΔEF with ex has 2 components based on AT. The first, ΔEF before AT, is related to functional reserve, whereas the second, ΔEF after AT, falls in all patients and is unrelated to functional reserve. These data suggest that ΔEF before AT provides adequate diagnostic information. Since AT is a submaximal and physiologic endpoint, ex beyond AT to peak tolerance is unnecessary.

RADIONUCLIDE ANGIOCARDIOGRAPHIC ASSESSMENT OF PATIENTS FOLLOWING REPAIR OF TRANSPOSITION OF THE GREAT ARTERIES

Roger A. Hurwitz, MD, FACC; Nicholas Papanicolaou, MD; Salvador Treves, MD; John F. Keane, MD; Aldo Castaneda, MD, FACC, Children's Hospital Medical Center, Boston, MA.

The utility of radionuclide angiocardiography (RAC) to detect the presence and progression of vena cava obstruction or residual left-to-right shunt was evaluated in patients 6 days to 3 years following surgical repair of transposition of the great arteries (TGA). Results of first pass RAC were compared to data obtained during cardiac catheterization (CC). Totally, 24/25 patients had good correlation between RAC and CC. Among 20 patients with clinical evidence of vena cava obstruction, early post-operative RAC and concurrent or subsequent CC excluded obstruction in 10. Significant obstruction was identified in 9 by both RAC and CC. In the remaining patient, obstruction was absent early post-operatively when evaluated by RAC, but was present 2 years later at CC. Among 5 patients with serial RAC and CC, satisfactory correlation was evident with either continued vena cava patency or progressive obstruction. All 5 patients with significant shunt (Qp:Qs > 1.5) measured at CC had almost identical flow ratios estimated by RAC. In another 4 patients, a questionable shunt at early post-operative RAC was absent at later CC. We conclude that following TGA repair, RAC is a valuable non-invasive method to identify (a) vena cava patency or obstruction, (b) progression of vena cava obstruction, and (c) significant residual shunts.

SERIAL RADIONUCLIDE ASSESSMENT OF DOXORUBICIN CARDIOTOXICITY IN CANCER PATIENTS WITH ABNORMAL BASELINE RESTING LEFT VENTRICULAR PERFORMANCE

William Choi, MD; Harvey Berger, MD; Jon Alexander, MD, FACC; Peter Schwartz, MD; Frans Wackers, MD, FACC; Barry Jaret, MD, FACC, Yale University School of Medicine and Yanbury Hospital; New Haven, Ct.

Previous studies from this laboratory have established guidelines for safe administration of doxorubicin to cancer patients (pts) with normal (nl) left ventricular (LV) performance. Over 36 months (mos), 48/329 pts (15%) referred for first-pass radionuclide evaluation of LV function had abnl (<55%) baseline resting LV ejection fraction (EF) prior to receiving doxorubicin. Thirty-one/48 pts had no evidence of antecedent heart disease. Sixteen/48 pts had received prior thoracic radiation therapy. Serial LVEF measurements were obtained over 2-15 mos of therapy in 29 pts. Of 18 pts not studied serially, 9 were denied doxorubicin because of abnl LVEF.

Initial LVEF averaged (±SD) 48±5% (range, 30-54%) in the 29 pts followed serially. After receiving 313±144 mg/M^2 (120-600 mg/M^2) of doxorubicin, final LVEF was unchanged (47±9%, pNS). In the 12 pts who received ≥350 mg/M^2, there also was no difference between initial and final values (48±8 vs 43±4%, pNS). LVEF declined by ≥10% in only 4 pts (12-18% EF units). One of these pts developed congestive heart failure (CHF) at 460 mg/M^2. No other pt developed CHF during therapy or long-term follow-up. Eleven/48 pts are still receiving doxorubicin in spite of abnl LVEF; the remaining 14 pts are either in remission or have died due to progression of disease.

Thus, abnl LV function is present in a substantial number of cancer pts without clinically evident antecedent heart disease. Doxorubicin can be administered safely in the presence of abnl baseline LV function using serial radionuclide studies as a means of monitoring therapy.

INDIUM-111 PLATELET SCINTIGRAPHY AND TWO DIMENSIONAL ECHOCARDIOGRAPHY IN THE DIAGNOSIS OF LEFT VENTRICULAR THROMBI

Michael D.Ezekowitz,MD,FACC; Don A.Wilson,MD; Eileen O. Smith,BS; Paul J.Kanaly,MD; Don E.Parker,PhD, University of Oklahoma Health Sciences Center, Oklahoma City, Okla.

The purpose of this study was to define the relative roles of these techniques in the diagnosis of mural thrombi (T) in patients (P) in whom the diagnosis could be surgically verified. Two groups of P were studied. Group I (n=19) consisted of P undergoing coronary artery bypass surgery with aneurysmectomy. Group II (n=8) were P undergoing mitral valve replacement and had non-significant coronary disease. All P had 2 dimensional echocardiograms (2DE); 18/19 in Group I and 8/8 in Group II had platelet scintigraphy (PS). Two DE images were obtained in parasternal long and short axis views and apical four chamber views and analyzed in real time, slow motion and stop action modes by 2 blinded observers. Each study was analyzed according to technical quality (excellent, adequate, poor) and probability of thrombus (positive, negative and possible). PS were analyzed by 2 observers in the LAO, RAO, L lateral and anterior views after injection of Indium-111 platelet suspension. Both observers graded 7/27 echos as excellent, 17/27 as adequate and 3/27 as poor; the latter category was not analyzed further. In Group I, 2DE had a sensitivity of 90% (both observers) and a specificity of 50% and 67% (observer 1 and 2). Both readers recorded 2 possibles which were negative at surgery. Observer agreement was 16/19 (84%). The sensitivity and specificity of PS was 80% and 100% (both observers). In Group II, all studies were true negatives by both techniques. It is concluded that: 1) 2DE appears more sensitive but less specific than PS. 2) 2DE identifies mass lesions while PS reflects 'haematological activity'. 3) The two techniques compliment each other.

DETECTION OF LEFT VENTRICULAR THROMBI BY RADIONUCLIDE ANGIOGRAPHY.

J.R. Stratton, M.D., J.L. Ritchie, M.D., K.E. Hammermeister, M.D., J.W. Kennedy, M.D., G.W. Hamilton, M.D. U. of Washington, Seattle, WA.

Filling defects compatible with left ventricular thrombi are occasionally noted on equilibrium radionuclide angiograms. To define the usefulness of this finding for the detection of LV thrombi, we blindly interpreted the anterior and left anterior oblique cineangiograms of 39 pts who had either proof of absence of thrombus (26 pts) by autopsy (24) or cardiac operation (2) or proof of presence of thrombus (13 pts) by autopsy (5), operation (2), or Indium-111 platelet imaging (6). Five pts with positive platelet imaging also had positive 2D echos for thrombus; the sixth pt did not have echo.

Overall, 13 angiograms were positive (10) or equivocally positive (3) for thrombus, and 26 were negative. Three studies were falsely positive and three falsely negative. Sensitivity of radionuclide angiography for detection of thrombus was 77% and specificity was 88%. All thrombi detected appeared on the anterior view as either a discrete apical filling defect (8 pts) or as a squared LV apex (2 pts). Two of 3 falsely positive studies had only LAO defects without anterior defects. Thirteen pts (8 with thrombus, 5 without) had 2D echos which were blindly and independently interpreted. Echo was 100% sensitive and specific in this small group. Risk factors for presence of thrombus included transmural anterior MI, LV aneurysm, and low ejection fraction. All 13 pts with thrombi had anterior MI vs. 7/26 (27%) of pts without thrombi ($p<.01$). Nine of 13 pts (69%) with thrombi had aneurysms vs. 7/26 (27%) of pts without thrombi ($p = .02$). Mean ejection fraction in pts with thrombi was .29 vs. .41 in pts without thrombi ($p = .05$). Six of 13 pts (46%) with thrombi had systemic emboli vs. 1/26 (4%) of pts without thrombi ($p < .01$).

The finding of a discrete filling defect or squared LV apex on radionuclide angiography is a useful clue to the presence of a LV thrombus, which can be confirmed by other noninvasive studies.

RADIONUCLIDE VENTRICULOGRAPHY FOLLOWING RESUSCITATION FROM OUT-OF-HOSPITAL VENTRICULAR FIBRILLATION

Gene B. Trobaugh, MD; Brian W. Gross, MD; Jeffrey A. Werner, MD, FACC; H. Leon Greene, MD, FACC; Gary Caputo, MD; Glen W. Hamilton, MD, FACC; Leonard A. Cobb, MD, FACC, Harborview Medical Center, Seattle, Wa.

Thirty-four patients (pts) who survived initial resuscitation from out-of-hospital ventricular fibrillation (VF) without isoenzyme evidence for necrosis had a radionuclide ventriculogram (RNV) within 12 hours after VF. Studies were repeated 1 week later in 24 pts. The left ventricular wall motion was visually assessed by independent two observers.

On admission, the mean LVEF was 36%± 18% (±1S.D.) and ranged from 8% to 71%. The most abnormal of the six wall segments was normal or slightly hypokinetic in 7 (21%), moderately hypokinetic in 2 (6%), severely hypokinetic in 10 (29%), akinetic in 5 (15%) and dyskinetic in 10 (29%). The average number of wall segments which manifested severe hypokinesis, akinesis, or akinesis was 2.4 ± 2.1.

The admission LVEF was lower in those who died (n=10) during hospitalization than those lived to be discharged (n=24) (29%± 19% vs. 39%±17%, p=.05). Those who died also had more segments with severe hypokinesis (or worse) contractility (3.5± 2.0 vs. 1.9±2.0, p<.001).

In the 24 pts who also had a RNV performed a week later, the LVEF increased by 16%±12% ($p< .001$) and the average number of wall segments with severe hypokinesis (or worse) decreased by 1.9 ± 1.4 ($p < .001$).

Following out-of-hospital VF in those without necrosis, there is an overall increase in LVEF and improved contractility during the first week of hospitalization in those who lived to be discharged. The admission LVEF was significantly lower and contractility was worse in those who died.

THE VENTRICLES III: MEMBRANE ACTION POTENTIAL STUDIES
4:00-5:00

EFFECT OF ISOPROTERENOL ON "RESIDUAL FAST CHANNEL-DEPENDENT SLOW CONDUCTION" PRODUCED IN GUINEA PIG VENTRICULAR MUSCLE

Makoto Arita, MD, FACC; Tatsuto Kiyosue, Department of Physiology, Medical College of Oita, Oita 879-56, Japan

We studied the effect of isoproterenol (ISP) on upstroke and duration of action potentials (AP's) and conduction velocity in incompletely depolarized ventricular papillary muscle whose resting potential was -57 ± 2 mV in high K^+ (14 mM)-Tyrode solution with microelectrodes. Without ISP, the AP upstroke had a slur and the maximum rate of rise ($\dot{V}$ max) was made of 2 components: the first large (13 - 27 V/s) and the second small (less than 8 V/s) ones (split $\dot{V}$ max). The conduction velocity was less than about 30 cm/s ("slow conduction"). The first $\dot{V}$ max was depressed by TTX (10^{-6} M) and the second, by l-verapamil (1 µg/ml) indicating that the impulses were transmitted via the first one, i.e., "residual fast channel". The recovery of excitability measured using $\dot{V}$ max of premature AP's with basic rate of 0.1 Hz revealed a rapid (τ= 40.6 ± 3.5 ms) followed by a slow (τ= 533.3 ± 48.3 ms) recovery process. No rate-dependent change in AP duration and refractory period was found among rates 0.1, 0.5 and 0.9 Hz tested. ISP (5 x 10^{-7} M) selectively increased and approximately quadrupled the second component of the split $\dot{V}$ max overcoming the first. ISP produced marked rate-dependent shortening of AP duration, being maximum at 0.1 Hz (226 ± 17 ms) and minimum at 0.9 Hz (149 ± 16 ms) with significant shortening of post repolarization refractoriness, but produced no change in recovery kinetics of $\dot{V}$ max. The results suggest that "residual fast channel" could produce "slow conduction" without ISP and that main ionic channels (fast and slow) responsible for some slow conduction in reentry may alternate according to local concentration of tissue catecholamines.

STABILIZING EFFECT OF INSULIN ON AUTOMATICITY IN PARTIALLY DEPOLARIZED CARDIAC PURKINJE FIBERS

Joseph Reiser, Ph.D., Gary J. Anderson, MD., FACC, John Swartz.Hahnemann Medical College & Hospital,William Likoff Cardiovascular Institute, Philadelphia, Pennsylvania

The purpose of this study was to evaluate the effect of insulin (I) on automaticity (Au) and membrane potential (MP) of cardiac Purkinje fibers showing low MPs.Existing depressed fibers and stretched-induced depolarized tissue was studied utilizing standard microelectrode techniques. In 8 experiments,I (.048 µ/cc) induced the following electrophysiologic effects after 40 min exposure:

Control	MDP(mV)	APA(mV)	(IR(b/min)	dE/dt(mV/s)
(Mean±SE)	68.56	50.65	41.51	12.63
	±4.3	±7.9	±6.7	±2.1
Insulin				
(Mean±SE)	87.7	85.4	24.5	6.6
	±1.9	±6.1	±5.1	±1.0
P	<.01	<.01	<.01	<.01

MDP-Maximum Diastolic Potential,APA-Action Potential Amplitude, IR-Intrinsic Rate,dE/dt-ph 4 slope.
In contrast, spontaneous fibers showing normal MPs showed insignificant effects after a similar time period of I exposure.I given before or after epinephrine (10^{-7}-5 x 10^{-6}M) did not affect the rate of epinephrine-induced Au or the MP (n=7,p=NS).These results suggests that I exerts a direct effect on the cell membrane which is primarily manifest as an increase in the MP. The stabilizing effect on Au is related to improved MP. Since this effect does not occur in fully polarized cells,these data suggest that either Na,K pump activity or membrane conductance is impaired in depolarized cells.This concept is supported by the failure of I to effect normal cells or cells exposed to epinephrine, where pump activity and potassium conductance are optimized.Thus,I through its stabilizing effect on the cell membrane may be antiarrhythmic.

SITE OF ACTION OF LOCAL ANESTHETICS ON HEART FIBERS

Lawrence H. Frame, MD., Gary A. Gintant and Brian F. Hoffman, MD, FACC. Columbia University, New York, N.Y.

For nerve and muscle there is evidence that the charged form of lidocaine interacts during stimulation with the fast inward channel from the inner surface of the membrane and that a period of quiescence causes partial recovery from block of I_{Na}. We have used QX-314 (QX) ((N-(2,6-dimethylphenyl)-carbamoylmethyl)triethylammonium bromide), a quaternary derivative of lidocaine, to evaluate this question for canine Purkinje fibers (PF). Block of fast channels was quantified by measuring $\dot{V}$max of phase 0 of the action potential (AP) recorded using intracellular microelectrodes. Superfusion with Tyrode solution (K^+=2.7 or 4.0mM) containing QX (1-4x10^{-3}M) slowly decreased $\dot{V}$max of the stimulated AP (cycle length = 1 sec) by 30-60%. After quiescence, the $\dot{V}$max of the first AP equaled the drug free value of $\dot{V}$max. The $\dot{V}$max of subsequent AP's during regular stimulation rapidly decreased to the reduced value recorded prior to quiescence. All of these phenomena persisted after returning to superfusion with drug free Tyrode solution. In separate experiments intracellular injection of QX during superfusion with drug free Tyrode solution produced a rapid reduction of $\dot{V}$max to 30-60% of control at the site of injection. After 2-5 minutes of quiescence the $\dot{V}$max of the first AP approached the control value and then again decreased during stimulation to the same level that preceeded quiescence. This recovery of $\dot{V}$max during quiescence probably is due to dissociation of QX from fast channels. The subsequent decrease to the same depressed value of $\dot{V}$max that preceeded quiescence suggests that the dissociated QX was confined intracellularly. These findings indicate that QX interacts with fast channels from the inner surface of the sarcolemma and also that PF are permeable to charged local anesthetic molecules.

NIFEDIPINE BUT NOT VERAPAMIL HAS AGE-INDEPENDENT EFFECTS ON CARDIAC REPOLARIZATION.

Alan M. Ezrin, Ph.D., Agustin Ramos, M.D., Angel Leon, B.S., Arthur L. Bassett, Ph.D., Henry Gelband, M.D., FACC. Univ. of Miami, Miami, Fla.

The Ca^{2+}-antagonists verapamil and nifedipine reportedly affect myocardial repolarization (Q-T interval) differently. This study delineates the cellular mechanism underlying the effects of these drugs on Purkinje fiber (PF) repolarization in adult and neonatal hearts. Activation of K^+-repolarizing channels in adult PF is modulated by Ca_i^{2+} (Isenberg, G. Pflug. Arch. 371:61-69, 1977), and is delayed by exposure to verapamil or low Ca_o^{2+}. However, repolarization of neonatal PF is not delayed by verapamil or low Ca_o^{2+}. This suggests that changes in Ca_i^{2+} do not influence K^+-repolarizing channels in the immature heart. Newborn (1-9 days) and adult rabbit PF were isolated and action potentials (AP) were monitored using standard microelectrode techniques (36° C; BCL = 630 msec). Phase 2 duration (AP plateau) in both age groups was shortened by verapamil (2 µM) or nifedipine (0.1 - 2 µM), whereas their effects upon repolarization differed. Verapamil increased AP duration (APD_{90}), effective refractory period (ERP) and prolonged phase 3 (terminal repolarization) in adult PF. Nifedipine decreased APD_{90} and ERP, while phase 3 was unaffected. In contrast, both drugs decreased phase 2 duration, APD_{90} and ERP in neonatal PF. Verapamil (2 µM) and nifedipine (0.1 - 2 µM) abolished high K^+ (20 mM) induced slow responses generated by adult and neonatal PF. Our data demonstrate an age-independent effect of nifedipine upon repolarization. We suggest that nifedipine shortens APD in adult PF by decreasing the inward Ca^{2+} current. In contrast to verapamil, attenuation of the slow inward current by nifedipine is unrelated to Ca_i^{2+} control of K^+ repolarizing channels in adult hearts.

PACING AND TACHYCARDIA
1:00-5:00

TWO YEARS' CLINICAL EXPERIENCE WITH A SELF-SEARCHING TACHYCARDIA PACEMAKER

Edgar Sowton, MD, FRCP, FACC; Håkan Elmqvist, Christer Hård af Segerstad, Guy's Hospital, London, England.

5 patients with reciprocating tachycardia have been treated with a pacemaker which automatically identifies the correct timing to terminate attacks with ectopic beats. This is done by successive approximation with earlier or later adjustment of the timing by a microprocessor according to the electrophysiological response to the last stimulus. Timing steps become progressively smaller allowing stimulation even in extremely narrow windows of a few milliseconds duration. Double stimuli are automatically delivered if 6 attempts with single stimuli fail to terminate tachycardia, and successful timing is remembered for the first stimulus during the next episode of tachycardia.

5 patients have been treated over 2 years with one version of this apparatus which activates an implanted stimulator via skin impulses. 4 patients have WPW, 3 AV nodal tachycardia and 1 VT. Attacks occurred up to 10 times a day and have all been terminated by critically timed stimuli. In most patients the left-hand edge of the termination window is constant within 10 mseconds and attacks are then terminated by the first or second stimulus; standing up or exercise contracts the window usually by advancing its right-hand (late) limit. The pacemaker has identified these changes, as well as those produced by beta blockers, disopyramide, quinidine or verapamil and has terminated tachycardias with most episodes requiring less than 3 steps.

AUTOMATIC CYCLE LENGTH ADJUSTMENT-A VERSATILE PACEMAKER FOR TACHYCARDIA TERMINATION

Anthony Nathan,MB;Kevin Hellestrand,MB;John Camm,MB; Goworth Spurrell,MD,FACC.
St.Bartholomew's Hospital,London,England.

When overdrive pacemakers(PM) fail to terminate tachycardia(T), frequent futile repititions of the same pacing sequence usually occur. A new PM is described in which failure to terminate T leads to a reduction in pacing cycle length by 6 msec before termination is reattempted, a process that may be repeated upto a maximum of 16 times. This PM is capable of delivering a preset number of stimuli(1 to 15) in response to a T defined as 4 successive beats occuring at a rate faster than a preset value. The initial coupling interval and subsequent pacing cycle intervals are always equal.After successful conversion a further episode of T evokes the previously successful pacing sequence.A bradycardia standby function is incorporated.

The system was evaluated in 15 consecutive patients with recurrent supraventricular T(11 atrioventricular,4 intranodal) during electrophysiological study. T cycle length ranged from 245-450(mean 363)msec.Right ventricular bipolar pacing was successful in all patients.1 stimulus terminated T in 5 patients, 2 stimuli were effective in a further 8, and 2 required 5 and 6 stimuli.No unwanted arrhythmias were induced.

This PM has proved clinically valuable for the repeated termination of recurrent spontaneous T, as well as for T induced at electrophysiological study.The non-competitive nature of this mode of pacing reduces the likelihood of provoking unwanted arrhythmias, but the theoretical risks associated with rapid bursts of ventricular pacing require further evaluation.

BENEFITS AND RISKS OF COMBINED BURST PACING AND DRUG THERAPY OF RECURRENT VENTRICULAR TACHYCARDIA.

H.J. Duff, M.D., S. Reele, M.D., D.M. Roden, M.D., E.L. Carey, M.D., J.W. Hammon, M.D., R.L. Woosley, M.D.,Ph.D. and R.F. Smith, M.D., FACC. Departments of Pharmacology and Medicine, Vanderbilt University School of Medicine, Nashville, TN.

As a possible aid in the management of recurrent sustained ventricular tachycardia (VT), a radio frequency-energized and manually-controlled Medtronic 5998 pacemaker (VP) with a transvenous ventricular electrode was implanted in 6 patients (pts) whose VT was partially controlled by drugs and who required repeated cardioversions. The effectiveness of asynchronous bursts of rapid ventricular pacing was established in all pts prior to VP implantation. Drug therapy was continued in 5/6 pts after VP implantation. The 6 pts have been followed for a mean of 9 months (range 1-18 mo.). One pt, an alcoholic who refused additional therapy, died suddenly. Surviving pts have continued to require conversion by VP; recurrence rates range from 1/yr. - 48/yr. In each case, the pt was instructed to report to a hospital when VT occurs and was carefully monitored when conversion was done. VP has been successful in all episodes but adjustments in VP rate were required in 3/6 pts. The rate adjustment of the Medtronic 5998 unit is not accurately calibrated and on 2 occasions, VP was inadvertently set at greater than 300 BPM causing ventricular fibrillation in 1 pt. The rate of the VP unit can be checked externally by counting audible clicks on an AM radio placed next to the radio frequency unit. Conclusion: VP provides an alternative method of terminating VT and when used with drug therapy, aids in pt. management. Rate adjustments are frequently necessary and excessive ventricular rates may cause ventricular fibrillation. Therefore, pts should be monitored during conversions and a defibrillator should be readily available.

LONG-TERM EFFECTIVENESS OF DUAL-DEMAND SEQUENTIAL PACING FOR AUTOMATIC CONVERSION AND PREVENTION OF REFRACTORY REENTRY SUPRAVENTRICULAR TACHYCARDIA

James D. Maloney, MD, FACC; Victor Medina-Ravell, MD; Otto Hernandez Pieretti, MD; Bohvar Portillo, MD; Castor Maduro, MD; Barouh Berkovits, FACC; Federico Moleiro, MD, Mayo Clinic, Rochester, Minnesota, and Universidades Central and Zulia of Venezuela, Valencia, Venezuela

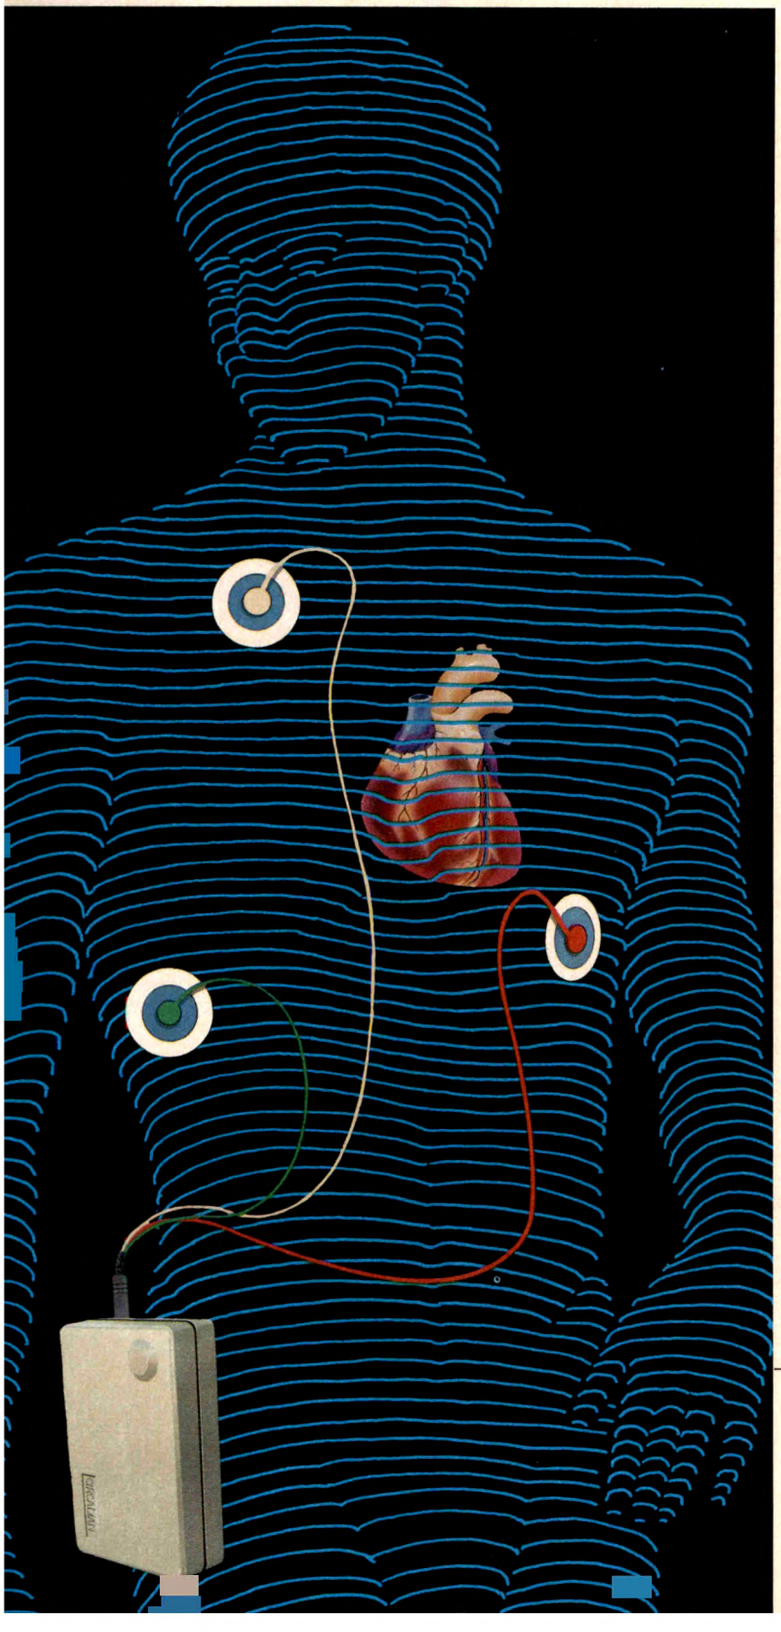
Eight patients (pts) with refractory symptomatic paroxysmal supraventricular tachycardia (PSVT) received dual-demand atrioventricular sequential pacemakers--5992DD--(DDS) for control and automatic underdrive conversion of PSVT. All had recurrent syncope and were symptomatic for 6 to 40 years. Paroxysmal atrial fibrillation (PAF) with antegrade conduction occurred in 3. Ventricular fibrillation was observed in 1.

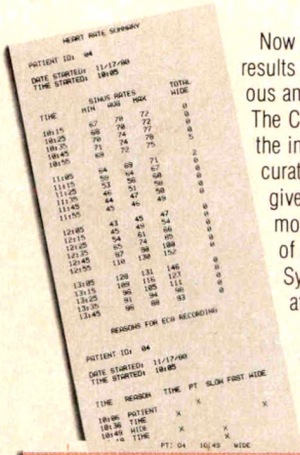
Pre- and post-DDS assessment included Holter monitoring and regular follow-up visits. His bundle studies with programmed electrical stimulation documented PSVT mechanism and effectiveness of DDS underdrive conversion in acute settings. PSVT mechanism included 3 pts with WPW-A, 1 patient with WPW-septal, 2 pts with WPW-B, and 2 pts with AV nodal reentrance.

Follow-up observations for 6 to 20 months demonstrated continuing effectiveness of DDS in recognizing and converting spontaneous PSVT. In 2 pts, PSVT has been totally prevented and the frequency and duration of PSVT markedly reduced in 4. Concurrent drugs were reduced or eliminated in all. Pacemaker complications have not been observed.

Chronic effectiveness of DDS for prevention and conversion of PSVT in selected pts is demonstrated. PAF is not a contraindication.

CircaMed. Simple. Affordable. State of the art.





Now you can have all the relevant results of up to three days continuous ambulatory ECG monitoring. The CircaMed System summarizes the information into a short, accurate, complete printout that gives you the benefit of days of monitoring with only minutes of your time. The CircaMed System is simple to use, and affordable.

The CircaMed Monitor is an ambulatory ECG recorder and cardiac rate monitor. Microcomputer controlled, it captures and stores 144 heart rate summaries per day.

When the monitor detects an abnormally high or low rate, or an unusually wide beat, a ten second tape recording of the ECG is activated. The patient may also activate a recording; the system will record at least one ten second ECG every thirty minutes. The time and reason for each recording are stored in memory.

The Central Control Module translates Monitor information into a print-out of each heart rate summary, plus a print-out of time and reason for each ECG recorded.

The Chart Recorder Module provides a chart print-out for the taped ECG measurements, annotated with patient number, recording time, and reason for recording.

The CircaMed System is designed and priced for your office, yet it delivers the sophisticated capabilities of a large hospital system.

Fill in the coupon and we'll be glad to show you just how easy state of the art ECG monitoring can be.

CIRCADIAN

[illegible]® (propranolol HCl) works, the anginal heart doesn't have to work so hard.

Consider the anginal heart at stress: It works harder, faster. Needs more oxygen. Pumps harder, faster still. Strives for more oxygen—with pain. Anginal attack means more nitroglycerin. And that means faster heart rate. The cycle repeats.

Consider Inderal: It reduces heart rate—therapeutically—by some 12 beats a minute.[1-6] 720 fewer beats per hour. Some 6 million fewer beats per year. That means less work for the anginal heart. Less oxygen demand by the myocardium. Fewer anginal attacks. Less need for sublingual nitroglycerin. More tolerance for exercise—and more freedom of action.

Reduction in heart rate is modest: should not be cause for concern.[7] The relatively low dosages required for angina prophylaxis (an average of 160 mg/day) produce few, if any, serious adverse reactions, which in any case are readily recognized and controlled.

With proper patient selection—in the absence of bronchial asthma, sinus bradycardia, or heart block greater than first degree—risk of precipitating cardiac failure is extremely rare. And withdrawal problems may be avoided by reducing dosage gradually—rather than abruptly.*

Consider too: There is also a favorable redistribution of perfusion to the vulnerable subendocardium.[8] And, in patients who may still need nitroglycerin p.r.n., INDERAL will cancel the undesirable increase in heart rate and contractility.

Prescribe INDERAL with confidence. Effective. Reliable. For patients with moderate to severe angina in whom conventional measures have failed.

For full information on Contraindications, Precautions, Adverse Reactions, and Warnings, including avoidance of abrupt withdrawal, please consult the prescribing information on the following page.

INDERAL® (PROPRANOLOL HCl)
TODAY'S 40mg 80mg tabs.
BENCHMARK FOR ANGINA PROPHYLAXIS

Ayerst®

BRIEF SUMMARY
(FOR FULL PRESCRIBING INFORMATION, SEE PACKAGE CIRCULAR.)
Inderal® BRAND OF
PROPRANOLOL HYDROCHLORIDE
A beta-adrenergic blocking agent

BEFORE USING INDERAL (PROPRANOLOL HYDROCHLORIDE), THE PHYSICIAN SHOULD BE THOROUGHLY FAMILIAR WITH THE BASIC CONCEPT OF ADRENERGIC RECEPTORS (ALPHA AND BETA), AND THE PHARMACOLOGY OF THIS DRUG.

ACTIONS

Beta receptor blockade is useful in conditions in which, because of pathologic or functional changes, sympathetic activity is excessive or inappropriate and detrimental to the patient. But there are also situations in which sympathetic stimulation is vital. For example, in patients with severely damaged hearts, adequate ventricular function is maintained by virtue of sympathetic drive which should be preserved. In the presence of AV block, beta blockade may prevent the necessary facilitating effect of sympathetic activity on conduction. Beta blockade results in bronchial constriction by interfering with adrenergic bronchodilator activity which should be preserved in patients subject to bronchospasm.

The proper objective of beta blockade therapy is to decrease adverse sympathetic stimulation but not to the degree that may impair necessary sympathetic support.

Propranolol may reduce the oxygen requirement of the heart at any given level of effort by blocking catecholamine-induced increases in heart rate, systolic blood pressure, and the velocity and extent of myocardial contraction. On the other hand, propranolol may increase oxygen requirements by increasing left ventricular fiber length, end diastolic pressure, and systolic ejection period.

If the net physiologic effect of beta adrenergic blockade in angina is advantageous, it would be expected to manifest itself during exercise by delayed onset of pain due to decreased oxygen requirement.

INDICATION

Angina Pectoris Due to Coronary Atherosclerosis: The initial treatment of angina pectoris involves weight control, rest, cessation of smoking, use of sublingual nitroglycerin, and avoidance of precipitating circumstances. INDERAL is indicated in selected patients with moderate to severe angina pectoris who have not responded to these conventional measures. Propranolol should not be used in patients with angina which occurs only with considerable effort or with infrequent precipitating factors.

INDERAL exerts both favorable and unfavorable effects, the preponderance of which may be beneficial. (See ACTIONS Section.) INDERAL should not be continued unless there is reduced pain or increased work capacity.

Because of the potential for adverse results, treatment should be carefully monitored. The patient should also be reevaluated periodically since the dosage requirement and the need to continue INDERAL may be altered by clinical exacerbations or remissions. (See DOSAGE AND ADMINISTRATION.)

Additional studies of the effects of INDERAL in angina pectoris patients are in progress to better evaluate and define the proper role of INDERAL in this condition.

CONTRAINDICATIONS

INDERAL is contraindicated in: 1) bronchial asthma; 2) allergic rhinitis during the pollen season; 3) sinus bradycardia and greater than first degree block; 4) cardiogenic shock; 5) right ventricular failure secondary to pulmonary hypertension; 6) congestive heart failure (see WARNINGS) unless the failure is secondary to a tachyarrhythmia treatable with INDERAL; 7) in patients on adrenergic-augmenting psychotropic drugs (including MAO inhibitors), and during the two week withdrawal period from such drugs.

WARNINGS

CARDIAC FAILURE: Sympathetic stimulation is a vital component supporting circulatory function in congestive heart failure, and inhibition with beta-blockade always carries the potential hazard of further depressing myocardial contractility and precipitating cardiac failure. INDERAL acts selectively without abolishing the inotropic action of digitalis on the heart muscle (*i.e.*, that of supporting the strength of myocardial contractions). In patients already receiving digitalis, the positive inotropic action of digitalis may be reduced by INDERAL's negative inotropic effect. The effects of INDERAL and digitalis are additive in depressing AV conduction.

IN PATIENTS WITHOUT A HISTORY OF CARDIAC FAILURE, continued depression of the myocardium over a period of time can, in some cases, lead to cardiac failure. In rare instances, this has been observed during INDERAL therapy. Therefore, at the first sign or symptom of impending cardiac failure, patients should be fully digitalized and/or given a diuretic, and the response observed closely: a) if cardiac failure continues, despite adequate digitalization and diuretic therapy, INDERAL therapy should be immediately withdrawn; b) if tachyarrhythmia is being controlled, patients should be maintained on combined therapy and the patient closely followed until threat of cardiac failure is over.

IN PATIENTS WITH ANGINA PECTORIS, there have been reports of exacerbation of angina and, in some cases, myocardial infarction, following *abrupt* discontinuation of INDERAL therapy. Therefore, when discontinuance of INDERAL is planned the dosage should be gradually reduced and the patient carefully monitored. In addition, when INDERAL is prescribed for angina pectoris, the patient should be cautioned against interruption or cessation of therapy without the physician's advice. If INDERAL therapy is interrupted and exacerbation of angina occurs, it usually is advisable to reinstitute INDERAL therapy and take other measures appropriate for the management of unstable angina pectoris. Since coronary artery disease may be unrecognized, it may be prudent to follow the above advice in patients considered at risk of having occult atherosclerotic heart disease, who are given propranolol for other indications.

IN PATIENTS WITH THYROTOXICOSIS, possible deleterious effects from long term use have not been adequately appraised. Special consideration should be given to propranolol's potential for aggravating congestive heart failure. Propranolol may mask the clinical signs of developing or continuing hyperthyroidism or complications and give a false impression of improvement. Therefore, abrupt withdrawal of propranolol may be followed by an exacerbation of symptoms of hyperthyroidism, including thyroid storm. This is another reason for withdrawing propranolol slowly. Propranolol does not distort thyroid function tests.

IN PATIENTS WITH WOLFF-PARKINSON-WHITE SYNDROME, several cases have been reported in which, after propranolol, the tachycardia was replaced by a severe bradycardia requiring a demand pacemaker. In one case this resulted after an initial dose of 5 mg propranolol.

IN PATIENTS DURING ANESTHESIA with agents that require catecholamine release for maintenance of adequate cardiac function, beta blockade will impair the desired inotropic effect. Therefore, INDERAL should be titrated carefully when administered for arrhythmias occurring during anesthesia.

IN PATIENTS UNDERGOING MAJOR SURGERY, beta blockade impairs the ability of the heart to respond to reflex stimuli. For this reason, with the exception of pheochromocytoma, INDERAL should be withdrawn 48 hours prior to surgery, at which time all chemical and physiologic effects are gone according to available evidence. However, in case of emergency surgery, since INDERAL is a competitive inhibitor of beta receptor agonists, its effects can be reversed by administration of such agents, *e.g.*, isoproterenol or levarterenol. However, such patients may be subject to protracted severe hypotension. Difficulty in restarting and maintaining the heart beat has also been reported.

IN PATIENTS PRONE TO NONALLERGIC BRONCHOSPASM (*e.g.*, CHRONIC BRONC EMPHYSEMA), INDERAL should be administered with caution since it may block bronch tion produced by endogenous and exogenous catecholamine stimulation of beta recept

DIABETICS AND PATIENTS SUBJECT TO HYPOGLYCEMIA: Because of its beta-adre blocking activity, INDERAL may prevent the appearance of premonitory signs and symp (pulse rate and pressure changes) of acute hypoglycemia. This is especially important t in mind in patients with labile diabetes. Hypoglycemic attacks may be accompanied by cipitous elevation of blood pressure.

USE IN PREGNANCY: The safe use of INDERAL in human pregnancy has not been es tablished. Use of any drug in pregnancy or women of childbearing potential requires tha possible risk to mother and/or fetus be weighed against the expected therapeutic benef bryotoxic effects have been seen in animal studies at doses about 10 times the maximum ommended human dose.

PRECAUTIONS

Patients receiving catecholamine depleting drugs such as reserpine should be closely o served if INDERAL is administered. The added catecholamine blocking action of this dru then produce an excessive reduction of the resting sympathetic nervous activity. Occasi the pharmacologic activity of INDERAL may produce hypotension and/or marked brady resulting in vertigo, syncopal attacks, or orthostatic hypotension.

As with any new drug given over prolonged periods, laboratory parameters should be served at regular intervals. The drug should be used with caution in patients with impaire or hepatic function.

ADVERSE REACTIONS

Cardiovascular: bradycardia; congestive heart failure; intensification of AV block; hypote paresthesia of hands; arterial insufficiency, usually of the Raynaud type; thrombocytoper purpura

Central Nervous System: lightheadedness; mental depression manifested by insomni tude, weakness, fatigue; reversible mental depression progressing to catatonia; visual d bances; hallucinations; an acute reversible syndrome characterized by disorientation for and place, short term memory loss, emotional lability, slightly clouded sensorium, and de creased performance on neuropsychometrics

Gastrointestinal: nausea, vomiting, epigastric distress, abdominal cramping, diarrhea, stipation, mesenteric arterial thrombosis, ischemic colitis

Allergic: pharyngitis and agranulocytosis, erythematous rash, fever combined with ac and sore throat, laryngospasm and respiratory distress

Respiratory: bronchospasm

Hematologic: agranulocytosis, nonthrombocytopenic purpura, thrombocytopenic purp

Miscellaneous: reversible alopecia. Oculomucocutaneous reactions involving the skin, ous membranes and conjunctivae reported for a beta blocker (practolol) have not been c sively associated with propranolol.

Clinical Laboratory Test Findings: Elevated blood urea levels in patients with severe he ease, elevated serum transaminase, alkaline phosphatase, lactate dehydrogenase

DOSAGE AND ADMINISTRATION

The dosage range for INDERAL is different for each indication.

ORAL

ANGINA PECTORIS—*Dosage must be individualized.* Starting with 10-20 mg three or f times daily, before meals and at bedtime, dosage should be gradually increased at three seven day intervals until optimum response is obtained. Although individual patients may spond at any dosage level, the average optimum dosage appears to be 160 mg per day. angina pectoris, the value and safety of dosage exceeding 320 mg per day have not bee established.

If treatment is to be discontinued, reduce dosage gradually over a period of several we (See WARNINGS.)

PEDIATRIC DOSAGE

At this time the data on the use of the drug in this age group are too limited to permit ad quate directions for use.

OVERDOSAGE OR EXAGGERATED RESPONSE

IN THE EVENT OF OVERDOSAGE OR EXAGGERATED RESPONSE, THE FOLLOWING SURES SHOULD BE EMPLOYED:

BRADYCARDIA—ADMINISTER ATROPINE (0.25 to 1.0 mg): IF THERE IS NO RESPO TO VAGAL BLOCKADE, ADMINISTER ISOPROTERENOL CAUTIOUSLY

CARDIAC FAILURE—DIGITALIZATION AND DIURETICS

HYPOTENSION—VASOPRESSORS, *e.g.*, LEVARTERENOL OR EPINEPHRINE (THER EVIDENCE THAT EPINEPHRINE IS THE DRUG OF CHOICE)

BRONCHOSPASM—ADMINISTER ISOPROTERENOL AND AMINOPHYLLINE

HOW SUPPLIED

INDERAL

TABLETS (propranolol hydrochloride)

No. 461—Each scored tablet contains 10 mg of propranolol hydrochloride, in bottles of 1(1,000. Also in unit dose package of 100.

No. 462—Each scored tablet contains 20 mg of propranolol hydrochloride, in bottles of 1(1,000. Also in unit dose package of 100.

No. 464—Each scored tablet contains 40 mg of propranolol hydrochloride, in bottles of 1(1,000. Also in unit dose package of 100.

No. 468—Each scored tablet contains 80 mg of propranolol hydrochloride, in bottles of 1(1,000. Also in unit dose package of 100.

INJECTABLE

No. 3265—Each ml contains 1 mg of propranolol hydrochloride in Water for Injection. The adjusted with citric acid. Supplied as: 1 ml ampuls in boxes of 10.

EFFECTS OF BEDREST DECONDITIONING ON EXERCISE VENTRICULAR FUNCTION IN MIDDLE-AGED MEN

Joseph Hung, MD, Danielle Goldwater, MD, Victor Convertino, James McKillop, MD, Michael Goris, MD, Robert DeBusk, MD, FACC, Stanford University Medical School, Stanford, Ca.

To evaluate the effects of 10 days' bedrest (BR) on the ventricular response to exercise, 10 healthy men 50±4 years underwent equilibrium gated blood pool scanning during multistage supine and upright bicycle ergometry performed immediately pre and post BR. During all supine and upright exercise, subjects completed at least 3 minutes of a workload equivalent to 75% of their predetermined maximal workload of 1108±49 kgm/minute. RESULTS: Following bedrest, total body weight declined by 1.5 kg ($p<0.05$); resting supine left ventricular (LV) end-diastolic volume by echogram declined 17% ($p<0.05$); maximal oxygen consumption declined 6% during supine effort (NS) and by 15% during upright effort ($p<0.05$).

	SUPINE			UPRIGHT		
WORKLOAD	REST	25%MAX	75%MAX	REST	25%MAX	75%MAX
HR PreBR	71	99	143	80	108	154
PostBR	73	100	150	96†	126‡	166†
EF PreBR	60	66	72	68	74	76
PostBR	75‡	80‡	82†	75*	81*	83*

Pre vs post BR: *p< 0.05 †p< 0.01 ‡p< 0.001

CONCLUSION: In healthy middle-aged men following 10 days' bedrest: 1) the capacity for supine effort is maintained by an increase in ejection fraction which offsets a diminished left ventricular volume. 2) The capacity for upright effort declines despite an increase in ejection fraction and heart rate. 3) This indicates that orthostatic stress, not ventricular dysfunction, is the major cause of reduced exercise tolerance immediately following bedrest.

SIMILARITY OF THE HEMODYNAMIC RESPONSES TO STATIC AND DYNAMIC HANDGRIP

Steven F. Lewis, PhD; W. Fred Taylor, MS; Bruce C. Bastian, MD; C. Gunnar Blomqvist, MD, FACC, Southwestern Medical School, Dallas, Texas.

The salient hemodynamic effect of static exercise is a pressor response persisting even during combined β-adrenergic and vagal blockade. The response to dynamic exercise has been considered distinctly different with little change in mean blood pressure ($\overline{BP}$). A large increase in cardiac output (CO) is matched by a marked decrease in total peripheral resistance (TPR). However, these concepts are based on comparisons of small muscle static exercise (handgrip) vs large muscle dynamic exercise (treadmill). In the present study active muscle mass was equalized in 6 healthy men performing static handgrip and dynamic handgrip to fatigue (6 min) in the sitting position without drugs and after combined autonomic blockade (metoprolol + atropine). Mean differences Rest-exercise ± SE were:

Mode of Contraction	Condition	ΔHR (bpm)	ΔCO (l/min)	Δ$\overline{BP}$ (mmHg)	ΔTPR (units)
Static	Control	13±1	1.5±.7	28±1	1.6±1.2
	Blockade	0±1	.4±.3	21±6	2.2±1.4
Dynamic	Control	20±6	2.0±.2	34±4	.7±0.3
	Blockade	-2±1	1.4±.2	22±5	.8±1.0

The typical fall in TPR seen in treadmill exercise did not occur in dynamic handgrip. A significant ($p<0.05$) increase in $\overline{BP}$ occurred irrespective of mode of contraction and condition although autonomic blockade abolished Δheart rate (HR) and attenuated ΔCO. Conclusion: The mode of contraction is a minor determinant of the hemodynamic response during static and dynamic effort involving identical small muscle groups.

ECHOCARDIOGRAPHIC CHANGES DURING A 1 YEAR EXERCISE PROGRAM IN PREVIOUSLY SEDENTARY MIDDLE AGED MEN

Dennis M. Davidson,MD; Richard L.Popp,MD,FACC; William L. Haskell,PhD; Peter D. Wood,DSc; Steven Blair,PED; Ping Ho, MA; Elizabeth London,BA. Stanford University, Stanford,Ca.

To examine changes in cardiac dimensions and function during a 1 year exercise program, 81 sedentary men, aged 35-55, free of cardiac disease, were randomized into supervised exercise (n=48) and control (n=33) groups. M-mode echocardiograms were done at entry, 3 months, and 1 year. In 35 men (43%), all 3 echocardiograms were of sufficient quality for accurate analysis. Of the 35 men, 20 were in the exercise group, and ran 2-34 km weekly.

These variables had significant changes: LV internal dimensions at end diastole (LVd) and end systole (LVs), stroke volume(SV)(LVd^3-LVs^3), LA diameter, resting heart rate (HR) and estimated LV mass. P values were identical for absolute, percentage and (absolute ÷ BSA) changes.

	EXERCISE			CONTROL			p of Δ at	
	Entry	3mos	Year	Entry	3mos	Year	3mos	Year
LVd	5.07	5.15	5.28	5.09	5.08	4.96	>.1	.001
LVs	3.14	3.22	3.23	3.21	3.13	3.09	.08	.03
LA	3.82	3.98	4.01	3.82	3.74	3.69	.06	.01
SV	99	103	114	101	101	93	>.1	.01
HR	66.4	60.9	56.5	68.9	67.2	70.7	.01	.0001
Mass	201	206	226	205	199	197	>.1	.01

There were no significant changes in percent fractional shortening, thickness or thickening of septum and posterior LV wall, or estimated cardiac output.

Conclusions: Compared to controls, middle-aged men undergoing yearlong exercise training had progressive increases in LV and LA chamber size, LV mass and stroke volume, decreased resting heart rate, and no change in fractional shortening, septum and posterior LV wall thickness or thickening, and estimated cardiac output.

EXERCISE INDUCED ARTERIAL HYPOTENSION - A NORMAL RESPONSE TO SEVERE EXERCISE

Allen F. Bowyer, MD; Lynn H. Orr, Jr., MD; Barbara L. Gilmore, East Carolina University School of Medicine, Greenville, NC.

Exercise induced hypotension (EXH) has been reported to be a sensitive indicator of coronary stenosis. This hypothesis was tested in 58 patients with angiographically documented significant coronary disease and 168 normal volunteers (age range 15-83) undergoing progressive, symptom limited treadmill or bicycle ergometer stress test. Both exercise methods began at approximately 3 METS and progressed by steps of 1-2 METS every 3 mins. to fatigue or symptom limit. Brachial artery pressure, 3 simultaneous lead ECG, heart rate, and symptoms were continuously recorded throughout exercise and 6 min. recovery.

Although the normal group was able to exercise to higher oxygen consumption, 73% of subjects in both groups demonstrated a drop of systolic blood pressure at or near their exercise limit. During fatigue limit exercise in normal subjects, 85% (80/94) between the ages of 20 and 40 demonstrated a significant drop of systolic and mean arterial pressure. This proportion was 69% (20/29), 64% (16/23), 37% (6/16), and 25% (1/4) for normal subjects aged 50, 60, 70, and 80, respectively.

EXH was found to be neither sensitive nor specific for coronary artery disease but appeared to represent a response shown by most subjects to the severe reduction of diastolic filling period at rapid heart rate.

E-DEPENDENT ENHANCEMENT OF VASCULAR PHOSPHOLIPID (PL) ACYLATION-REACYLATION CYCLE IN SPONTANEOUSLY HYPER- NSIVE RATS (SHRs).
therine Limas,MD and Constantinos J.Limas,MD;Veterans ministration Medical Center and the University of nnesota, Minneapolis, Minnesota.

bstrate availability is a key step in prostaglandin (PG) nthesis regulation and depends,to a large extent,on the tivity of membrane phospholipase A_2(PLase). We have com- red PG synthesis and Plase activity in aortas of SHRs d WKYs as a function of age.At 7 weeks,there is no dif- rence in either PG or Plase between the two groups.With lvancing age,aortic PG synthesis increases in both SHRs d WKYs but is significantly higher in hypertensive rats).52±0.04 nmol PGI_2/mg/15 min in SHRs at 42 wks compared 0.29±0.04 nmol/mg/15 min in WKYs,p<0.01). Plase activ- s remains unchanged in WKYs between 7 and 42 weeks, but SHRs,increases from 29±3 pmol/mg/hr to 88±6 pmol/mg/hr ring the same timer period. Maintenance of membrane in- grity in the face of increased PLase requires efficient plenishment of fatty acids into PLs. We,therefore,com- red the incorporation of ^{14}C-arachidonate(^{14}C-ara)into scular lipids of SHRs and WKYs. ^{14}C-ara esterification to PL was higher in SHRs(0.56±0.1 nmol/mg/hr vs. 0.32± 04 in WKYs,p<0.01)while labeling of neutral lipids was milar in the two groups. The pathways for removal of solecithin generated by the enhanced PLase activity were lso investigated. Lysolecithin-lysolecithin acyl trans- rase and lysolecithin acyl-CoA transferase activities d not differ in the two groups. Lysolecithinase activity, owever,was significantly higher in SHRs(751±35 pmol/mg vs 03±22 in WKYs,p<0.01).These results indicate that vascu- r PL deacylation-reacylation cycle is enhanced in SHRs cause of increased formation and removal of lysolecithin. is enhancement parallels the increase in PG synthesis d may determine substrate delivery to the synthetase.

N EXPERIMENTAL MODEL TO DEMONSTRATE OBJECTIVELY THE AS- OCIATION OF LABILE HYPERTENSION TO VASCULAR COMPLICATION
bid A. Shah, M.D.; Robert Barndt, M.D., University of outhern California, Los Angeles, CA.

he association between labile hypertension and vascular omplications has been suspected epidemiologically. In he absence of an objective method of validation, we de- igned a prospective, randomized study to investigate his quantitatively. Twenty-four New Zealand rabbits ere randomized into three equal groups. One group of 8 abbits were used as age-matched controls. Two other roups were fed a high (2%) cholesterol (Chol.) diet for months. One group of Chol. fed rabbits was given ran- om numbers of norepinephrine (NOR) infusions (1 mg per 0 minutes) daily during the fourth month of Chol. feed- ng to induce labile hypertension. Significant elevation f blood pressure (BP) compared to baseline BP was obta- ned (mean=172, range=140-190mm Hg, P<0.001). The dura- ion of NOR effect on vascular tone was assessed by serial ngiography before and after NOR infusion. Both BP and uminal diameter changed significantly during infusion, ut both returned to normal within 30 minutes, demonstra- ing the transitory effect of NOR. Risk factor levels id not differ significantly between the high Chol. and he NOR group (mean values: Serum Chol.=1800 mg%, serum riglyceride=252mg%, and systolic BP= 110mm Hg.). At au- opsy, the extent of atherosclerosis was significantly reater (P<0.025) in the NOR group (mean=76%, range 62-94), compared to the high Chol. group (mean=53%, range 25- 0%), and was reproducible (R=0.99, SEE=3%). Linear re- ression analysis revealed a significant correlation be- ween the number of NOR infusions and the atherosclerotic rea (R=0.59, P<0.005).
n conclusion, brief periods of significant BP elevations an produce accelerated atherosclerosis compared to con- rols with identical risk factors.

EFFECT OF DIETARY SODIUM AND POTASSIUM CONTENT ON SYMPATHETIC ACTIVITY IN spSHR.
Albert Schömig, MD, Rainer Dietz, MD, Wolfgang, Rascher,MD Ruth Strasser, MD, and Wolfgang Kübler, MD, Dept. of Cardiology University of Heidelberg, Germany.

Dietary sodium loading in stroke prone spontaneously hyper tensive rats (spSHR) accelerates the rise in blood pres- sure whereas a potassium rich diet causes an attenuation of the development of hypertension. Since sympathetic ac- tivity and vascular reactivity to noradrenaline (NA) is elevated in spSHR as compared to WKR, we investigated the effects of changes in dietary sodium and potassium content on these parameters. The reactivity of vascular smooth muscle to NA was enhanced following dietary sodium loading as compared to normal fed animals and rats on a diet in which sodium was partially replaced by potassium (HSP diet : 650 mmol NaCl/kg and 200 mmol KCl/kg). A high sodium diet (HS diet: 1000 mmol NaCl/kg) for a period of 14 days resulted in a rise of plasma NA concentration after cold exposition from 368 ± 53 to 842 ± 30 ng/l and of adrenali- ne (A) from 245 ± 72 to 1168 ± 357 ng/l, being markedly less pronounced in normal fed spSHR NA from 244 ± 30 to 448 ± 51 ng/ml and A from 202 ± 56 to 374 ± 49 ng/l. In addition, a supersensitivity of vasculature to NA was ob- served (ED_{50}: 1.66 ± 0.18 vs 2.4 ± 0.26 µmol NA), which was the consequence of a reduced cocaine dependent uptake (uptake 1) of NA after a high sodium diet (70 ± 3 vs 96 ± 8 pmol/min/g tissue). Feeding with the potassium substitu- ted diet (HSP) improved the diminished uptake capacity by 50% in comparison to the high sodium group. In conclusion, a high dietary content of sodium further enhances sympa- thetic activity and vascular reactivity in spSHR. This can be ascribed, in part, to a reduction of neuronal uptake of NA, wich is restored to normal by partial replacement of sodium by potassium in the diet.

ECHOCARDIOGRAPHIC EVIDENCE FOR EARLY LEFT VENTRICULAR HYPERTROPHY IN RENAL HYPERTENSIVE DOGS
Shigefumi Morioka, MD; Geza Simon, MD, Department of Medicine, University of Minnesota and V.A. Medical Center Minneapolis, MN.

To investigate the rate of development of LV hypertrophy, LV wall thickness was measured with M-mode echocardio- graphy in 10 awake male dogs for several weeks before (control) and for 6 weeks after the induction of hyper- tension. Hypertension was produced by wrapping (Wx) one kidney in silk followed 2 weeks later by contralateral nephrectomy (Nx). Echocardiographic measurements were performed 2 to 3 times weekly and were averaged. Three dogs with sham-Wx and contralateral Nx served as con- trols. Results (mean±SE) in hypertensive dogs were:

Weeks	Control	Wx 1	Wx 2	Nx 1	Nx 2	Nx3-4	Nx5-6
MAP	125	138	141*	173***	185***	185***	184**
(mmHg)	± 3	± 7	± 4	± 5	± 9	± 13	± 15
WTd	8.0	8.2	8.8***	9.5***	9.9***	10.4***	10.8***
(mm)	±0.2	±0.2	± 0.3	± 0.3	± 0.4	± 0.3	± 0.4
Dd	44	44	44	44	44	43**	43*
(mm)	±1.4	±1.3	± 1.5	± 1.6	±1.2	±1.3	±1.6

MAP is mean arterial pressure; Dd and WTd are enddiastolic LV dimension and LV wall thickness; *p<0.05, **p<0.01, ***p<0.001 (paired t test). Heart rate did not change during the study. There were no echocardiographic changes in control dogs. The change in WTd between the control period and 2 weeks after wrapping was unrelated to the change in MAP during the same time (r=0.13, N=10). LV hypertrophy is detectable by serial echocardiograms early in hypertension with minimal increases in MAP, suggesting that humoral or neurogenic factors also may contribute to its development.

PEDIATRIC ECHOCARDIOGRAPHY
4:00-5:00

TWO-DIMENSIONAL (2D) ECHOCARDIOGRAPHIC IMAGING OF ATRIO-VENTRICULAR (AV) VALVES, SEPTAL STRUCTURES, AND RUDIMENTARY OUTFLOW CHAMBERS (RC) IN PATIENTS WITH UNIVENTRICULAR HEARTS (UH)

David J. Sahn, MD, FACC; Joyce R. Harder, MD; Robert M. Feedom, MD, FACC; Walter J. Duncan, MD; Richard D. Rowe, MD, University of Arizona, Tucson and University of Toronto, Canada.

In this study we used electronically or dynamically focussed high resolution 2D echo systems to image 44 patients, angiographically, surgically or autopsy proven to have UH. Thirty-three had UH of LV type. Five patients had UH of RV type. Two of these had blind trabecular pouches and no outflow from the RC. Six patients had indeterminate UH without RC. The diagnosis of UH was correctly achieved using 2D echo in all but 2 of the earliest (1974) patients. 2D echo also correctly predicted 25 of 27 with double inlet main chamber (MC), 5 patients with absent left and 12 with absent right AV connection. AV valve overriding the RC (surgically confirmed) was also correctly identified in 2. Thirty-four of 36 RC's giving rise to a great artery were identified by echo with imaging of trabecular septum, conus or outlet septum and the outlet foramen (OF). One of 2 small blind trabecular pouches was missed on echo. The other was missed on angio but was present at autopsy. UH of LV type could be predicted by an RC not coming to the crux of the heart, coarser trabeculation in the RC than in the MC and imaging of the posterior medial muscle bundle on the posterior wall of the MC. UH of RV type could be identified by the more inferior positioning of the OF, an RC coming down to the crux of the heart near the AV groove and RC with a more posterior position. RC could be identified whether left or right sided especially when using apex 4 chamber or subcostal views. 2D echo provides detailed analysis of AV valve morphology, MC morphology and RC size and position in patients with UH.

ECHOCARDIOGRAPHIC DIAGNOSIS OF ABSENT PULMONARY VALVE SYNDROME IN THE NEONATE

John P. Cheatham, MD, Larry A. Latson, MD, Howard P. Gutgesell, MD, FACC. The Lillie Frank Abercrombie Section of Cardiology, Department of Pediatrics, Baylor College of Medicine and Texas Children's Hospital, Houston.

Infants with absent pulmonary valve syndrome (APVS) frequently present in the neonatal period with cyanosis, heart murmur, and respiratory distress. To determine if there were unique echocardiographic features of APVS, we performed echocardiograms on 7 infants with this condition (confirmed by cardiac catheterization). The mean age was 11.8 days. By M-mode echocardiographic measurement, the right ventricle was dilated (mean, 14.3 mm) and hypertrophied. In 6 subjects the aorta was enlarged and straddled the septum. In all 7 neonates a single semilunar valve was detected. The septal motion was abnormal in 6: paradoxical in 5, markedly reduced excursion in 1. In the subject without pulmonary insufficiency clinically, septal motion was only slightly reduced. Two-dimensional echocardiograms (2-D Echo) in 3 infants demonstrated subaortic ventricular septal defect, narrowing of pulmonary annulus, and dilatation of the main pulmonary artery.

The unique features of abnormal septal motion in combination with a single overriding great artery are highly suggestive of absent pulmonary valve syndrome, and help distinguish this condition from tetralogy of Fallot or truncus arteriosus by M-mode echocardiography. Demonstration of a narrow pulmonary annulus and dilated main pulmonary artery by 2-D Echo help confirm the diagnosis.

EVALUATION OF TRICUSPID ATRESIA BY TWO-DIMENSIONAL ECHOCARDIOGRAPHY

José Colό, MD; A. Rebecca Snider, MD, FACC; Norman H. Silverman, MD, FACC, University of California, San Francisco, Ca.

We reviewed the two-dimensional echocardiograms (2DE) of 13 patients (pts) aged 6 hrs. to 25 yrs. with tricuspid atresia (TA) to determine the anatomic type according to Edwards & Burchell and to evaluate the size of the right ventricle. From the parasternal short axis view, we measured the diameters of the Ao and main PA with a computerized light pen in order to estimate the PA size and pulmonary blood flow. The 2DE findings were compared to the findings at cardiac catheterization and cinéangiography. From the 2DE, the anatomic type of TA was predicted correctly in 10 pts and incorrectly in 2 pts. In one pt, the echocardiogram was technically inadequate for anatomic classification. In 11 of the 13 pts, the right ventricular size estimated from the 2DE was identical to the right ventricular size estimated from angiography. The ratio of the diameters of the Ao and PA (Ao/PA) measured from the 2DE (Ao/PA 2DE) was comparable to the ratio of the diameters of the Ao and PA measured from the angiogram (Ao/PA angio)($r = 0.91$, SEE $= \pm 0.21$). The PA diameter measured from the 2DE and corrected for body surface area (PA/BSA 2D) correlated well with the ratio of the pulmonary and systemic blood flows (Qp/Qs) determined at catheterization ($r=0.80$, SEE $= \pm 0.56$). The 2DE was an accurate indicator of the anatomic type of TA as well as the size of the right ventricle, pulmonary artery, and pulmonary blood flow. 2DE provides a safe, non-invasive technique for the serial evaluation of patients with TA both before and after surgical intervention.

TWO DIMENSIONAL ECHOCARDIOGRAPHIC ESTIMATION OF LEFT VENTRICULAR VOLUME IN SMALL NEWBORN LAMB HEARTS.

Barry Baylen, MD, FACC; Yoshiro Yoshida, MD; Ismael Mena, MD; George Emmanouilides, MD, FACC, Harbor-UCLA Medical Center, Torrance, CA

Two dimensional echocardiographic (2DE) estimations of left ventricular volume (LVvol) correlate well with angiographic volumes in older infants and children. However, such correlative studies are obviously difficult to obtain in newborn and preterm infants.

Hence, we evaluated 2DE for LVvol estimation in preterm and term postmortem lamb hearts (130 day gest-term-3wk). The volume of 22 fixed LVs were measured directly (range 0.8-9.9cc). The LVs were imaged in short and "long" axis views (rt. ant. oblique equivalent) in a saline filled chamber using a Toshiba phased-array ultrasonoscope. Forty-four 2DE images were digitized using an Informatek Simis 3 computer and LVvols were calculated using the following standard methods: (1)single plane area-length (A-L), and (2)Simpson's reconstruction. Directly measured LVvols(Y) were compared with 2DE calculated LV vol(X) using linear regression analyses.

		*r=	p=
A-L	$Y(Vol) = 0.79X_{echo}+.52$	0.96	<0.001
Simpson	$Y(Vol) = 0.85X_{echo}+.50$	0.95	<0.001

Excellent correlations* were obtained between measured and 2DE calculated left ventricular volumes.

The data suggest that (1)accepted geometric methods predict left ventricular volumes for even small preterm hearts, and (2)two dimensional echocardiography should ultimately provide good estimates of left ventricular volumes in the human newborn infant.

4:00-5:00

CARDIAC RHYTHM, ARTERIAL PRESSURE, AND URINARY CATECHOLAMINES IN HYPERTENSION WITH AND WITHOUT LEFT VENTRICULAR HYPERTROPHY.

Franz H. Messerli, MD, FACC; Louis B. Glade, MD; David G. Elizardi, MD; Gerald R. Dreslinski, MD; Francis G. Dunn, MD; Edward D. Frohlich, MD, FACC. Ochsner Medical Institutions, New Orleans.

Continuous ambulatory EKG and arterial pressure (Delmar Avionics) were recorded for 24 hr in 20 normotensive subjects (NTS), 11 patients with borderline hypertension (BHT), 15 with uncomplicated (normal EKG) essential hypertension (EHT), and 6 with left ventricular hypertrophy (LVH) on EKG, all untreated. Urinary concentrations of epinephrine, norepinephrine, and dopamine were simultaneously measured over 4 successive 4-hr periods and one 8-hr period. Results were as follows (mean ±1SEM).

	Arterial pressure	APC's	VPC's	Heart Rate
NTS	110±2.5/79±1.4	7.4±4.8	5.0±2.9	77±3
BHT	127±2.3/90±2.2	4.2±4.0	6.4±4.1	78±2
EHT	145±4.4/102±2.8	5.7±4.4	8.6±5.8	75±4
LVH	155±6.8/104±3.5	4.8±4.0	517±290*	80±5

*p<0.01 vs ETH

Epinephrine, norepinephrine, and dopamine excretion were comparable between the four groups and showed a significant (p<0.02) nocturnal fall. However, urinary catecholamines did not correlate with prevalence of APC's or VPC's, absolute values or variability of heart rate and arterial pressure. It is concluded that hypertensive patients with EKG evidence of LVH have a higher prevalence of VPC's (but not APC's) and thus are at a higher risk of ventricular arrhythmias and sudden death than patients with a similar arterial pressure without LVH. Urinary catecholamines are not causally related to prevalence of ectopic beats, diurnal fluctuation or variability in heart rate or arterial pressure.

EFFICACY OF 24 HOUR AMBULATORY ECG MONITORING AS A PREDICTOR OF SUDDEN DEATH IN HYPERTROPHIC CARDIOMYOPATHY

Barry J. Maron, MD, FACC, Daniel D. Savage, MD, Stephen E. Epstein, MD, FACC, NHLBI, Bethesda, Md.

Sudden death is a not rare sequelle of the natural history of pts with hypertrophic cardiomyopathy. However, the mechanism of these catastrophic occurrences is unknown. Our previous 24 hr ambulatory ECG monitoring studies showed in 99 pts with hypertrophic cardiomyopathy (who were not taking cardioactive medications), a particularly high prevalence (i.e., 66%) of high-grade (Lown, grade 3 or higher) ventricular arrhythmias, and specifically ventricular tachycardia (VT) (i.e.19%). Since the significance of these arrhythmias in identifying pts at high- risk for sudden death is not known, clinical outcome was followed prospectively for 3 yrs in these pts. Of the 84 pts who did not undergo ventricular septal myotomy-myectomy, 6 died suddenly, 1 died of chronic heart failure and 77 survived. Prevalence of sudden death during the follow-up period was the same in pts with high-grade arrhythmias other than VT (1 of 37 or 3%) and in pts with no or low-grade arrhythmias (1 of 29, or 3%). However, occurrence of sudden death was significantly more common in pts with VT on their 24-hr ECG (4 of 17 or 24%) than in pts without VT (2 of 66 or 3%; p< 0.02). We conclude: 1) high-grade ventricular arrhythmias are common on continuous 24-hr ECG in pts with hypertrophic cardiomyopathy and 2) while sudden death is relatively uncommon in patients with high-grade ventricular arrhythmias other than VT, the finding of VT on 24-hr ECG identifies a subgroup of patients at high-risk for sudden death; 3) 24 hr ECG monitoring should be performed in pts with hypertrophic cardiomyopathy and antiarrhythmic therapy begun if VT is identified.

PROLONGED QT INTERVAL AND AUTONOMIC IMBALANCE: A CLUE FOR THE PREVENTION OF SUDDEN DEATH IN MITRAL VALVE PROLAPSE

Paolo E. Puddu, MD; Julio F. Tubau, MD; Ryszard Król, MD; Jacques de Champlain, MD, PhD; André Pasternac, MD, FACC, Montreal Heart Institute and University of Montreal, Montreal, Quebec

Sudden death (SD) has been reported in pts with mitral valve prolapse (MVP) but the underlying mechanism remains unclear so that prevention cannot be easily achieved. Since an autonomic imbalance may lead to a prolonged QT interval and thus increase the risk for SD, we compared the heart rate corrected QT (QTc) and the levels of total plasma catecholamines (TPC) and norepinephrine (NE) in 15 symptomatic pts with documented MVP (mean age 48±3 years) and in 19 normal subjects (mean age 41±2 years). QT interval was calculated in lead II; TPC and NE were measured in the resting state, after an 8 hour fast, all medications being discontinued for at least four days. MVP pts were divided into 2 groups: A) QTc <440 ms; B) QTc ≥440 ms.

	NORMALS (N19)		A (N10)		B (N5)
QTc (ms)	398±4	* *	423±5	* *	453±5
TPC (pg/ml)	348±17	*	420±35	*	619±104
NE (pg/ml)	242±25	*	350±31	N S	376±52

$\bar{x}$ ± SEM; * p<0.05; ** p<0.005 (variance analysis)

Thus, MVP pts with prolonged QTc (≥440 ms) have the highest TPC and NE levels. This provides a rationale for adrenergic blockade in that subset of pts with prolonged QTc who may be at greater risk of sudden death.

DISTRIBUTION OF BODY SURFACE ECG POTENTIALS IN FAMILIAL QT INTERVAL PROLONGATION

J.A. Abildskov, M.D., F.A.C.C.; G. Michael Vincent, M.D., F.A.C.C.; A. Kerry Evans, Ph.D., Mary Jo Burgess, M.D., University of Utah, Salt Lake City, Utah

Body surface distributions of ECG potentials were determinded for 11 patients (age 5-37 years) with familial QT interval prolongation. Data were obtained with a 32 lead system that permits accurate prediction of total thoracic potentials (avg rms voltage error 35 μV). Leads were sampled simultaneously at 1 msec intervals and computer processed to yield serial isopotential maps and maps of ST-T and QRST deflection areas on a 12 x 16 matrix. Serial isopotential maps had more negative than normal anterior poles and vertical null lines. Quantitative analysis of ST-T and QRST area distributions showed characteristic features that help define pathophysiology of familial QT interval prolongation. Average ST-T and QRST area distributions were determined from 200 normal adult subjects and subtracted from those of prolonged QT interval patients. Resulting difference maps had prominent negative poles on the anterior or anterolateral thorax in 9 of the 11 cases. Peaks differed from the average normal by 1 to 4 standard deviations (SD) for the ST-T (avg 2.5) and 1 to 3 SD for the QRST (avg 2.1). It is unlikely findings were due to age differences of normal and test groups since 6 patients were above 25 years and none of the younger patients showed the juvenile pattern of inverted T waves in mid-precordial leads. Findings suggest prolonged repolarization in anterior and lateral ventricular walls which are normally innervated by right sided sympathetic fibers. Since denervation prolongs repolarization, findings are compatible with deficient right sympathetic effects which is one of the possible mechanisms of familial QT prolongation.

NUCLEAR CARDIOLOGY—DETECTION AND QUANTITATION OF MYOCARDIAL ISCHEMIA
4:00-5:00

β^+-PROBE DOCUMENTATION OF A DIRECT RELATION BETWEEN CLEARANCE OF ^{11}C-PALMITATE AND MYOCARDIAL METABOLISM
Rene A. Lerch, MD; H. Dieter Ambos; Steven R. Bergmann, PhD; Michel M. Ter-Pogossian, PhD; Burton E. Sobel, MD, FACC, Washington University, St. Louis, Missouri

To delineate the extent to which myocardial clearance of the positron emitter, ^{11}C-palmitate, depends on metabolism per se in open chest dogs, we developed a β^+ probe (10 mm diameter, 3.0 mm thick plastic scintillation crystal) to monitor β^+-radiation time-activity curves in selected subepicardial regions defined by the probe's dimensions and the short range of β^+ particles in tissue (4.0 mm for ^{11}C, 6.2 mm for ^{15}O). Annihilation gamma radiation contributed < 6% to observed count-rates, precluding contamination of results by tracer in the ventricular cavity or outlying myocardial regions. Nine dogs were subjected to intracoronary injection of 4 to 6 mCi of ^{11}C-palmitate and 1 mCi of $H_2{}^{15}O$ under conditions of controlled perfusion of the left anterior descending coronary artery via a femoral artery shunt. ^{11}C-palmitate clearance was monoexponential from 5 to 12 minutes after injection ($r = .99 \pm .003$ (SE)) with an average rate constant of $.076 \pm .012$ min^{-1} and with duplicate determinations agreeing within $6.3 \pm 2.0\%$. Duplicate myocardial blood flow determinations calculated from monoexponential clearance of $H_2{}^{15}O$ agreed within $3.6 \pm 0.7\%$. Perfusion with hypoxic blood at the same flow decreased clearance of ^{11}C-palmitate by > 70%. These results, based on detection of β^+ radiation in vivo rather than simply gamma radiation in isolated hearts demonstrate that externally detectable, decreased clearance of ^{11}C-palmitate is a direct consequence of impaired aerobic metabolism secondary to anoxia.

QUANTITATION OF MYOCARDIAL PERFUSION IN MAN USING OXYGEN-15 AND POSITRON TOMOGRAPHY.
Roger M.Allan, FRACP, Terry Jones, MSc, Christopher C.G. Rhodes, MSc, Jon D. Heather, Attilio Maseri, M.D. FACC and Andrew P.Selwyn, MRCP. MRC Cyclotron Unit and Royal Postgraduate Medical School, Hammersmith Hospital, London.

The non-invasive quantitation of regional myocardial perfusion (RMP) is an important goal in clinical cardiology. Steady state theory and inhalation techniques using $C^{15}O_2$ ($t_{½}$=123 sec) to label circulating H_2O have been used with positron tomography to measure cerebral blood flow. The difficulty in applying this methodology to the myocardium is the interference from radioactivity within the vascular compartment. To overcome this the vascular space was defined during the inhalation of $C^{15}O$. Using these principles, serial emission tomograms of the myocardium were performed in 8 anaesthetised dogs during continuous inhalation of $C^{15}O_2$. The vascular component of this signal was identified by tomography during inhalation of $C^{15}O$ and this data subtracted from the $H_2{}^{15}O$ data. The arterial blood concentrations of $H_2{}^{15}O$, required for calculations, were measured in a well-counter. A range of blood flows was studied using pharmacological interventions. Partial volume correction made using measurements from anatomical dissection correlated well with a new in-vivo approach using transmission scan data ($P<0.01$).

The results show images that clearly delineate the regional myocardial distribution of $H_2{}^{15}O$ with myocardial: lung ratio = 8.2 ± 0.9(SD). Calculated perfusion values ranged from 0.51 to 3.70 mls/gm/min. In similar studies in 5 patients resting values for RMP were calculated and ranged from 0.42 to 0.65 mls/gm/min. Myocardial oxygen consumption using $^{15}O_2$ was also studied.

These results suggest that RMP (ml/gm/min) may be measured non-invasively in man using positron tomography and inhalation of short-lived radioactive gases.

EVALUATION OF INFARCTED AND ISCHEMIC MYOCARDIUM WITH 18-FLUORODEOXYGLUCOSE, $^{13}NH_3$, AND POSITRON COMPUTED TOMOGRAPHY.
Robert C. Marshall, MD, Henrich R. Schelbert, MD, Michael E. Phelps, MD, Jan H. Tillisch, MD, Eberhard Henze, MD, Sung C. Huang, MD, UCLA School of Medicine, Los Angeles, CA.

To evaluate the possibility of non-invasively identifying both ischemic (Is) and infarcted myocardium, indices of basal myocardial perfusion (MP) and metabolic rate for glucose (MMRGlc) were analyzed in 7 patients (pts) 3-9 days post infarction and in 2 pts with angina decubitus using 18-fluorodexoyglucose (FDG), $^{13}NH_3$ (NH), and positron computed tomography (PCT). Experimental evidence suggests that Is MMRGlc does not decline linearly with blood flow and that an absolute increase in MMRGlc is observed in supply-demand imbalance if flow is maintained. Since the ratio of MMRGLC to MP should be greater in Is than nonIs and dead tissue, the degree of dispersion of the FDG/NH ratio, expressed as % variation about a medium value, was used to identify Is myocardium. Of 12 remote and acute infarcts, qualitative analysis of both FDG and NH images correctly localize 10. In 6 pts, 5 of whom had no clinical evidence of continued Is, the mean and maximal variability of FDG/NH were 12.5±3.8% and 29.7±8.5%, respectively. In 3 pts, all with additional clinical evidence of Is, the mean and maximal variability were 33.7± 17% and 116±52%. We conclude that these results encourage further investigation into the use of FDG, NH and PCT to identify both ischemic and infarcted myocardium.

POSITIVE LABELING OF ISCHEMIC MYOCARDIUM: A NEW APPROACH IN PATIENTS WITH CORONARY DISEASE.
Andrew P.Selwyn, MRCP, Roger M.Allan, FRACP, Victor Pike, PhD., Kim Fox, MRCP, Attilio Maseri, FACC. Hammersmith Hospital and MRC Cyclotron Unit, London, UK.

Positron labeling of natural substrates with quantitative tomography in-vivo provides a unique opportunity to label and study the anaerobic processes jeopardising ischemic myocardium. Carbon-11-acetate (^{11}C-Ac) has been produced for peripheral intravenous injection and 0.125 - 0.2 mCi/kg body weight was given to 8 healthy subjects (4 at rest and 4 during exercise). Serial emission tomograms showed a monoexponential decrease in the regional myocardial (RM) activity between 3 and 12 min. Washout in the 4 subjects at rest showed a $t_{½}=8.3 \pm 0.74$ min(SD), a rate constant = 0.084 ± 0.007 and a regional myocardial coefficient of variance (CV) of 8.7% (mean). The 4 subjects during exercise showed a $t_{½}=7.9 \pm 0.47$ min, a rate constant = 0.087 and a CV = 2.8%. 5 patients with angina and coronary disease were given 0.2 mCi/kg of ^{11}C-Ac 1 to 2 min before ischemic changes in the ECG during a standardised exercise test. Serial emission tomograms showed a homogeneous initial RM distribution of activity at 3 min. Thereafter the RM washout from the affected myocardium ($t_{½}$=10.1 min,(mean), rate constant, 0.069) was significantly different ($P=<0.01$) from the remote myocardium ($t_{½}$= 7.7 min,(mean), rate constant = 0.09). RM washout of activity was thus heterogeneous (CV=16%). The acutely ischemic myocardium was easily identified being positively labeled for up to 12 min after the normalisation of the ECG. The ratio of ischemic to remote myocardium at 12 min was 1.8:1. The data suggests that there are prolonged disturbances of ischemic myocardium beyond the ECG and symptomatic evidence. Natural substrates labeled with positron nuclides provide a new approach for the positive identification and investigation of acutely ischemic myocardium in patients.

PHARMACOLOGY: NEW ANTIARRHYTHMIC DRUGS AND CONCEPTS
8:30-10:00

SUCCESSFUL CONTROL OF THE CHRONIC FORM OF SUPRAVENTRICULAR TACHYCARDIA WITH ORAL VERAPAMIL HYDROCHLORIDE

Ruey J. Sung, MD, FACC; Candy Raphan, RN; Zulfikar Juma, MD, Arrhythmia Control Clinic, Department of Medicine, University of Miami, Miami, Florida.

Chronic supraventricular tachycardia (SVT), in contrast to the paroxysmal form of SVT, is characterized by its almost incessancy interposed by short periods of sinus rhythm. Verapamil hydrochloride (V) was used to treat 12 patients(pts) with the chronic form of SVT at rates ranging from 140 to 180 beats per minute. Three pts had sinus nodal reentrant tachycardia, 4 pts atrioventricular (A-V) nodal reentrant tachycardia and 5 pts A-V reciprocating tachycardia involving concealed retrograde conducting bypass tracts. All 12 pts were symptomatic and were resistant or intolerant to digitalis, propranolol, quinidine, procainamide and disopyramide used alone or in various combinations. V was given orally at dosages ranging from 320 to 800 mg per day and all pts were followed at bimonthly intervals at our arrhythmia control clinic. With a follow-up period of 5-23 (mean 14.6) months, all 12 pts had symptomatic improvement. Repeated holter monitoring during V therapy demonstrated that 8/12 pts manifested only atrial echo phenomenon and 4/12 pts slow, short-lived SVT at rates of less than 100 beats per minute. The therapeutic plasma V concentrations measured 112 to 572.6 (mean 232 ± 127) ng/ml. One pt developed headache, 1 pt constipation and 2 pts peripheral edema presumably due to venous relaxation effect of V. Each of these side effects was mild and clinically manageable. We conclude that oral V therapy is safe and effective for pts with the chronic form of SVT. In addition, this study suggests that V therapy may be tried before contemplating pacemaker therapy or surgical intervention in these pts.

ROLE OF SERUM T4 AND REVERSED T3 IN MONITORING ANTIARRHYTHMIC EFFICACY AND TOXICITY OF AMIODARONE IN RESISTANT ARRHYTHMIAS

Koonlawee Nademanee, MD; S. Melmed, MD; JoAnn Hendrickson, BS; A.W. Reed, MS; Jerome M. Hershman, MD; Bramah N. Singh MD, FACC, Wadsworth VA Hospital, Los Angeles, California

Amiodarone (Am), a potent iodinated antiarrhythmic drug, increases serum T4 and reversed T3 (rT3) without producing clinical hyper or hypo-thyroidism. Thus, T4 and rT3 and QTc were measured serially in 15 euthyroid pts with resistant (to other agents) cardiac arrhythmias (7 ventricular, 8 atrial) before, during and after withdrawal of Am (600-1000 mg/day) therapy and correlated with drug toxicity and antiarrhythmic efficacy (AE), documented by serial 24 hr Holter analysis. Results (mean±S.D.; *p<0.001):

	T4 µg/dl	rT3 ng/dl	Q-Tc
Predrug	7.8±2.2	37±7	0.44±0.03
3 week	12.1±2.8	67±22	0.48±0.02
Peak (2-5 wk)	15.9±3.2*	84±21*	0.49±0.04*
6 wk after drug stopped	9.5±1.9	55±5.5	0.46±0.04

Amiodarone increased T4 and rT3 in all patients; a linear correlation was found between an increase in rT3, AE and Q-Tc. AE was invariably associated with rT3 level >55 ng/dl and drug side effects with >100 ng/dl. The correlation with T4 was less striking. On drug withdrawal, side effects disappeared when rT3 fell <100 ng/dl and arrhythmias returned at levels <55 ng/dl.
Conclusions: 1) Serum rT3 provides a sensitive index to monitor efficacy (55-100 ng/dl) and toxicity (>100 ng/dl) of Amiodarone and 2) the data provides evidence for the drug producing a selective inhibition of T3 action on the heart as a potential basis for its antiarrhythmic effect.

ORAL FLECAINIDE ACETATE FOR ELIMINATION OF VENTRICULAR ARRHYTHMIAS IN MAN

Jeffrey L. Anderson, MD, FACC; James R. Stewart, MD; Benjamin A. Perry, MD; Daniel D. Van Hamersveld, MD; Theresa A. Johnson, RN; Bertram Pitt, MD, FACC, University of Michigan, Ann Arbor, Michigan

In order to determine the antiarrhythmic efficacy and safety of oral flecainide acetate (FA) in man, a placebo controlled dose-ranging and short-term oral maintenance study was undertaken in 13 patients (pts) with chronic, ventricular ectopy (VE) of frequency >600 VE/12 hrs. During a 2 day placebo control period, 11/13 maintained stable VE frequency (mean 11,254/12 hr,range 653-35,551) and entered dose-ranging. Dosage was increased in increments at 3 day intervals from 100-300 mg/12 hr until 95% VE suppression, limiting side effects, or dosage maximum was attained. Ten pts completed dose-ranging, and pt 11 experienced a transient ischemic attack and was excluded. Of the 10 pts, 9(90%) were complete responders (CR)(mean suppression 98.7%, range 96.1-100%), and one responded partially (68% suppression). Repetitive VE was totally eliminated in all 10 pts. Pt 11 showed 77% VE suppression on 100 mg/12 hr before exclusion. Of CR, 2 pts ended dose-ranging successfully at 100 mg, 5 at 200 mg, and 2 at 250mg/12 hr. Average dose calculated to achieve 95% suppression was 169 mg/12 hrs. A 3 day placebo-controlled drug washout period was accompanied by a significant return in VE in each of the 9 CR. VE first recurred at 21.9 hrs (range 7-40), and by 3 days VE averaged149.6% of control frequency. During the subsequent outpt trial, FA remained highly effective with total and average VE suppression of 98.0% and 94.6%, respectively. ECG response included prolongation ($p<0.01$) of PR(16.5%) and QRS (10.6%). Echocardiographic CI was unchanged. FA was well tolerated except for headache in 2 pts. Thus FA appears to be a highly effective antiarrhythmic in man.

FLECAINIDE ACETATE, A NEW ANTIARRHYTHMIC AGENT: DOSE-RANGING AND EFFICACY STUDY

Morrison Hodges, MD, FACC; J. Mark Haugland, MD; Gregory Granrud, MD; Richard W. Asinger, MD; Frank L. Mikell, MD; Jeananne Krejci, RN. Hennepin County Medical Center and the University of Minnesota, Minneapolis, MN.

Flecainide acetate (R-818) is a new antiarrhythmic agent with Class I properties. Potential advantages include a long plasma half-life (ave: 14 hr); effectiveness by both oral and IV routes; efficacy at relatively small doses; and few serious side effects noted to date. We evaluated flecainide with a single-blind dose-ranging and efficacy study in 9 patients with frequent ventricular ectopic depolarizations (VEDs). Patients were hospitalized and the ECG was monitored continuously by tape recordings which were analyzed quantitatively in a blinded fashion. Two days of placebo BID were followed by three increasing oral doses of flecainide (100, 200 and 300 mgm BID for 3 days each) until complete suppression or the 300 mgm BID dose was reached; 3 days of placebo BID were then observed to assure return of baseline rhythm and to evaluate plasma pharmacokinetics. During the 2-day control period, the patients averaged 15.2 VEDs/min (range 1.3-50.0), and all patients were observed to have complex ventricular arrhythmias (> Lown Class II). At the most effective dose (200 mgm BID in 6 pts, 300 mgm BID in 3 pts), average VED suppression was 96.0% (range 77.9%-100%), with 6 of the 9 achieving 100% suppression. During placebo washout, VED return averaged 146% of control. Outpatient treatment resulted in average suppressions of 99.6% and 99.5% at 1 and 2 wks, respectively. There were no significant changes in blood pressure or heart rate, but the PR, QRS and QTc intervals increased by 29%, 24% and 7% respectively ($p < .05$ for all). Observed side effects were an occasional sense of unsteadiness (4 pts), transient blurring of vision (1 pt), and a sense of warmth (1 pt). No side effect was serious enough to require discontinuation of drug. We conclude that oral flecainide, 200 or 300 mgm BID, is highly effective at suppressing VEDs and complex ventricular arrhythmias. Side effects in these 9 pts were minimal.

DOSE RELATED HAEMODYNAMIC EFFECTS OF INTRAVENOUS ENCAINIDE.

Jennie M.Metcalfe M.R.C.P.,Kieran M. Daly, M.R.C.P.I., Lynne Atkinson BSc,Mark Monaghan, David E.Jewitt F.R.C.P.
Department of Cardiology, King's College Hospital, London, U.K.

The acute haemodynamic and metabolic effects of intravenous Encainide (E) in cumulative doses of 1.0 and 2.0 mg/Kg infused over 15 minute periods were measured in 14 patients with obstructive coronary artery disease. Baseline right and left heart pressures, left ventricular (LV) dp/dt and thermodilution cardiac output and coronary sinus blood flow, myocardial lactate and oxygen extraction were recorded. Measurements were repeated after completion of the 1.0 and 2.0 mg/Kg infusions of E and 30 minutes later.
On completion of the 1.0 and 2.0 mg/Kg cumulative infusions of E significant dose related falls occurred in cardiac index (2.7 to 2.3 to 2.2 L/min/m^2 $p< 0.02$), LVdp/dt max. (1595 to 1405 to 1276 mmHg/sec. $p< 0.01$) with a rise in peripheral resistance (21 to 25 to 26.5 Wood units $p< 0.02$) and coronary sinus blood flow (113 to 126 to 133 mls/min. $p< 0.005$). Coronary vascular resistance fell (0.90 to 0.79 to 0.76 units $p< 0.05$). The fall in LVdp/dt max. persisted for 30 minutes after E 2.0 mg/Kg (1595 to 1381 mmHg/sec. $p< 0.05$).
Minor and insignificant changes only occurred in heart rate, left ventricular end-diastolic pressure and myocardial lactate and oxygen extraction. Plasma E levels were in the therapeutic anti-arrhythmic range.
The dose related cardiac depressant effects observed with intravenous E indicate the need for caution when doses above 1.0 mg/Kg are used particularly in the presence of LV dysfunction.

ELECTROPHYSIOLOGIC EFFECTS OF PROPAFENONE ON CANINE ISCHEMIC CARDIAC CELLS

Robert H. Zeiler, MS; William B. Gough, PhD; Ruey Sung, MD, FACC; Nabil El-Sherif, MD, FACC, SUNY Downstate and VA Medical Centers, Brooklyn, N.Y.

Electrophysiologic effects of the new antiarrhythmic drug propafenone (P), (2-(3-propylamino)-2-(hydroxy)-propoxy-3-phyenylpropiophenone HCl) were studied by conventional microelectrode technique in two types of preparations from 24-hour-old myocardial infarction in dog: 1)epicardial strips containing myocardial cells (M) from ischemic and normal zones, 2) endocardial strips containing ischemic Purkinje fibers (PF). Of the concentrations tested, (0.1 mg/L - 25mg/L), the most effective dose range was 2-4mg/L. P resulted in a concentration-dependant increase in threshold of stimulation, slowing of conduction and reduction of amplitude, overshoot and V max of action potentials of M and PF but had no effect on resting membrane potential. These effects were more marked on depressed ischemic M and PF. We have recently shown that abnormal automaticity seen 24 hours following MI in dogs is due to triggered automaticity (TA), (Circulation, In press). In endocardial preparations from 24-hours-old MI, TA (rate 60-120/min) arising from delayed after depolarization (DAD) was consistently induced in depolarized ischemic PF by a critical cycle length during regular pacing or premature stimulation and only when DAD attained threshold. P depressed the amplitude of DAD, slowed and inhibited TA. We conclude: 1) P has a membrane anesthetic effect with depressed ischemic cells being more sensitive, 2) P also depresses ionic currents responsible for TA in depolarized PF. 3) Actions of P could result in an antiarrhythmic effect in vivo on both reentrant activation and abnormal automaticity.

NUCLEAR CARDIOLOGY—CLINICAL APPLICATION OF THALLIUM 201 MYOCARDIAL IMAGING
8:30-10:00

THE ADVERSE PROGNOSTIC SIGNIFICANCE OF AN ABNORMAL THALLIUM MYOCARDIAL PERFUSION SCINTIGRAM.

James Joye, MD, FACC; Joan Bogre; Kirk Huang, MD; Garrett Lee, MD; Reginald Low, MD; Patricia Takeda, MD; Lawrence Laslett, MD; Ezra Amsterdam, MD, FACC; Dean Mason, MD, FACC; Anthony DeMaria, MD, FACC, University of California, Davis, California.

No data are available which describe the prognostic significance of abnormal exercise thallium myocardial scintigrams (Tl scans). We therefore analyzed the natural history of 192 patients (pts) (mean age 55.9 yrs) followed over a mean interval of 35.5 months in whom Tl scans were performed. Of the 192 pts, 12 suffered cardiac deaths and two had noncardiac deaths. All scans were interpreted with attention to the location, size and severity of any defect and the number of standard views in which it was seen. Left ventricular dilation (LV dil) was also noted if the chamber appeared larger than 1.5 x the thickness of the posterolateral wall. Scan abnormalities were scored as a product of the percent circumference and percent loss of activity involved in the defect and expressed as the sum of defects in all three standard views. Among 31 pts with LV dil there were eight deaths compared with four of 159 pts without LV dil ($p<0.001$). Death occurred an average of 20.7 months following scanning. Of the 88 pts with exercise scans having defect scores of 30 or more eight died while none of the 84 with scores less than 30 died ($p<0.01$). While only four pts had myocardial infarction (MI) following scanning, none of 55 pts with an exercise defect score of <10 died or had a MI compared to 12 such events among 116 who had scores >10 ($p<0.025$). This study demonstrates a significantly higher mortality among pts found to have LV dil or large perfusion defects as scored by exercise Tl scan while showing no serious cardiac events following exercise scans with no or small defects.

UTILITY OF SERIAL THALLIUM IMAGING FOLLOWING DIPYRIDAMOLE

Jeffrey Leppo, M.D., Charles A. Boucher, M.D., FACC, Robert D. Okada, M.D., FACC, H. William Strauss, M.D., FACC, Gerald M. Pohost, M.D., FACC.
Massachusetts General Hospital, Boston, MA

Dipyridamole provides an alternative approach to exercise for detection of coronary artery disease (CAD) using Thallium-201 (Tl). Therefore, the presence and significance of Tl redistribution after dipyridamole was studied in 50 patients having coronary angiography, 30 with CAD and 20 normals. After 0.56 ml/kg/4 min intravenous infusion of dipyridamole, Tl was given and images in 3 views were obtained initially and after 2-3 hrs. Segmental Tl activity (3/view) was scored by 3 independent observers from 0 (no activity) to 2 (normal) using 0.5 grade steps. Using previously defined criteria for initially abnormal segments, the sensitivity was 93% (28/30) and specificity was 85% (17/20). There were 117 (43%) abnormal segments in the 30 CAD patients and 4 (2%) in the 20 normals. These 121 abnormal segments were then divided into 3 groups based on the completeness of Tl redistribution and compared to segmental wall motion as assessed by contrast ventriculography. In 34 segments with a persistent defect (no redistribution), 79% were akinetic and 97% showed either akinesis or hypokinesis; while in 58 segments with complete redistribution, only 9% demonstrated akinesis ($p<.01$).

These data suggest that serial Tl imaging after dipyridamole can detect CAD and assess myocardial viability in a manner similar to exercise Tl imaging.

THALLIUM-201 REDISTRIBUTION SCINTIGRAPHY PREDICTS THE RESPONSE TO LEFT VENTRICULAR ASYNERGIC SEGMENTS TO NITROGLYCERIN ADMINISTRATION

Alan Rozanski, MD; Daniel Berman, MD, FACC; Ronald Levy, MD; Nancy Pantaleo, RN; Jamshid Maddahi, MD; James S. Forrester, MD, FACC; Alan Waxman, MD; and H.J.C. Swan, MD, FACC. Cedars-Sinai Medical Center, Los Angeles, Ca.

Since redistribution (RDST) Tl-201 scintigraphy may reflect the extent of viable myocardium, the pattern of Tl-RDST may provide a useful noninvasive means of identifying asynergic (asyn) LV segments (segs) with latent reversibility. To test this hypothesis, 17 consecutive pts with resting wall motion (WM) abnormalities undergoing stress-RDST Tl scintigraphy and resting multiple gated equilibrium scintigraphy (MGES) with Tc-99m RBC's also underwent MGES with nitroglycerin (NTG). MGES after NTG was begun following a sustained blood pressure fall of 10mm Hg or heart rate increase of 10 beats/minute. For both Tl and MGES, anterior and 45° left anterior oblique images were divided into 5 segs. WM was assessed by a 5 point system (3=normal (nl), -1=dyskinesis). Asynergic segs with post-NTG WM=3 or by $\geq$2 from control were considered improved. Tl-RDST images, obtained 4 hours post-stress, were consensually read by 3 observers unaware of the WM results.

Of 49 asyn segs, 22 improved after NTG and 27 did not. Tl-RDST correctly predicted the WM response in 39 of the 49 segs. Tl-RDST was nl in 21 of 22 segs improving with NTG and was abnormal in 18 of 27 segs which did not improve ($p<.001$). Of note, only 1 of 19 asyn segs with nl Tl-RDST improved with NTG.

Therefore, the segmental pattern of Tl-201 redistribution scintigraphy predicts the response of asynergic myocardial segments to nitroglycerin and may thus be useful in assessing the potential reversibility of resting left ventricular wall motion abnormalities.

RELATIONSHIP OF THALLIUM-201 PERFUSION IMAGES TO REGIONAL MYOCARDIAL BLOOD FLOW IN MAN

Allen B. Nichols, MD, FACC; David K. Blood, MD, FACC; Melvin B. Weiss, MD, FACC; Paul H. Chen, MD; Paul J. Cannon, MD, FACC. College of Physicians and Surgeons, Columbia University, New York, N.Y.

Regional myocardial blood flow (RMBF) was measured at coronary arteriography in 28 patients (pts) also undergoing Tl-201 exercise and redistribution scintigraphy. Identical multicrystal scintillation cameras were used for Tl-201 scintigraphy and for measuring RMBF by the Xenon-133 clearance method. Appropriately magnified Tl-201 images (LAO projection) were superimposed on RMBF patterns. In 10 pts with normal exercise and redistribution Tl-201 images, RMBF was homogeneous at rest and during rapid atrial pacing. RMBF in the left anterior descending region did not differ significantly from RMBF in the circumflex region, either at rest (60.2±12 vrs 59.7±12 ml/100 gm·min) or during rapid pacing (82.4±22 vrs 86.2±22). Global left ventricular (LV) flow, however, ranged widely from 35 to 77 ml/100 gm·min at rest and from 45 to 114 during pacing. In 5 pts with persistent defects on Tl-201 redistribution images, resting RMBF was reduced by 19% in the defect zones (46.4±8) compared to regions with normal Tl-201 uptake (57.0±6;$p<0.01$). In 13 pts with exercise-induced transient Tl-201 defects who were paced to angina, average RMBF during pacing was consistently lower in zones of Tl-201 defects (64.2±18) than in zones with normal Tl-201 uptake (82.4±20; $p<0.001$). The mean difference between the normal and ischemic zones was 22%. Thus, 1) Tl-201 images are normal over a wide range of global LV flows if RMBF is homogeneous; 2) Tl-201 perfusion defects coincide with regional differences of myocardial flow averaging 22%.

SERIAL RIGHT VENTRICULAR THALLIUM IMAGING FOLLOWING DIPYRIDAMOLE AND RELATIONSHIP TO RIGHT CORONARY ARTERY DISEASE

Kenneth A. Brown, MD; Charles A. Boucher, MD, FACC; Robert D. Okada, MD, FACC ; Jeffrey Leppo, MD, Gerald M. Pohost, MD, FACC, H.William Strauss, MD, FACC, Massachusetts General Hospital, Boston, MA.

The right ventricle (RV) is frequently well defined on thallium imaging following dipyridamole. The relationship of RV thallium distribution to right coronary artery anatomy and left ventricular (LV) inferior wall thallium distribution was examined in 67 patients following dipyridamole. The RV and inferior LV wall were read on 10 minute and 2-3 hour delayed views in left anterior oblique and anterior position, and were interpreted as normal, or showing persistent defect (PD) or transient defect (TD).

The RV image showed TD in 18 patients; 18/18 (100%) had $\geq$50% stenosis of proximal or mid right coronary artery (P/M RCA), although inferior wall was normal in 9/18. Twenty-nine patients had both normal RV and inferior wall images; 27/29 (93%) had no P/M RCA disease. When the RV showed PD, the inferior wall segment was predictive: 4/4 patients with inferior wall defect had P/M RCA disease, while 6/6 with normal inferior wall did not. However, when RV showed normal distribution, only 3/5 patients with inferior wall TD and 2/5 with inferior wall PD had P/M RCA disease.

The sensitivity/specificity was then examined. Of the 67 patients,30 had P/M RCA disease, 4 had disease of RCA limited to distal portion and 34 had normal RCA. For P/M RCA disease, the sensitivity of RV imaging (PD+TD) was 77% and was 60% for inferior wall defect (PD+TD)(P=NS). Combined RV plus inferior wall sensitivity was 93%, which was significantly higher than either alone ($P<.05$). For distal RCA disease, the sensitivity of both RV and inferior wall imaging was 1/4. The specificity of RV was 84%, of inferior wall 87%, of combined RV plus inferior wall 71%.

Thus, with serial thallium imaging following dipyridamole: 1) RV transient defect is highly specific for P/M RCA disease, 2) the combinaton of normal RV and inferior wall distribution is highly predictive for absence of P/M RCA disease, 3) inferior wall defects were predictive of P/M RCA disease only when RV showed PD, 4) for P/M RCA disease, the evaluation of both RV and inferior wall distribution defects adds significantly to the sensitivity of either RV or inferior wall defects alone.

PREDICTING THE EXTENT AND LOCATION OF CORONARY DISEASE TWO-WEEKS POST-MYOCARDIAL INFARCTION BY THALLIUM-201 SCINTIGRAPHY

Robert S. Gibson, MD; George J. Taylor, MD; Denny D. Watson, PhD; Richard C. Crampton, MD, FACC; George A. Beller, MD, FACC, University of Virginia, Charlottesville, Va.

The ability of quantitative thallium-201 (Tl) scintigraphy to predict the extent and location of coronary artery disease (CAD) prior to discharge after acute infarction (MI) was evaluated in 65 consecutive patients (pts). All pts underwent coronary angiography (CA) and serial Tl imaging either at rest (12 pts) or following submaximal exercise stress (53 pts; target heart rate 120). Two or 3 vessel CAD was designated if abnormal Tl uptake and/or washout patterns were seen in 2 or 3 vascular scan segments, respectively. Of 181 vessels analyzed in the 65 pts, 116 stenoses (STEN) $\geq$ 70% were found by CA. Ninety-four of these (81%) were predicted by scintigraphy. The specificity for identifying vessel STEN was 91%. Sensitivity for detecting and localizing STEN supplying an infarct zone was 95% as compared to 63% for STEN perfusing myocardium remote from the acute infarct ($p<0.002$). Perfusion abnormalities were more frequently seen in the distribution of vessels with severe ($\geq$90%) STEN than in those with moderate (70-90%) STEN (86% versus 56%, $p<0.02$). A greater proportion of LAD and RCA STEN (90%, 38/42 and 89%, 31/35, respectively) were detected by scintigraphy than Cx STEN (64%, 25/39)($p<0.006$). In 26/35 (74%) pts with 2 or 3 STEN by CA, scintigraphy predicted multivessel CAD.

Thus, 2 weeks after MI Tl scintigraphy is useful for predicting the extent and location of CAD, particularly STEN in the LAD and RCA. Low level stress or rest imaging is highly sensitive for detection of $\geq$ 90% STEN but less so for 70-89% STEN.

RESULTS OF CORONARY BYPASS AT LEAST 10 YEARS AFTER OPERATION IN 250 PATIENTS

Gerald M. Lawrie, MD, FACC; George C. Morris, Jr,MD,FACC; Abraham Silvers, PhD; Don W. Chapman, MD, FACC; Baylor College of Medicine, Houston, Tex.

The aim of this study was to determine the outcome of coronary bypass operation in 250 patients (pts) operated upon between 1968 and 1971 and followed in all cases for at least 10 years. There were 224 males (89.4%). Mean age at operation was 51.2 years. One vessel (V) disease was present in 23.3% (58) pts, two V in 44.4% (111) pts, three V in 26.5% (66) pts, and left main (> 50%) in 6.0% (15) pts. Good left ventricular (LV) function was present in 66% (165) pts and poor in the remainder. Operation was for angina pectoris in 96.3% (241) pts. Follow-up obtained for 96.4% (241/250) pts. Perioperative mortality was 6.8% (17 pts). Survival at 10 years was for one V, overall 77% (45 pts); good LV 80% (40 pts); poor LV 70% (5 pts); two V overall 69%, (76 pts); good LV 78% (48 pts); poor LV 58% (28 pts); three V overall, 51% (35 pts); good LV 56% (23 pts); poor LV, 50% (12 pts); left main overall, 60% (9 pts). Graft patency between 5 and 10 years (mean 8.4 years) was 77.4% (257/332). Of 165 survivors, 58% (96) were asymptomatic, 26% (43) improved, while 16% (26) felt unchanged or worse. Of patients under 65 at followup, 76% were employed fulltime and 19% were not working. Cox multivariate analysis showed factors most predictive of 10 year survival were age at operation, preoperative LV function and the number of vessels diseased preoperatively. The favorable 10 year results obtained in this early group suggests that long-term relief of symptoms and good late survival can be obtained with coronary bypass. The fact that late annual attrition rates have remained stable is particularly encouraging.

BYPASS GRAFT SURGERY FOR CORONARY ARTERY DISEASE: A 10-13 YEAR FOLLOW-UP STUDY OF 741 PATIENTS

William C. Sheldon, MD, FACC; Gustavo Rincon, MD, FACC; Floyd D. Loop, MD, FACC; William L. Proudfit, MD, Cleveland Clinic Foundation, Cleveland, OH

Seven hundred forty-one consecutive patients (pts.) had coronary artery vein graft surgery between May 1967 and December 1970, including 632 men and 109 women, median age 50 yrs. Single-vessel disease (lesions > 75% except for 21 pts.) was present in 414 pts. (55.9%), double-vessel disease in 195 (26.3%), triple-vessel disease in 69 (9.3%), and left main disease in 63 (8.5%). Twenty-two pts. died in the hospital (3%). All but 2 were followed 114-159 mos. after surgery. Ninety-seven required repeat cardiac operations 1-136 mos. after operation. One hundred thirty-two pts. died 2-135 mos. after hospital discharge (at least 37 of noncardiac causes). Five and 10-year survival for the entire series was 89.4% and 77.3%, respectively. For subsets with single-vessel involvement, 5 and 10-year survival rates were 91.5% and 81.3%, respectively; double-vessel involvement 87.8% and 75.9%. triple-vessel involvement 84.8% and 62.3%, and left main disease 85.5% and 72.9%. In the absence of a control series of matched or randomized medically treated pts., only the Proudfit series of angiographically documented surgical candidates (1963-1965) is available for comparative purposes: 5- and 10- year survival for the composite series of 388 surgical candidates was 70.1% and 47.9%, respectively. For subsets with single-vessel disease, 5 and 10-year survival was 88.3% and 68.4%, respectively, double-vessel disease 68.5% and 51.4%, triple-vessel disease 56.5% and 29.5%, and left main disease 55.6% and 25.7%. It is suggested that surgical treatment has a favorable benefit on long-term survival for all subsets of pts.

FACTORS INFLUENCING RESULTS DURING 12 YEARS OF CORONARY ARTERY BYPASS SURGERY IN 7,362 PATIENTS.

Jack C. Manley, MD., FACC; James F. King, MD; Jacob Assa, St. Luke's Hospital, Milwaukee, Wisconsin.

Using a computerized data registry system, analysis was made of factors influencing surgical results during two time periods; early (1968-71) and late (1972-79). Surgery was performed at one hospital by 4 senior surgeons with similar degree of experience and basic approach. Surgical mortality in the early time period in 1,085 patients ranged from 16 to 6% normal left ventricle (N-LV) 6.1%, abnormal LV (ABN-LV) 12.7%. Surgical mortality in the later time period in 6,277 patients ranged from 3 to 1.8%. (NLV-1.4% and ABN-LV 2.6%). During those observation times, median age increased (I) from 51 to 54 years, frequency of multivessel disease I 71 to 78%, severity of ABN-LV decreased 60.9% to 46.2%, average number of grafts per patient I 2.3 to 3.6, early graft patency (average 15 days) I 86.2 to 94.4%, late graft patency (60 months) I 78-86%. Number of mammary grafts I from 66 to 5,922 with average overall patency consistently over 94%; complication rates during later time period decreased in all catagories except neurologic deficit; perioperative infarction rates decreased 6.1 to 2.5%; 8 year actuarial survival in early time period was 70.1% (N-LV 81.0%,ABN-LV 62.3%) with annual attrition rates of 3.75, 2.37, 4.75% respectively. In later time periods 8 year survival increased to 89.1% (N-LV 91.2%,ABN-LV 88.2%) with annual attrition rate of 1.37, 1.1 and 1.47% respectively. Lower risk of surgery survival is attributed to greater technical experience, expertise and technology, more complete revascularization with greater graft patency, better patient selection and management. Most recent patient cohort (1978-80) demonstrates further improvement of surgical mortality, complication rates, graft patency and survival.

TEN YEAR EXPERIENCE WITH THE INTERNAL MAMMARY ARTERY AS A CORONARY BYPASS GRAFT

Jack C. Manley, MD, FACC; James F. King, MD; Jacob Assa; St. Luke's Hospital, Milwaukee, Wis.

The internal mammary artery (IMA) has not gained wide acceptance as a coronary bypass conduit, in part because of doubt regarding its ability to provide adequate perfusion and because of the extra effort involved in mobilizing the IMA from the chest wall. Because of our own increasing experience and reliance on the IMA bypass graft (BG), we reviewed the results at one hospital of 4 senior surgeons between 1970 and 1980. These surgeons who have similar experience and basic approach began to use the IMA in 1970-71 (66 IMA BG). Since that initial experience, 5,922 IMA BG have been placed in 6,277 patients. Surgical mortality, complication rate, postoperative exercise stress test, exercise hemodynamics at catheterization, relief of angina, and 8 year survival rates are comparable between patients with both vein G and IMA. In patients undergoing postoperative catheterization and angiography because of angina after surgery, vein G patency to anterior descending, diagonal and marginal branches was 73% (720 G) whereas IMA patency in the same patients to similar vessels was 94% (420 G). Angiography from 1-8 years (average 60 months) revealed a larger size of IMA, rare atherosclerosis and continued high patency rates (> 92%). Similar palliation and clinical results were observed in patients with single IMA and single saphenous vein revascularization. The findings support experimental studies that indicate adequate myocardial perfusion with IMA BG. In view of higher patency rates, this conduit is preferable alone or in combination with saphenous vein BG.

EFFECT OF MEDICAL AND SURGICAL THERAPY ON PROGNOSIS IN PATIENTS WITH ISOLATED LEFT ANTERIOR DESCENDING CORONARY ARTERY DISEASE

Ezra A. Amsterdam, MD, FACC; Todd M. Grehl, MD, FACC; Garrett Lee, MD; James A. Joye, MD, FACC; Reginald I. Low, MD; Asher Kimchi, MD; Esther Tow; Edward J. Hurley, MD, FACC; Anthony N. DeMaria, MD, FACC; Dean T. Mason, MD, FACC, University of California, Davis, California.

The effect of coronary artery bypass graft surgery on prognosis in patients (pts) with isolated disease of the left anterior descending coronary artery (LAD) has not been clarified. Therefore, follow-up data were analyzed in 74 pts with isolated stenosis ($\geq$ 70%) of the LAD treated medically (Med, 51 pts) and by coronary artery bypass graft surgery (Surg, 23 pts) during the past 9 yrs. Duration of follow-up was 31 mos in Med and 46 mos in Surg pts. There were no significant differences ($P > .05$) between Med and Surg pts, respectively, in age (53 vs 53 yrs), sex distribution (males 42/51, 82% vs 16/23, 70%) or left ventricular (LV) ejection fraction (0.64 vs 0.69; $>$ 0.40 in all 74 pts). Prevalence of prior myocardial infarction (MI) was higher ($P < .05$) in Med than Surg pts (32/51, 63% vs 9/23, 39%). Mortality during the period of observation in Med pts was 7.8% (4/5, 3.0%/yr): 1 death in 20 pts without prior MI (1.9%/yr) and 3 deaths in 32 pts with prior MI (3.6%/yr); there was no mortality (0/23) in Surg pts. New MI was comparable in Med and Surg pts: Med pts - 6 (4.6%/yr) and Surg pts - 3 (3.4%/yr). Mortality in pts with isolated disease of the left anterior descending coronary artery associated with adequate LV function and no prior MI is low with both Med and Surg therapy but is increased in Med pts with prior MI.

UNSTABLE ANGINA: EFFECT OF MEDICAL VERSUS SURGICAL THERAPY ON SURVIVAL AND MYOCARDIAL INFARCTION.

Herbert N. Hultgren, MD, FACC; Udipi Shettigar, MD, FACC; Craig Miller, MD, FACC. VA Medical Center, Palo Alto, California.

A prospective, non-randomized data bank study of the effect of medical versus surgical management of patients with unstable angina included all patients with unstable angina seen at one hospital over an 8 year period. Patients were entered into the study after an initial 5 day period of medical treatment. Entry characteristics were similar in 104 surgical patients and 124 medical patients. The mean follow-up period was 40 months. Operative mortality was 2% (2/104). The incidence of operative infarction was 13% (13/104). Twenty-seven medical patients had late surgery for progressive angina without operative mortality. Results are summarized below for 5 year survival by initial treatment (S_1%), by treatment received (S_2%) and by crossover where medical patients are dropped when surgery is performed (S_3%). Cardiac deaths only are considered. Operative infarcts (OMI%) and total infarcts (TMI%) are shown:

	No.	S_1%	S_2%	S_3%	OMI%	TMI%
Med.	124	.75*	73%**	76*	0%	17%
Surg.	104	.91	91%	91%	13%	22%

* p = <.025 ** p = <.01

Non-survivors compared to survivors had a higher incidence of: 1) Age >60 yrs; 2) Diastolic BP >89 mm; 3) ST-T changes; 4) Three vessel disease; 5) Elevated LV diastolic pressure (rest); 6) Elevated LV diastolic pressure (exercise). None had single vessel disease. Surgical therapy in this high risk study group improved survival but total infarcts were not reduced due to the incidence of operative infarction.

LONG TERM PROGNOSIS IN CARDIOVASCULAR DISEASE
8:30-10:00

CLINICAL IMPLICATIONS OF SERUM DIGOXIN CONCENTRATIONS

H.R. Ochs, MD; D.J. Greenblatt, MD; J.S. Harmatz; G. Bodem, MD; H.J. Dengler, MD, Med. Univ.-Klin., Bonn, W. Germany, and Tufts-New England Medical Center, Boston.

Factors influencing serum digoxin concentrations (SDC), and the relation of these levels to classical ECG and clinical manifestations of toxicity, were assessed in a series of 463 consecutively hospitalized patients of mean age 58 years. ECG variables were assessed by a blind observer who had no knowledge of SDC or patients' clinical status. Patients completed a standardized questionnaire assessing the presence or absence of subjective symptoms usually associated with digitalis toxicity; these were also scored by a blind observer. The majority of patients were receiving beta-acetyldigoxin (n=212) or beta-methyldigoxin (n=136). Age, sex, creatinine clearance, and weight-corrected dose collectively explained less than 7% of overall variability in SDC. Creatinine clearance, which declined significantly with age ($r=-.36$, $p<.001$), was the most important of these determinants. ST-segment depression was present in the majority of patients and became more common at higher SDC (Chi-square=22.6, $p<.01$). However, PR interval, QRS duration, QT interval, or the presence of AV block were not associated with SDC. Among 75 patients with atrial fibrillation, ventricular rate did not decline with increasing SDC, but was in fact positively correlated with SDC ($r=.20$). The presence of gastrointestinal, neuromuscular, or psychiatric symptoms classically attributed to digitalis toxicity was not significantly associated with SDC. SDC appear to be of limited value in assessing ECG and subjective manifestations usually associated with digitalis toxicity.

HIGH DENSITY LIPOPROTEIN AND TOTAL CHOLESTEROL AS PREDICTORS OF 7-YEAR MORTALITY FROM CORONARY HEART DISEASE, CANCER AND ALL CAUSES

Uri Goldbourt, MA; Shlomit Yaari, BA; Henry N. Neufeld, MD, FACC, Sheba Medical Center, Tel Hashomer, Israel.

10059 adult civil servants and municipal employees aged 40-65, were examined in the Israeli Ischemic Heart Disease Study. 475 (4.72%) died during a 7-year follow-up. For the 6562 last examinees, high density lipoprotein cholesterol (HDL) levels were determined. 305 of these died (4.65%). A J-shaped relationship which persisted after removing the early mortality (first two years) was observed between total cholesterol (CHOL) and total mortality (age adjusted mortality rates in the first through fifth CHOL quintiles: 44, 40, 39, 46, and 63 per 1000, respectively). An inverse relationship was observed between HDL and total mortality, the corresponding rates being: 63, 44, 39, 44 and 36 per 1000. In a multivariate logistic regression (MLR) the association with CHOL vanishes while that with HDL is augmented (adjusted relative odds, associated with decrease of one standard deviation = 1.21, $p < .005$). Coronary heart disease mortality is related dose response to both CHOL and (inversely) HDL, the latter relationship emerging the dominant one after adjustment for age and 8 other risk factors in MLR. No clear cut association of CHOL or HDL to cancer mortality is observed. Even in the absence of previously suggested toxicity of very low cholesterol, it would appear a more prudent preventive policy to pursue the elevation of HDL cholesterol rather than the reduction of low density lipoprotein cholesterol, particularly at the older age span.

FAMILIAL HYPERCHOLESTEROLEMIC FAMILIES' RESPONSE TO FOOD PRODUCTS CONTAINING LBG

James H. Zavoral, MD; Donna Fields, RD; Madge Hansen, RD; Kanta Kuba, MS; Ivan Frantz, MD; David Jacobs, PhD, University of Minnesota, Minneapolis, Minnesota

Familial hypercholesterolemia (FHC) is associated with severe premature coronary artery disease, death, and is resistant to dietary treatment. A special diet was developed to evaluate the lipid-lowering effect of Locust Bean Gum (LBG) in food products fed to adults and children from families with familial hypercholesterolemia as a potential aid in preventing coronary artery disease. Twenty-eight adults and children (20 FHC, 8 N) were divided into two groups, using a crossover design, and fed food products with and without LBG (8-30 gm/d) as outpatients in four-week periods. Diet records, food product consumption, lipids, and lipoproteins were analyzed every two weeks. Total cholesterol was lowered 11% ($\bar{m}$ 275 to $\bar{m}$ 246) in Group A at four weeks and 16% ($\bar{m}$ 255 to $\bar{m}$ 215) in Group B at six weeks ($p < .01$). The difference in cholesterol between the LBG and control diet was 19% at four weeks ($p < .01$). Low-density lipoprotein (LDL) fell 10% at four weeks in Group A and 20% at six weeks in Group B. High-density lipoprotein (HDL) did not change. HDL/LDL ratios increased. Lipid lowering was proportionate to starting levels in FHC and N in adults and children. LBG food acceptance was good. There were no significant side effects of the diet. LBG was more effective than some pharmacological agents in lowering serum lipids, and, in outpatients, appears to be one of the most effective dietary treatments of FHC. LBG in food products appears to be a safe, effective means of lowering serum lipids in normal and hyperlipidemic members of FHC families.

PROGNOSIS OF MEN AFTER FIRST ACUTE MYOCARDIAL INFARCTION IN THE 1960's AND 1970's: SEARCH FOR A SECULAR TREND

Eve Weinblatt, AB; William Ruberman, MD, FACC; Judith D. Goldberg, ScD; Charles W. Frank, MD, FACC; Mary Monk, PhD Health Insurance Plan of Greater New York, New York City

A decline in coronary heart disease (CHD) mortality in the U.S. of about 20% took place between the late 1960's and the end of the 1970's. The extent to which this decline may reflect changes in cardiovascular risk factors (primary prevention) and/or improved medical care for coronary patients (secondary prevention) is unknown. The existence of data from two CHD prognosis studies among men enrolled in HIP in the 60's and 70's provided a unique opportunity to examine a specific issue: over this 10-year period was there any suggestion of improved long-term prognosis among men who had survived a first acute myocardial infarction (MI)?

Cohorts for this comparison consisted of men aged 35-64 who met identical study criteria for a first definite MI, had a baseline examination, and were followed for mortality for periods up to 4½ years thereafter. The 60's study provided 436 men and the 70's study 697 men for the new analyses. The 70's cohort was examined sooner after MI and had greater proportions with ST depression, angina, and failure than the 60's cohort. Improved hospital care for the acute MI's in the 70's might have resulted in the survival to baseline of a greater proportion of men with more advanced heart disease. But the subsequent prognosis showed no advantage for the 70's cohort even after adjusting for the differences in clinical and personal characteristics of prognostic importance. We conclude that any contribution of improved medical care to the secular decline in CHD mortality is probably restricted to the acute stage of myocardial infarction.

PREDICTIVE VALUE OF THE MINNESOTA CODE CRITERIA FOR ACUTE MYOCARDIAL INFARCTION: CORRELATION WITH TECHNETIUM 99m PYROPHOSPHATE SCINTIGRAPHY AND SERUM ENZYME EVALUATION

Marian C. Limacher, M.D., William H. Fennell, M.D., James B. Young, M.D., FACC, Nicholas Kutka, M.D., James K. Alexander, M.D., FACC, Richard R. Miller, M.D., FACC, Baylor College of Medicine, Houston, Texas.

Although the Minnesota Code electrocardiographic (ECG) criteria for documenting acute myocardial infarction (AMI) is the epidemiologic standard for national multicenter trials, validation by current sensitive indices of myocardial necrosis is incomplete. We determined the sensitivity and predictive accuracy of Minnesota Code Class using technetium 99m pyrophosphate (TcP) scans and serum cardiac enzyme (SE) confirmation of AMI. Minnesota Code criteria: I = presence of .04 sec Q waves; IV = J point and ST depression; V = T inversion; IX = J point and ST elevation. TcP scans were regarded as positive when uptake was well defined and either diffuse or localized (i.e., ≥2+). Scans were performed within 3.5 days (mean) of admission and interpreted in a blind fashion. Daily ECG and/or SE were abnormal in 104 consecutive patients undergoing TcP to diagnose AMI. Positive (+) SE = two cardiac enzymes ≥ twice normal.

MC Class (No.)	+SE and +TcP (%)	-SE and -TcP (%)	+SE and -TcP (%)	-SE and +TcP (%)
I (22)	14 (64)	4 (18)	4 (18)	0
IV (20)	2 (10)	10 (50)	8 (40)	0
V (50)	2 (4)	30 (60)	17 (34)	1 (2)

The predictive values of Minnesota Code for diagnosing acute myocardial infarction (+SE and +TcP) were I=78%, IV=16%, V=6%, IX=30%. Thus, 1) the predictive value of MC Class I is satisfactory; however, its sensitivity is only 64%; 2) criteria for non-transmural MI, though sensitive, are very non-specific.

COHORT ANALYSIS OF SECULAR CHANGE IN MORTALITY IN PATIENTS WITH CAD UNDERGOING SURGICAL INTERVENTION

A.Oberman; G.Cutter; N.Kouchoukos; W.Rogers; R.Russell; H.Cohen. The University of Alabama in Birmingham, Birmingham, Alabama.

In this paper we examine mortality trends on patients undergoing bypass surgery over the past 10 years at the UAB and VA hospitals in Birmingham. Three year survival rates have risen from under 88% to over 92% for those undergoing surgery from the early '70s to the late '70s. Cohort life table analyses by degree of stenosis and year of surgery show that for persons with >75% stenosis the actuarial one year survival rate has risen from 80% before 1970 to 93.3% in '71-'72; and 95.1% for '77-'78. Two year survival rates rose from 91.3% in '71-'72 to 93.9% in '73-'74 to 94.3% in '75-'76. Changes in the age adjusted death rates in the U.S. for major cardiovascular diseases declined from 350 per 10,000 in 1969 to 340 in 1970 and 335, 334, 327, 311, 291, 284 for 1971-76 respectively. The gains in patients' survival appear to be greatest between the '71-'72 cohort versus the '73-'74 cohort. The lack of similar changes in the relative survival rates suggest real improvement in surgical management as opposed to simply secular trends in mortality. Similar changes and shifts between '71-'72 and '73-'74 were found for patients with 50-75% stenosis. These secular changes are not explained by differences in severity of disease, age, and sex in the patients undergoing surgical intervention.

THE VENTRICLES III: MAPPING
8:30-10:00

NON-COMPUTERIZED ON-LINE EPICARDIAL AND INTRAMURAL MAPPING OF VENTRICULAR ARRHYTHMIAS.
Eugene Downar, MD; Ian Parson, PhD; Paul Mendler, Dept. of Medicine, University of Toronto, Toronto, Canada;

In 6 in-situ canine hearts, local electrograms (LE) from 112 transmural multipolar needle electrodes were recorded on video tape by a multiplexing technique. The electrode positions were displayed in a polar projection of the heart on a video screen. Activation at each site was monitored continuously by differentiation of the dominant negative deflection of the LE and indicated by light intensification of the video display. Recording this data in video format enabled instant playback to be made one frame at a time. Each frame showed activation at 8 msec intervals. Ventricular pacing from the electrode sites demonstrated localization of the point of origin to within one centimeter. Subepicardial mapping was displayed by selecting a deeper electrode on all needles. Coronary occlusion produced a defect in the displayed image which was maximal at 7 mins but was markedly reduced by 15 mins. Ventricular ectopics and runs of ventricular tachycardia emerged from within the ischemic border. Reperfusion produced ventricular fibrillation by disintergration of the activation sequence within 1 or 2 cycles as well as by acceleration of monofocal tachycardias originating in the subendocardium. Multiplexing and video techniques offer an effective means of mapping myocardial activation.

CONFIRMATION OF A NEW TECHNIQUE FOR DETECTING SLOW VENTRICULAR ACTIVATION ON THE BODY SURFACE
Michael B. Simson, MD, FACC, David E. Euler, PhD, Eric L. Michelson, MD, FACC, Rita Falcone, BS, Joseph F. Spear, PhD, FACC, E. Neil Moore, DVM, PhD, FACC, University of Pennsylvania, Philadelphia, PA.

We tested the hypothesis that slow, fractionated ventricular activation after myocardial infarction (MI) can be detected on the body surface using a computer processed ECG in 19 dogs. Bipolar XYZ leads were signal averaged (SA) and processed with a bi-directional, 60 Hz high-pass, digital filter. During sinus rhythm, epicardial, transmural and endocardial mapping was performed to identify areas of delayed activation. After each map the chest was closed and a 300 beat SA performed. Eight animals were studied prior to and up to 100 minutes after MI. Before MI, the QRS duration by SA was 60 $\pm$ 5 msec (mean $\pm$ SD). After acute MI, all dogs had fractionated electrograms lasting 119 $\pm$ 13 msec after QRS onset. The maximum delay was from epicardial sites. In all cases, SA detected a low amplitude tail of high frequency energy at the end of the QRS, with a peak amplitude of 2.4 $\pm$ 2.0 μV, lasting 61 $\pm$ 17 msec, and ending 115 $\pm$ 13 msec after QRS onset. The duration of the fractionated activity varied with time. There was a good correlation (r=0.91, 34 pairs) between total ventricular activation time and total SA signal duration. Fractionated electrograms were detected on the body surface which arose from epicardial areas as small as 1 cm^2. In 11 other dogs, studied 3 hrs to 5 days after MI, fractionated activity was seen in 3 and detected on the body surface of those dogs. No evidence of slow ventricular activation was seen in the other 8 dogs, either by ventricular mapping or by SA.

Conclusion: With advanced signal processing, slow ventricular activation after myocardial infarction can be reliably detected on the body surface.

ENDOCARDIAL PACE-MAPPING TO LOCALIZE THE ORIGIN OF VENTRICULAR TACHYCARDIA
Mark E. Josephson, MD, FACC; Harvey L. Waxman, MD; Michael E. Cain, MD; Leonard N. Horowitz, MD, FACC; John A. Kastor, MD, FACC, University of Pennsylvania School of Medicine, Philadelphia, Pa.

Intraoperative epicardial pace-mapping (PM) has been proposed as a method of identifying the origin of ventricular tachycardia (VT); however, limitations of both epicardial activation and ECG morphology in localizing VT origin have been demonstrated. Since most VT associated with ischemic heart disease appear to arise near the endocardium, we evaluated the ability of bipolar catheter endocardial pacing (1 cm interelectrode distance) at or near the endocardial site of origin of VT to mimic QRS morphology and/or ventricular activation pattern of VT. We studied 10 patients (pts) with VT in whom the origin was determined by catheter endocardial mapping and in 6/10 confirmed at surgery. One pt had VT with two distinct morphologies. The 12 lead ECG of VT was compared to the 12 lead ECG produced by pacing the site of origin (8 pts) and multiple other sites in five pts. In the remaining two pts, limited ECG leads and activation times to one or two ventricular reference electrograms during VT were compared to those recorded during pacing the site of origin. We observed that: 1) pacing the known site of VT origin produces a similar ECG and activation sequence as VT; 2) the ECG of VT could not predict the origin; 3) pacing from sites in close proximity to site of VT origin could produce either a similar or a grossly different ECG pattern than during VT. We conclude that catheter endocardial PM: 1) is a corroborative method of identifying VT origin, and 2) may be useful in pts with non-inducible VT or rapid VT who cannot undergo catheter or intraoperative mapping.

ESTIMATION OF VENTRICULAR TRANSMEMBRANE ACTION POTENTIAL DURATIONS AND REPOLARIZATION TIMES FROM UNIPOLAR ELECTROGRAMS
R.F. Wyatt, B.S.; M.J. Burgess, M.D.; A.K. Evans, Ph.D.; R.L. Lux, Ph.D.; J.A. Abildskov, M.D., F.A.C.C. and T. Tsutsumi, M.D.; University of Utah, Salt Lake City, Ut.

A method for estimating ventricular transmembrane action potential (TMAP) durations, depolarization times (T_D) and repolarization times (T_R) from unipolar electrograms (UE) was developed. The method was based on assumptions that minimum derivative of the QRS and maximum derivative of the T in UE correspond to T_D and T_R respectively, and that TMAP duration equals the interval between T_D and T_R. To test these assumptions, UE, bipolar electrograms (BE), and in vivo TMAPs were recorded in 8 dogs during paced cycle lengths (CL) of 300 to 650 ms stepped in 50 ms increments, during coronary occlusion (CO) and release (CR), and during epinephrine infusion (EI). Refractory periods (RP) were measured with extrastimuli during changes in CL. Data were pooled. Correlation coefficients (r) and standard error of estimates (SEE) between TMAP durations measured from in vivo recordings and those estimated from UE, BE and RP are shown below. SEE is given in ms.

	UE		BE		RP	
Intervention	r	SEE	r	SEE	r	SEE
CL	.83	11	.77	13	.55	34
CO	.89	15	.76	26	-	-
CR	.92	11	.90	13	-	-
EI	.89	26	.75	31	-	-
all	.85	16	.77	21	.55	34

The high correlation between estimates of TMAP duration from UE and measurements from in vivo TMAP recordings indicates UE can be used to study TMAP duration at multiple sites and during rapidly changing states in the intact heart.

ENDOCARDIAL MAPPING OF TRIGGERED AUTOMATICITY IN CANINE ISCHEMIC PURKINJE FIBERS

Nabil El-Sherif, MD, FACC; William B. Gough, PhD; Robert Zeiler, MS, Rahul Mehra, PhD, Downstate and VA Medical Centers, Brooklyn, N.Y.

Ventricular arrhythmias seen 24 hours following myocardial infarction (MI) in dogs have been recently shown to be due to triggered automaticity (TA) in ischemic depolarized Purkinje fibers (PF) (El-Sherif et al, Circulation, In press). Utilizing a standard microelectrode technique and endocardial preparations from 24-hour-old MI in dogs TA automaticity arose from a delayed after-depolarization (DAD) and TA stopped when a DAD failed to reach threshold. In quiescent preparations TA was consistently induced by a critical cycle length during regular pacing or premature stimulation and only when DAD attained threshold. To further identify the mechanism of TA we analyzed endocardial activation patterns utilizing a 16-electrode grid with an interelectrode distance of 1-2mm and a multiplexer recording system. Simultaneous recordings of extracellular unipolar electrograms were obtained and isochronic activation maps were constructed. When stimulation of a normal endocardial site initiated TA, the latter was localized to ischemic endocardium. Critical analysis of endocardial activation pattern of the stimulated beat that initiated TA failed to show evidence of reentrant activation. In some preparations background slow automaticity was able to initiate faster TA. Analysis of isochronic maps showed that sudden acceleration of rate was associated with shift of the pacemaker site with the fast TA arising from ischemic endocardium. We conclude that TA in ischemic PF and not reentrant activation is the common mechanism of ventricular arrhythmias seen in dogs 24 hours following MI.

AM
DRUG INTERVENTION IN ACUTE MYOCARDIAL ISCHEMIA
8:30-10:00

PAIN RELIEF IN ACUTE MYOCARDIAL INFARCTION BY INTRAVENOUS ATENOLOL

David R. Ramsdale, MRCP; Eric B. Faragher, FSS; David H. Bennett, MRCP; Colin L. Bray, FRCP; Christopher Ward, MRCP; Salim Yusuf, MBBS; Peter Sleight, FRCP, The Regional Cardiac Centre, Wythenshawe Hospital, Manchester, U.K.

The cardioselective beta-blocker atenolol (AT) was given intravenously (IV) in a double-blind study to assess pain relief after acute myocardial infarction (AMI). Eighteen patients were randomly allocated to treatment with 5mg AT (0.5mg/ml) or 10mls 0.9% saline intravenously immediately after admission, followed by 50mg AT or matching placebo orally 10 mins later. Heart rate (HR), blood pressure (BP) and "pain score" were recorded before and at intervals after injection. These parameters were unchanged by IV saline but were significantly reduced after IV AT as shown below. (Values are mean ± SD)

	Pre.AT	1hr.post AT	p value
HR (bpm)	67±9	58±12	< 0.05
HR x syst. BP (bpm x mmHg)	9350±1010	6620±1670	< 0.05
Pain score	2.60±1.00	0.50±0.40	< 0.01

These results were supported by an open study of 22 patients with AMI receiving IV (5-15mg) AT plus 50mg AT orally during the first hour after admission. Seventeen patients obtained pain relief together with reduction in HR and BP, in contrast to the five remaining patients who did not achieve any reduction in these parameters.

CONCLUSIONS. Patients with AMI can obtain pain relief with IV AT given immediately after admission and this is usually related to achieving a reduction in HR and BP.

ESTIMATION OF VENTRICULAR REPOLARIZATION DURATION AND DISPARITY FROM DISTRIBUTIONS OF QRST AREA

R.L. Lux PhD; J.A. Abildskov, MD, FACC; R.F. Wyatt, BS; A. Kerry Evans, PhD; M.J. Burgess, MD. University of Utah, Salt Lake City, Utah

Disparity of ventricular repolarization contributes to ventricular arrhythmia vulnerability and is also a major factor in determining QRST deflection area (AQRST). Previous evidence that arrhythmia prone states can be identified by AQRST distributions has not included direct documentation of disparate repolarization. Although AQRST has been shown to be a measure of the gradient of recovery properties, no relation to absolute repolarization duration (RD) has been established. New evidence using direct RD measurements suggests use of cycle (CL) might permit practical estimates of RD and its disparity. RD and AQRST were determined from 75 unipolar, epicardial electrograms in each of 6 open-chest dogs, for up to 4 different activation orders and 4 to 6 CL with range 300-900 ms. RD was measured from times of minimum derivative in QRS to maximum derivative in T which we have shown correlates with transmembrane action potential duration. AQRST was calculated by integrating each electrogram over the QT interval. Mean and variance of RD increased with increasing CL confirming prolongation and increased disparity at slow rates. Mean and variance of AQRST also increased with CL in electrograms as well as 192 body surface leads recorded during the same pacing modes prior to thoracotomy. At each CL, RD and AQRST were negatively correlated [-.8<r<-.4] with standard errors of 4-8 ms across all activation orders. RD range was 140-290 ms. Findings suggest AQRST distributions from extensively sampled electrograms can provide practical estimates of RD as well as its disparity. The clinical implication is that measured AQRST distributions may be used to estimate CL corrected values of RD and its disparity.

THE EFFECTS OF NITROGLYCERIN ON INTRACORONARY PLATELET AGGREGATION AND VENTRICULAR VULNERABILITY DURING PARTIAL CORONARY STENOSIS

Peter R. Kowey, MD; Richard L. Verrier, PhD, FACC; Bernard Lown, MD, FACC, Robert I. Handin, MD. Cardiovascular laboratories, Harvard School of Public Health, and Harvard Medical School, Boston, Mass.

Partial coronary stenosis (PCS) has been shown to cause phasic myocardial ischemia and enhanced vulnerability to ventricular fibrillation. The objectives of this study were to determine whether nitroglycerin (NTG) afforded protection during PCS and to delineate the mechanism for the observed protective effects. We induced PCS of the left circumflex vessel in 10 chloralose-anesthetized dogs, utilizing an externally applied plastic cylinder. Seven of these animals manifested spontaneous cyclical reductions in coronary blood flow (CBF) of from 30 to 80% (mean 55%). These reductions in CBF were accompanied by a decline in the ventricular fibrillation threshold (VFT) (43 ± 3 to 21 ± 3 ma, $p < 0.001$). Infusion of NTG (80 µg/min) caused a fall in mean arterial blood pressure of 15 ± 4 mmHg. Within 5 minutes of the start of the infusion, cyclical flow changes ceased and VFT returned to control values. NTG decreased ADP-mediated platelet aggregation from 46 ± 4 to 23 ± 2 Born units ($p < 0.01$) and prevented the occurrence of irreversible platelet aggregation. Administration of the antiplatelet agent, indomethacin (5 mg/kg), caused similar resolution of changes in vulnerability induced by cyclical changes in CBF. We conclude that NTG prevents myocardial ischemia and enhancement of vulnerability during partial coronary stenosis. These effects may be related to the drug's antiplatelet action.

FREQUENCY OF PROVOKED CORONARY ARTERIAL SPASM IN PATIENTS WITH RECENT TRANSMURAL MYOCARDIAL INFARCTION

Michel E.Bertrand,MD,FACC;Jean M. Lablanche,MD;PierreY. Tilmant,MD;Marc G.Delforge,MD;Alain G.Carré,MD
University hospital,Hopital Cardiologique,Lille,France

Provocative test with methergine(M) was performed in a group of 88 patients (pts)(82 men & 6 women)with recent (<6 weeks)transmural myocardial infarction(MI)who underwent coronary arteriography for evaluation of vessel disease.The diagnosis of MI was established by typical chest pain ,appearanceof new Q waves and increase in serum creatine kinase toa level above normal limits. 58 pts or 66% had anterior infarction,28 (32%)had inferior infarction and 2 lateral infarct.Coronary arteriography was performed 26±9 (m±SD) days after the onset of infarc--tion(range6 to 45).37 or 42% had 1 vessel disease (VD), 25 (28%)had 2 VD,19 or 22% had 3 VD whilst 7 had minimal but insignificant lesions.The provocative test was perfor med after the routine procedure of coronary arteriography using a protocol with a single bolus injection of 0.4 mg of methergine.Aortic pressure ,EKG and coronary arteriograms of the 2 vessels (left and right coronary artery) were repeated 3 and 5 minutes later.
Provoked coronary arterial spasm was observed in 18 or 20.5% of patients.9 patients or 10.25% had spasm superimposed on narrowings located on the vessel responsible of the infarction.In these cases spasm was not accompanied by pain or EKG changes.Nine other patients (10.25%)had provoked coronary arterial spasm located on a vessel which was not responsible of the infarction.In this group spasm was accompanied by pain and EKG changes.
Conclusion:1-Provoked coronary arterial spasm can be induced in 20 % of pts with recent MI .2-The vessel with the narrowing responsible for the infarction remains sensitive to methergine in 10% of cases.3-In 10% of cases spasm can be induced in vessel unrelated to MI.

NIFEDIPINE THERAPY FOR RECURRENT ISCHEMIC PAIN FOLLOWING ACUTE MYOCARDIAL INFARCTION

Peter H. Stone, M.D. and James E. Muller, M.D., Harvard Medical School, Brigham & Women's Hospital, Boston, MA.

Following acute myocardial infarction (MI) patients often experience recurrent episodes of ischemic pain at rest which may be due to coronary vasospasm. In order to determine the efficacy of nifedipine, a potent coronary vasodilator, in relieving rest ischemia, we administered nifedipine to 9 patients (pts) with recurrent rest pain a mean of 9.2 days post MI (range 2-42 days). Prior to MI, all of the pts had a history of exertional angina only, yet following the MI episodes of recurrent ischemia occurred at rest (mean # daily episodes 2.4, range 2-6) in spite of maximal medical management with β-blockers and/or nitrate preparations. Six of the 9 pts had a subendocardial MI, 3 had a transmural MI. Ischemic episodes were associated with ST-segment (ST) deviations in the same leads that displayed the acute MI pattern: 5 pts had ST elevation, 4 pts had ST depression or T inversion. Coronary angiography in 6 pts demonstrated multivessel coronary disease. In all pts the episodes of rest ischemia ceased following the initiation of nifedipine (mean daily dose 60 mg, range 40-120 mg). Two pts continued to have myocardial ischemia with minimal exertion and underwent coronary bypass surgery for pain relief. The other 7 pts have been managed medically for a mean of 5.4 months (range 1-12 months) and have remained pain free on combined regimens of nifedipine, β-blockers, and/or nitrate preparations. We conclude that nifedipine may be efficacious for the relief of recurrent myocardial ischemia at rest following acute infarction. In some pts nifedipine may eliminate the need for coronary artery bypass surgery and in others it may provide clinical stability prior to operation.

IMPORTANCE OF EARLY ADMINISTRATION OF INTRAVENOUS NITROGLYCERIN TO PRESERVE ISCHEMIC MYOCARDIUM

John T. Flaherty,MD,FACC, Bernadine H. Bulkley,MD,FACC, Myron L. Weisfeldt,MD,FACC, James L. Weiss,MD,FACC, Gary Gerstenblith,MD,FACC, Clayton Kallman,ScM, Lewis C. Becker, MD,FACC, Johns Hopkins Medical Institutions, Baltimore, Md.

Intravenous nitroglycerin (IV TNG) improves hemodynamics and regional ischemia in patients (pts) with acute myocardial infarction (AMI). In a prospective randomized trial, 48 hr infusion of IV TNG or Placebo (PLAC) was begun within 18 hr of onset of AMI in 104 pts to determine whether a prolonged infusion could preserve ischemic myocardium. IV TNG was titrated to lower mean arterial pressure 10%. Time between onset of pain and initiation of study drug (<or>10hr) defined early and late intervention. ^{201}Thallium perfusion scans and Tc^{99m} gated blood pool scans were performed on days 1 and 10. Thallium defects were scored by computer and were considered improved if a ≥ 2.5 unit reduction in score was obtained (range -11.0 to +5.6). Response of ejection fraction (EF) was considered good if EF remained ≥50% in pts with initial EF≥50% (31 pts) and good if EF increased ≥5% in pts with initial EF<50% (20 pts).

Defect Score	TNG<10 hr	TNG>10 hr	PLAC<10 hr	PLAC>10 hr
Improved	12	2	3	2
Not Improved	12	13	15	11
EF Response				
Good	17	9	7	4
Bad	1	4	6	3

Only in TNG <10 hr subgroup was there significant improvement in defect score (P=.032). Likewise for EF only in the TNG<10 hr subgroup was the beneficial effect significant (P=.056). These results demonstrate that early administration of IV TNG is important for improving myocardial perfusion and preserving function following AMI.

REDUCTION IN INFARCT SIZE AND MORBIDITY BY EARLY INTRAVENOUS BETABLOCKADE

Salim Yusuf, MB BS; David Ramsdale, MRCP; Richard Peto, MSc; Paulo R.F. Rossi, MD; Lynnette Furze,SRN; David Bennett, MRCP; Colin Bray, FRCP; Peter Sleight, FRCP. Department of Cardiovascular Medicine, John Radcliffe Hospital, Headington, Oxford

400 patients were studied in a randomised trial to determine whether administration of intravenous Atenolol (AT) (a cardioselective betablocker) within 12 hours of chest pain reduces eventual infarct size, morbidity and mortality. Infarct size and morbidity data (first 214 patients). 135 patients already had ECG evidence of infarction at entry: 72 received AT which significantly decreased subsequent cumulative MB-CPK release from 4-hourly measurements (intravenous AT and Control means = 121 I.U., SE ± 10 and 176 I.U., SE ± 17; $2p<0.005$) and enhanced R-wave preservation (mean R-wave score in AT and Control = 46% ± 3 and 36% ± 3; $2p < 0.02$). 79 patients had no evidence of infarction at entry; 44 did not receive AT and 27 of these subsequently developed infarction, whereas only 11 of the 35 treated patients infarcted during their hospital stay ($2p < 0.01$). In hospital fewer AT patients had non-fatal cardiac arrest (2 versus 6) or required therapy for heart failure in hospital (36 versus 47, $2p < 0.10$) or at discharge (19 versus 31, $2p < 0.05$). Mortality (400 patients): 14 AT patients and 24 Control patients have died since the start of the study ($2p < 0.10$). Conclusion: Intravenous Atenolol within 12 hours of pain prevents infarction in patients with initial threatened infarcts, and reduces infarct size and morbidity in Acute Myocardial Infarction.

INTRAVENOUS AND ORAL AMRINONE THERAPY IN REFRACTORY HEART FAILURE: HEMODYNAMICS, EXERCISE RESULTS, AND SIDE EFFECTS
James H. Chesebro, M.D., F.A.C.C.; Carlos E. Harrison, M.D., F.A.C.C.; S. L. Deets. Mayo Clinic, Rochester, MN

Fourteen patients, age 40-76, 11 males, with cardiomyopathy (9 dilated, 5 ischemic) and refractory heart failure symptoms at rest and/or minimal exertion were treated with Amrinone by intravenous bolus (IVB), intravenous infusion (IVI) at 10 µg/kg/min, and orally at 1.6-4.0 mg/kg q8h. Hemodynamic monitoring was done before (pre) and for the first 3-8 days of therapy (Rx). The mean values ± standard error of the mean for cardiac index (CI, l/min/m^2), mean pulmonary artery wedge pressure (PWP, mm Hg), stroke volume index (SVI, ml/m^2), systemic resistance (R_S, units m^2), heart rate (HR), and mean arterial pressure (MAP, mm Hg) are listed below.

	CI	PWP	SVI	R_S	HR	MAP
Pre-Rx	1.8±.09	28±2.6	19±1.5	47±2.6	99±5.2	81±4.2
IVB-Rx	3.0±.13	21±2.3	32±2.5	27±1.9	95±4.1	76±4.7
IVI-Rx	3.0±.20	20±2.1	32±2.8	26±1.8	97±4.4	76±3.4
Oral-Rx	2.9±.23	19±2.3	30±2.7	28±1.9	100±3.9	79±3.3

In all 14 patients all 3 CI measurements on Rx were higher than pre-Rx ($P<.001$). In all patients this reproducibility held for PWP and R_S decreases and SVI increases ($P<.001$). For HR and MAP no reproducible pattern or significant change occurred ($P>0.1$). Naughton protocol treadmill exercise capacity (increasing 1 MET every 2 min) increased an average of 285 sec after 8-44 days on Amrinone in 4 of 6 patients able to walk. Platelet counts decreased in all patients by 88,000/mm^3 (avg) after 1 week of Rx, decreased to <100,000/mm^3 in 7 patients (associated with prolonged IVI Rx or oral Rx ≥3.0 mg/kg q8h in 6 of 7 patients) with no associated signs or symptoms, and improved in 2-4 days by decreasing the Amrinone dose. In conclusion, Amrinone is a promising potent inotrope, exhibits no hemodynamic tolerance up to 8 days of Rx, and can be used in doses not associated with thrombocytopenia.

HEMODYNAMIC AND METABOLIC EFFECTS OF TERBUTALINE IN PATIENTS WITH SEVERE HEART FAILURE
R.Y.C. Wang, MBBS, MRCP; P.K. Lee, MBBS, MRCP; D.Y.C. Yu, MBBS, FRCP; T.F. Tse, MBBS, MRCP; M.S.S. Chow, Pharm.D., Queen Mary Hospital, University of Hong Kong, Hong Kong.

To assess the hemodynamic and metabolic effects of terbutaline, a B_2 selective agonist, we evaluated 6 patients with severe heart failure secondary to ischemic heart disease by right and left cardiac and coronary sinus catheterizations. All other drugs were withheld prior to the study. Terbutaline was administered intravenously by constant infusion at 0.3 ug/kg/min for 30 minutes followed by 0.15 ug/kg/min for 60 minutes. The mean values ±S.D. are shown for heart rate (HR, beats/min), mean arterial pressure (MAP, mmHg), cardiac index (CI, L/min/m^2), stroke index (SI, ml/beat/m^2), pulmonary artery wedge pressure (PAW, mmHg), systemic vascular resistance (SVR, dynes sec cm^5/m^2), myocardial lactate extraction (EX_L,%) and myocardial oxygen extraction (EX_{O2},%). *P<0.05, #P<0.001.

	Control	30 min	60 min	90 min
HR	85±15	98±17*	96±16	96±20
MAP	87±17	87±20	82±20	88±22
CI	1.9±0.8	3.1±1.2*	3.0±1.2*	2.9±1.6*
SI	21.8±6.5	30.7±8.1*	30.7±8.4*	28.8±10
PAW	28.0±7.7	16.0±6.8*	15.8±5.1*	15.7±6.2*
SVR	1487±471	946±377#	938±440#	1125±529#
EX_L	19±41	24±26	28±24	26±29
EX_{O2}	61±8	63±12	64±10	62±11

The results of the study indicate that intravenous terbutaline produces beneficial hemodynamic effects without deterioration of myocardial metabolism as indicated by EX_L and EX_{O2}. The drug may prove to be a useful agent for patients with heart failure due to coronary artery disease.

ACUTE EFFECTS OF AMRINONE (5-AMINO-3,4'-BIPYRIDIN-6(1H)-ONE) ON SYSTEMIC BLOOD FLOW DISTRIBUTION.
Stanley Einzig, MD and Mary Ella Pierpont, MD; University of Minnesota; Minneapolis, Minnesota.

Amrinone (AM), a new cardiotonic agent, is used to treat refractory heart failure. However, the effect of this drug on blood flow (BF) in different vascular beds is unknown. We investigated the effect of AM on CO and on myocardial, cerebral, renal, intestinal, hepatic (arterial), pancreatic and skeletal muscle BF ("15" micron radionuclide labeled spheres) in 15 anesthetized dogs. Measurements were made during control (C) conditions, and 5 and 60 min. following intravenous AM injection. At 5 min. following AM at 1 mg/kg (n=7): mean Ao pressure was reduced by 8 mmHg from 118±7 (SE) mmHg ($P<0.01$); CO was unchanged from the C value of 125±8 ml/kg/min; LV and renal cortical BF were increased by 30% and 16% from C values of 1.07±0.05 and 6.12±0.24 ml/g/min, respectively ($P<0.05$ and $P<0.01$); and cerebral, intestinal, hepatic, pancreatic and skeletal muscle BF were unchanged from C values of 0.35±0.03, 0.56±0.14, 0.14±0.04, 0.29±0.04 and 0.04±0.01 ml/g/min, respectively, ($P>0.05$). The transmural distribution of LVBF (ie, Endo/Epi ratio) was reduced (1.08±0.03 vs 0.91±0.03, $P<0.002$). Similar changes in BF were present in dogs receiving 2 mg/kg (n=8), despite a greater reduction in mean Ao pressure (ie, 27 mmHg). At 60 min. post AM, LV and renal BF had returned to C values in both groups of dogs and the LV Endo/Epi ratio returned to 1.0. These studies suggest that with the exception of transient alterations in myocardial and renal perfusion, AM has minimal effects on systemic BF distribution under our experimental conditions.

THE EFFECT OF TERBUTALINE ON RIGHT AND LEFT VENTRICULAR FUNCTION AND SIZE IN OBSTRUCTIVE LUNG DISEASE.
Wayne Hooper, M.D., Robert Slutsky, M.D., Dale Kocienski, M.D., Kathy Witzum, M.D., Roger Spragg, M.D., William Ashburn, M.D., and Kenneth Moser, M.D., University of California, San Diego, Ca.

Terbutaline (T) is relatively B2 specific. T has been shown in CAD and COPD to increase LVEF and C.O. Its effects on RV function are not known. Eleven patients with severe COPD ($\overline{FEV_1}$=46%, MMEF .28) were studied by equilibrium radionuclide angiography before and serially after .25mgm T s/q. Six patients had depressed RVEF (<.45) before T.

	Control	25-30	50-60	115-120*
LVEF	.63±.03	.76±.03†	.72±.03†	.65±.03
LVEDV	106± 9	84± 9 †	94± 9	104± 9
LVSV	64± 5	61± 5	63± 5	66± 5
RVEF	.39±.03	.54±.03†	.52±.03†	.45±.03
RVDVU	3.58±.15	2.91±.15	2.88±.15	2.97±.15

(Statistics are mean ± SEM; *minutes after T; †p<.05 vs control; LVEDV=LV end diastolic volume; LVSV=LV stroke volume; RVDVU=RV diastolic volume units).

Serial values of expiratory flow rates after T did not change. There was no change in LVSV and an insignificant increase in cardiac output (↑10%) despite an increase in heart rate (↑14%, p<.01). Mean and diastolic blood pressures decreased (p<.05). While the RVDVU did not appear above to have significantly decreased, when examined at the time of peak increase in RVEF, the RVDVU had diminished (p<0.01) compared to before T. Therefore, T increases LVEF and RVEF while decreasing LV and RV size. We conclude that T may be potentially beneficial in COPD patients for its hemodynamic effects (inotropy, afterload reduction) despite its adverse chronotropic effect and lack of flow rate improvement in certain patients.

COMPARATIVE CARDIOCIRCULATORY ACTIONS OF NEW SELECTIVE BETA-1 AGONIST PRENALTEROL VS DOBUTAMINE: DEMONSTRATION OF EQUIVALENT BENEFICIAL EFFECTS ON CARDIAC PUMP PERFORMANCE IN CONGESTIVE HEART FAILURE

Kathleen Needham, BS; Najam A. Awan, MD, FACC; Mark K. Evenson, BS; Zakauddin Vera, MD, FACC; Dean T. Mason, MD, FACC, University of California, Davis.

To evaluate the efficacy of the new positive inotrope selective beta-1 receptor agonist prenalterol (PN) in therapy of severe chronic congestive heart failure (CHF) we compared the hemodynamic effects of intravenous PN (4mg) with dobutamine (DB; 10μg/kg/min) in 7 severe CHF patients. Measurements included: HR=heart rate, bpm; MBP=mean blood pressure, mmHg; LVFP=left ventricular filling pressure, mmHg; CI=cardiac index, L/min/M^2; SI=stroke index, ml/beat/M^2; SWI=stroke work index gm·m/M^2; TSVR=total systemic ventricular resistance, dsc^{-5}. Drug vs Control (C): * = p<0.01, + = p<0.001.

	HR	MBP	LVFP	CI	SI	SWI	TSVR
C	84	83	20	1.97	24	21	1702
PN	86	79	19	2.62*	30+	26*	1260+
C	87	84	20	1.99	24	22	1861
DB	92	79	18	2.76*	30*	27*	1223*

Therefore PN and DB equally raised LV pump function: prenalterol increased CI 24% while dobutamine elevated CI 27%,($p>0.05$). Moreover blood pressure, left ventricular filling pressure and heart rate were unchanged with both agents. These positive inotropic actions of PN were not accompanied by increased ventricular ectopy. Thus the beta-1 agonist prenalterol safely produces dobutamine-like salutary augmentation in cardiac function in patients with severe congestive heart failure. Importantly the availability of an oral formulation of prenalterol provides potential beneficial ambulatory therapy in patients demonstrating salutary acute responses. Thereby the new positive inotrope prenalterol is useful for therapy of severe congestive heart failure.

ACUTE AND FOLLOW-UP STUDIES WITH PIRBUTEROL IN HEART FAILURE

J.R. Dawson, MRCP; S. Reuben, PhD; P.A. Poole-Wilson, MD G.C. Sutton, MD, FACC, Hillingdon Hospital and Cardiothoracic Institute, London, U.K.

Pirbuterol, a beta-agonist with vasodilator and positive inotropic properties, has been investigated in 59 patients with chronic heart failure (NYHA Class III/IV). Hemodynamic measurements were made by Swan-Ganz catheter and cardiac output by thermodilution. The results represent values for control and peak response using various doses of pirbuterol(10-40mg). CI increased from 2.1±0.1 l/min/m^2 to 3.0±0.1 l/min/m^2 ($p<0.001$), left ventricular filling pressure (LVFP) and systemic vascular resistance(SVR) both fell from 25±1.5mm/Hg. to 19±1.5 mmHg. ($p<0.001$) and from 1830±70 dynes/sec/cm^5 to 1330±60/dynes/sec/cm^5 ($p<0.001$) respectively. Heart rate and blood pressure did not change. Subsequently patients began long-term treatment with pirbuterol 20mgs t.i.d. During preliminary follow-up (mean 4 months), 16 patients (27%) died; 11 of intractable heart failure, 3 suddenly, 1 from pulmonary embolism and 1 from a non-cardiac cause. 15 patients were withdrawn, 10 for lack of efficacy, the others because of side effects. 16 patients had repeat studies at 3 months. CI was 2.8±0.2, LVFP 17±4 and SVR 1350±150 all significantly improved from their initial control values ($p<0.001$). These indices were unchanged following a further challenge with pirbuterol(20mgs) suggesting that a maximal response had already been attained. Acute administration of pirbuterol improves pump performance, an effect which is sustained in some patients on long-term treatment. The high incidence of death and withdrawal in follow-up probably reflects the severity of disease in the population studied.

RECANALIZATION OF OCCLUDED VESSEL DURING ACUTE PHASE OF MYOCARDIAL INFARCTION
10:30-12:00

TRANSLUMINAL RECANALIZATION DURING EVOLVING MYOCARDIAL INFARCT IN MAN.

Hiltrud S. Mueller, MD, FACC; Dennis J. Gory MD, FACC; David M. Harshman, MD; Carey M. Marder, MD; Pulipaka B. Rao, MD; Robert Roth, RN; J. Gerard Mudd, MD. St. Louis University, Dept. of Medicine; St. Louis, MO

Coronary recanalization was attempted in 7 patients (pts) 3-5 hrs after clinical onset of myocardial infarct (MI). Group A: 2 pts with 100% and 2 pts with 99% obstruction (Obs) of the proximal RCA, unresponsive to nitroglycerin, underwent successful thrombus perforation, resulting in some antegrade flow. Intracoronary streptokinase (Stk) infusion (2000-4000 U/min) for 60 min improved Obs to 95, 90 and 40% with complete filling of the distal vessel. Reperfusion was associated with decrease in ST elevations, improvement of segmental wall motion, early appearance and peak of creatine kinase-MB and ventricular irritability. Follow-up: Segmental wall motion was improved to mild hypokinesis in 2 pts, to normal in 2 pts. Group B: Thrombus perforation was unsuccessful in 1 pt with 100% mid LAD Obs and in 2 pts with 99% mid LAD or 99% proximal CCA Obs. Thrombus perforation was unsuccessful because of inability to selectively catheterize the diseased vessel. Stk infusion did not change Obs; infarct related left ventricular segments remained akinetic. Lack of reperfusion might be related to non-selective infusion of Stk into the main LCA. Infusate was probably redistributed mainly in the normal left coronary system. Follow-up: Progression of 99% Obs to complete Obs in 2 pts. Prior akinetic segments remained severely hypokinetic. Conclusions: (1) Early reperfusion can salvage myocardial function. (2) Lysis of thrombus is more effective if preceded by perforation. (3) Stk infusion selectively into the obstructed artery appears necessary. (4) Reperfusion is associated with ventricular irritability and enzyme washout.

THE "REFLOW" AND "NO-REFLOW" MYOCARDIAL INFARCTION.

Edward H. Schuster, M.D., Alison Freifeld, B.A., and Bernadine H. Bulkley, M.D., F.A.C.C., The Johns Hopkins School of Medicine and Hospital, Baltimore, Maryland.

It is known that after acute myocardial infarction (MI) a variable amount of reflow to the ischemic area may occur; and, that contraction band (CB) necrosis is a histologic marker for reflow. To determine how reflow affects clinical and pathologic features of the acute infarct, we studied 31 autopsied patients with acute MI and histologic evidence of sizeable reflow (defined as > 30% of total infarct being CB necrosis) and compared them to 39 with little or no-reflow (< 30% of infarct, CB necrosis). Comparing these 2 groups, there was no significant difference in age, sex, initial Killip class, blood pressure, primary ventricular arrhythmias, or heart block; and at autopsy no difference in heart weight, location or number of MI's, or extent of coronary artery disease. Patients with reflow MI's had less Q wave infarcts (12/31 vs 29/39, $p < .005$), more hypotensive episodes prior to the MI (13/31 vs 5/39, $p < .01$), smaller infarcts (16% LV vs 23% LV, $p < .05$), and shock or congestive heart failure as a less frequent cause of death than no-reflow MI's (9/31 vs 24/39, $p < .005$). Thrombi were found more frequently in the no-reflow patients (31/39 vs 8/31, $p < .005$). Of the patients with reflow infarcts, 28/31 had a patent coronary that fed the infarcted myocardium as opposed to only 9/39 patients with no-reflow MI's ($p < .005$).

The morphologic distinction of these 2 types of infarcts is compatible with the clinical concept of the occlusive thrombotic (no-reflow), and the spasm or hypoperfusion MI (reflow). Moreover, the morphologic data suggests that reflow may be associated with more arrhythmias, but greater myocardial salvage.

DISSOLUTION OF CORONARY ARTERY BYPASS GRAFT THROMBI BY STREPTOKINASE INFUSION

Geoffrey O. Hartzler, MD, FACC; Warren L. Johnson, Jr., MD, FACC: David R. McConahay, MD, FACC; Barry D. Rutherford MD, FACC, Mid America Heart Institute, St. Luke's Hospital, Kansas City, MO

Early post-operative(post-op)coronary artery bypass graft thrombosis may result in unstable angina requiring urgent reoperation. We report initial experience with thrombus dissolution by direct graft infusion of strepokinase at 26 hrs(pt 1)and 1½ hrs(pt 2)following onset of symptoms. Arteriography seven days post-op in pt 1(72 yo male) revealed total occlusion of the proximal right coronary artery(RCA) and RCA graft. Following guide wire penetration of the thrombus-filled graft, streptokinase, 10,000 units bolus and 1200 units/min, was infused for 90 min through a pre-formed brachial coronary catheter. Serial arteriography documented progressive thrombolysis, increasing distal graft visualization, and return of flow within the RCA. Death occurred 36 hrs later. Post-mortem examination showed extensive recent inferior and old anterior infarctions but patent RCA graft. Ten days post-op, arteriography in pt 2(66 yo female)revealed total occlusion of the proximal left anterior descending artery(LAD)and subtotal thrombotic occlusion of the LAD graft. Streptokinase was infused for 90 min through a 3.5 F transfemoral catheter positioned within the graft body. Gradual but partial thrombolysis resulted with relief of ischemic pain at 30 min and resolution of ST segment depression. Continued treatment with anti-platelet agents & anticoagulants resulted in near complete disappearance of thrombus and marked improvement in anterior wall contractility at arteriography 10 days later. We conclude that dissolution of acute graft thrombi by direct infusion of streptokinase is technically feasible. Additional studies will be required to define the clinical role of this technique.

SALVAGE OF JEOPARDIZED MYOCARDIUM BY NON-SURGICAL REPERFUSION (NSR) IN MAN

Peter Rentrop, MD; Heiner Blanke, MD; Karl R. Karsch, MD, Med. Univ. Hospital, Göttingen, W.-Germany

Biplane LV cineventriculography was performed sequentially in 18 infarct pts., in whom reperfusion was achieved within 8 ± 7 hrs after onset of chest pain by intracoronary infusion of streptokinase (SK) (2000 U/min) (A). EF was 51.4 ± 9.8 % prior to reperfusion and 54.8 ± 8.9 % after completion of SK-infusion ($p < 0.025$); length of the AKS decreased from 10.2 ± 6.1 cm to 7.1 ± 4.9 cm ($p < 0.025$). LVEDP decreased from 21 ± 9 to 18 ± 7 mmHg ($p < 0.025$). Inspection during bypass surgery in 10 pts. 40 ± 23 days after reperfusion and microscopic examination of transmural myocardial biopsies in 3 pts. revealed the bulk of reperfused myocardium to be viable. Hemodynamic data prior to reperfusion and in the chronic stage of MI (prior to aortocoronary bypass surgery) were compared with data of a retrospectively matched group of conventionally treated pts. (B) who had acute angiography at a time when NSR was not yet available. Control angiography in the chronic stage showed: persistent occlusion of infarct vessel(B_1, n=9), spontaneous recanalization of initially obstructed infarct vessel (B_2, n=9).

		A	B_1	B_2
EF (%)	acute	49.9 ± 12	52 ± 6.6	51 ± 8.1
	chronic	57.4 ± 12.7	43.4 ± 7.6	52 ± 12.2
AKS (cm)	acute	9.2 ± 6.2	7.7 ± 4.0	9.1 ± 4.9
	chronic	4.5 ± 6	9.8 ± 5.5	7.1 ± 6.9

×=p<0.025

Aneurysm formation occurred in 3 Co- and 2 Cr-pts., but not in Group A. Preservation of R-waves was more extensive in Group A. The data demonstrate improvement of LV function early after NSR and suggest that jeopardized myocardium was salvaged.

LYSIS OF CORONARY ARTERY THROMBOSIS WITH INTRACORONARY STREPTOKINASE IN ACUTE MYOCARDIAL INFARCTION

Lawrence A. Reduto, MD, FACC; Richard W. Smalling, MD, PhD; Gregory C. Freund; K. Lance Gould, MD, FACC; University of Texas Health Science Center, Houston, TX.

Intracoronary (IC) infusion of streptokinase (SK) at 2000 Iu/minute was performed in 11 patients (pts) with acute transmural myocardial infarction (AMI) at (mean±SD) 10±4 hours following onset of chest pain (range 4-15 hours). Lysis of coronary artery thrombus by IC SK relieved the total occlusion responsible for AMI in 8 pts by 30 minutes of SK infusion. Three pts had high grade (>50% reduction in luminal diameter) stenosis without total obstruction. Angiographic left ventricular (LV) ejection fraction (EF), LV end-diastolic pressure (EDP), LV stroke volume (SV) and LV stroke work index (SWI) pre and post IC SK were as follows:

	PRE		POST	p
EF(%)	42±13	(range 28 to 67)	48±12	ns
EDP(mmHg)	26±8	(range 17 to 41)	32±11	ns
SV(cc/beat)	55±34	(range 24 to 113)	53±18	ns
SWI(gm-m/M^2)	48±23	(range 25 to 87)	41±8	ns

Moreover, LVEF determined with gated cardiac blood pool imaging did not change from immediately post IC SK to hospital discharge (52±16% vs 52±15%, p=ns). Two pts demonstrated improvement in segmental wall motion abnormalities following lysis of coronary thrombus with increase in LVEF of 24% and 13%. LVEF increased by 12% in two additional pts without change in segmental wall motion abnormalities. These data suggest 1) IC SK resulted in lysis of coronary artery thrombus in pts with AMI 2) Indices of global LV performance do not significantly (p=ns) change in most pts with AMI either immediately post IC SK or at hospital discharge when studied at a mean of 10 hours post chest pain.

INTRACORONARY STREPTOKINASE IN ACUTE MYOCARDIAL INFARCTION: ASSESSMENT BY Tl-201 SZINTIGRAPHY

Gerhard Schuler,Klaus v. Olshausen, Helmut Mehmel, Jochen Senges, Jochen Manthey, Wolfgang Mäurer, Wolfgang Kübler,FACC; Med. Uni-Klinik,Heidelberg,Germany

Intracoronary infusion of streptokinase (S) has been advocated as a means to salvage jeopardized myocardium in acute coronary occlusion. We used seven-pinhole Tl-201 tomography to study the effect of this intervention in 10 patients (pt) with electrocardiographic evidence of acute myocardial infarction and less than 4 hours of chest pain. There was no history of previous infarction in any pt. Coronary cineangiography (CA), performed prior to S, showed occlusion of one major coronary artery branch associated with a dyskinetic area. Restitution of flow was achieved in 9 pts; in 1 pt S failed to reestablish flow. Szintigrams were obtained before (CONTROL) and following S at 24 hours and 4 weeks. At CONTROL a large perfusion defect was present in all pts; at 24 hours two groups of pts could be identified: in 7 pts there was only marginal reduction of infarct size as compared to CONTROL although reflow was achieved as early as 2.5 hours after onset of symptoms. In these pts CA failed to demonstrate collateral coronary circulation supplying the infarcted area. However, in two pts with extensive collaterals there was marked improvement of Tl-201 uptake. Both groups did not differ significantly in time from onset of symptoms to reestablishment of flow. No change was noted in one pt in whom the vessel remained occluded. At 4 weeks only insignificant additional improvement of Tl-201 uptake was noted. We conclude: Lysis of acute coronary thrombosis is readily accomplished by S in most pts; however significant reduction of infarct size as assessed by Tl-201 szintigraphy seems to be largely dependent on the presence of collateral circulation.

SURGERY FOR CORONARY ARTERY DISEASE—2
10:30-12:00

FACTORS AFFECTING MORTALITY AFTER MITRAL VALVE REPLACEMENT COMBINED WITH CORONARY BYPASS GRAFTING

Bernard Gersh, MD, FACC; Francisco J. Puga, MD; Ronald E. Vlietstra, MD, FACC; Lila R. Elveback, PhD; Steven L. Yeager, MD; William D. Edwards, MD; Gordon K. Danielson, MD, FACC; James R. Pluth, MD, FACC, Mayo Clinic, Rochester, MN.

At the Mayo Clinic from 1972-1978, the 30-day mortality for isolated mitral valve replacement (MVR) was 5.3% (41 of 779), whereas that for MVR plus coronary bypass graft surgery (CABG), 1970-1978, was 13.3% (10 of 75). The aim of this study was to identify by multivariate methods the factors resulting in the high early mortality in the MVR plus CABG group. Clinical, laboratory, and surgical variables were included. There was a major difference between the sexes: the females were older, had more severe coronary artery disease (CAD), had a smaller proportion of diseased vessels grafted, and had a higher early mortality (8 of 22 or 36% versus 2 of 53 or 4% for males). Nine of the 10 early deaths could be identified by means of 3 factors: the Gensini measure of the severity of CAD, the adequacy of left coronary revascularization, and the presence of LV aneurysm. This combination of variables correctly classified 91% of the patients. For rheumatic or ischemic etiology (n=47), the early mortality was 20%, whereas CAD was less severe and there were no deaths in patients with primarily degenerative mitral valve disease (n=20). For the 65 30-day survivors, the subsequent 3-year survival was 71% (51% in females, 76% in males). The cardiothoracic ratio was the only variable that discriminated between late deaths and the 3-year survivors. We conclude that the early mortality of MVR plus CABG is markedly influenced by the extent of CAD and the adequacy of revascularization. Late mortality, however, is predominantly affected by ventricular function.

CORONARY ANGIOGRAPHY AND CORONARY ARTERY BYPASS SURGERY IN ELDERLY PATIENTS

Bernard Gersh, MD, FACC; Robert L. Frye, MD, FACC; Richard A. Kronmal, PhD; Elizabeth Cardis, BS; Thomas J. Ryan, MD, FACC; Arthur J. Gosselin, MD, FACC; George Kaiser, MD, FACC; Thomas Killip III, MD, FACC, and all participants in the Coronary Artery Surgery Study (CASS).

This study describes 2,035 patients (pts) ≥65 years old with coronary artery disease entered in the CASS registry and the complications of coronary angiography and bypass surgery (CABG) in this group. Ages ranged from 65-82 years; 73% were males. The predominant symptom was angina pectoris in 86% and cardiac failure in 6%. In 51%, angina pectoris was unstable. Angiography documented triple-vessel disease in 53%, double-vessel in 26%, and single-vessel in 17%. Disease of the left main coronary artery (≥50% stenosis) was present in 15%. Ejection fraction was <50% in 32% of pts. Complications of angiography included death in 0.25%, nonfatal myocardial infarction in 0.6%, and neurologic complications in 0.5%. CABG alone was performed in 997 pts (49%), with a hospital mortality of 5%. Pts were divided into three age groups: 1, 65-69 years; 2, 70-74 years; and 3, ≥75 years. Results were as follows:

No. of pts	Group	Hospital surgical mortality
735	1	4.5%
221	2	6.3%
41	3	9.8%

We conclude that in patients ≥65 years of age, the mortality of coronary angiography is low whereas that of CABG is increased in comparison with a 1.8% hospital mortality in 6,438 CASS pts <65 years old.

HYPERLIPOPROTEINEMIA (HLP) AS A SIGNIFICANT RISK FACTOR FOR PULMONARY EMBOLISM (PE) IN CORONARY ARTERY BYPASS (CABG) PATIENTS

Eric C. Hanson, MD and Frederick H. Levine, MD
Massachusetts General Hospital, Boston, MA 02114

Although PE is a rare complication following cardiac surgery, a notable association of PE in hyperlipoproteinemic patients following CABG procedures prompted us to define the incidence of PE in this group. A retrospective study of all patients suffering PE following cardiac surgery from 1975 through 1979 was undertaken and lipoprotein profiles of these patients were evaluated. Of over 4,800 patient records, 26 patients (19 male, 7 female) were identified who presented with the definite clinical, laboratory, and radiologic evidence of PE in the post-operative period. Twenty had undergone coronary artery bypass grafting, and the remaining six had undergone other cardiac procedures. Of the 20 CABG patients, 19 (95%) were found to have HLP (14 Type II patients, 70%; 5 Type IV patients, 25%). Only one of the six other patients had HLP, a patient who had an aortic arch aneurysm resection who was Type II. There were four hospital deaths (4/26, 15%), all related to PE and all were Type II patients who had undergone CABG procedures. Since patients with HLP comprise less than 10% of our CABG population the incidence of PE in this group is highly significant ($p<.001$). Experimental evidence has shown that patients with HLP, especially Type II, have increased platelet adhesiveness and clotting abnormalities consistent with a hypercoagulable state. This retrospective study clinically confirms that finding and suggests that early postoperative anticoagulation therapy in patients with HLP, particularly Type II, may be indicated to reduce thromboembolic complications.

IMPROVED GRAFT PATENCY WITH ANTIPLATELET DRUGS IN PATIENTS TREATED FOR ONE YEAR FOLLOWING CORONARY BYPASS SURGERY.

B Greg Brown, MD,PhD, Ramon A Cukingnan, MD, Lacy Goede, BS, Maylene Wong, MD, Henry Fee, MD, Jack Roth, MD, John Wittig, MD, Joseph Carey, MD, Wadsworth VA Hosp, UCLA, L.A., CA.

Does antiplatelet therapy (APT) improve saphenous vein graft patency? 147 consecutive patients (pts) were enrolled in a randomized, doubly blinded, risk-stratified, prospective trial comparing aspirin 325 mg tid plus dipyridamole 75 mg tid (A/D), or aspirin (A), with double placebo (P). 123 patients completed surgery, drug initiation 67±27 (SD) hours post-op, 5 clinic visits, and recath at one year. Overall predictors of graft patency were coronary lumen diameter at the point of anastomosis (D_{an}), the % proximal stenosis in the grafted artery (%S), graft flow (Q_g), and the % reactive hyperemia (%RH) after a 15 second graft occlusion. Results, in terms of assigned therapy (AR_x): APT did not benefit grafts to arteries with $D_{an} \leq 1.5$mm, or grafts with $Q_g \leq 40$ml/min or with %RH ≥ 15% above baseline flow. But a substantial trend in favor of APT (A or A/D) was seen in the overall group. Strong favorable trends or statistically significant benefits were seen in certain large subsets. All grafts were patent in 57% of 44 pts on P, 73% of 37 pts on A, and 63% of 42 pts on A/D.

	GRAFT OCCLUSION FREQUENCY (NO. OF GRAFTS AT RISK IN GROUP)			
AR_x	All Grafts	D_{an}>1.5mm	Q_g>40ml/min	%RH<15%
P	21.1%(147)	18.8%(112)	22.8% (101)	33.8% (71)
A	12.2%(115)	8.2%* (85)	9.5%+ (84)	17.2%* (58)
A/D	16.3%(135)	10.4% (96)	8.3%‡ (84)	20.0% (65)
APT	14.4%(250)	9.4%+ (181)	8.9%‡ (168)	18.7%+ (123)

χ^2 comparison of drug with P: *=p<.05, +=p<.02, ‡=p<.01

The most common and generally most important subsets of diseased arteries are those with D_{an}>1.5mm or which require Q_g>40ml/min. Antiplatelet therapy reduces by 50-61% the early occlusion of grafts to those arteries. Thus post-op APT is recommended, unless contraindicated, for most bypass patients.

THE CLINICAL USEFULNESS AND FEASIBILITY OF DETERMINING CORONARY ARTERY BYPASS GRAFT PATENCY BY CONTRAST ENHANCED COMPUTED TOMOGRAPHY DURING THE EARLY POSTOPERATIVE PERIOD

Charles R. McKay, MD; Bruce H. Brundage, MD, FACC; Robert J. Herfkens, MD; Martin J. Lipton, MB, ChB, FACC; Kevin Turley, MD, FACC; Daniel J. Ullyot, MD, FACC; Paul A. Ebert, MD, FACC, University of California, San Francisco, Ca.

Eight male patients (PTS) with severe coronary artery disease received 20 saphenous vein coronary artery bypass grafts (CABG). Soon after surgery (6 of 8 PTS within 4 days of surgery), graft patency was evaluated by contrast enhanced computed tomography (CT) using a peripheral vein for injection of contrast medium. In 4 of the 8 PTS the following clinical situations raised the question of early graft occlusion: recurrent ventricular fibrillation with myocardial infarction, recurrent pericardial tamponade, low intraoperative graft flow measurements and a friable aorta which required 1 complex "Y" graft with 2 vein-to-vein anastomoses to bypass 3 vessels. All studies were completed within 1 hour and were well tolerated by the PTS without significant morbidity. CT scans demonstrated that all 20 grafts were patent, and eliminated early graft occlusion as a clinical problem in these PTS. The study shows that CT imaging of CABG in the early postoperative period is easy to perform, has no significant morbidity, and yields clinically useful information. Recognition of graft occlusion within 48 hours of surgery should be possible with this technique. Assessment of CABG in the early postoperative period by CT may be a useful reference for repeat CT studies in the long term follow-up of these PTS.

ATRIAL TACHYCARDIA. THE PAROXYSMAL VERSUS THE PERMANENT FORM.

Hein J.J. Wellens, MD, FACC; Pedro Brugada, MD; David Ross, MD; Frits W.H.M. Bär, MD; Eddy J.D.M. Vanagt, MD; Willem R.M. Dassen, PhD, Dept. of Cardiology, University of Limburg, Annadal Hospital, Maastricht, The Netherlands

In 12 consecutive patients(P) with atrial(A) tachycardia (T) A mapping, initiation(I) and termination(Te) of T by programmed stimulation(PS) and the effect of carotid sinus massage(CSM), Atropine (9P) and Verapamil (10P) were studied. In 7P T originated in the A septum, in 4P in the right and in 1P in the left atrium. In 7P T was paroxysmal (group 1), in 5P T was permanent (group 2). P of group 1 were older than group 2 ($p<0.001$). There were no differences in sex or heart rate during T. In all P of group 1 and none of 2 I and Te of T was possible by PS, in all P of group 2 T could be reset during PS. CSM terminated T in all P of group 1 and one of group 2. Atropine (1mg i.v.) accelerated T in 4/6 P of group 1 and 3/3 of group 2. Verapamil (10mg i.v.) slowed or terminated T in 5/6 P of group 1 and had no effect (2/4P) or accelerated T (2/4P) in group 2. Exercise accelerated AT in 4/4 P of group 2. Conclusion: 1) AT of the paroxysmal form fulfills criteria for a re-entry or triggered automaticity mechanism and can be suppressed by vagal manoeuvres and drugs. Follow-up study showed complete suppression of paroxysmal AT by drugs. 2) AT of the permanent form seems to be based on abnormal automaticity. The area of impulse formation can be invaded and reset but T cannot be terminated by PS, vagal manoeuvres or drugs. Follow-up study showed failure to suppress T by any of the existing drugs.

INOTROPIC CONTRACTILE RESERVE: A USEFUL PREDICTOR OF INCREASED FIVE YEAR POSTOPERATIVE SURVIVAL AND IMPROVED LEFT VENTRICULAR FUNCTION IN PATIENTS WITH CORONARY ARTERY DISEASE AND A DEPRESSED EJECTION FRACTION

Richard Nesto, MD; Lawrence H. Cohn, MD, FACC; John J. Collins, Jr., MD, FACC; Joshua Wynne, MD, FACC; B. Leonard Holman, MD, FACC; Peter F. Cohn, MD, FACC, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

The increase in ejection fraction (EF) produced by post-extrasystolic potentiation or epinephrine infusion (PESP/EPI) has been used to demonstrate inotropic contractile reserve (ICR) in patients with coronary artery disease and a depressed EF (<.50). Prior studies have shown that $\Delta EF \geq .10$ after PESP/EPI is helpful in discriminating those patients with better short term (1 yr) prognosis whether treated medically or surgically. Because no data are available concerning long term follow-up, the present study related ICR to 5 yr postoperative prognosis in 35 patients receiving PESP/EPI between 1971-74. LV function was assessed with radionuclide ventriculograms whenever possible. Results are as follows:

	$\Delta EF \geq .10$		$\Delta EF < .10$
No. of patients	20		15
Early deaths (<2 mo)	2		6
Late deaths (≥2 mo)	2		4
5 yr survival	16/20 (80%)	p<.01	5/15 (33%)
Radionuclide ventriculograms	6		3
Increase in EF from preoperative contrast LV gram (mean ± SEM)	.20 ± .05	p<.01	0 ± .08

Thus, ICR, as demonstrated by $\Delta EF \geq .10$ after PESP/EPI, is a useful predictor of increased 5 yr postoperative survival and improved LV function in patients with coronary artery disease and a depressed EF.

Disopyramide Phosphate in Wolff-Parkinson-White Syndrome.

Charles R. Kerr, M.D.; Eric N. Prystowsky, M.D., F.A.C.C.; Warren M. Smith, M.D.; John J. Gallagher, M.D., F.A.C.C. Duke University Medical Center, Durham, North Carolina.

We evaluated the electrophysiological effects of disopyramide phosphate(DP) in 12 patients with Wolff-Parkinson-White syndrome(WPW). Electrophysiological studies were done during a control period, following intravenous DP, and after 4 days on oral DP (1000-1200 mg/day). Reciprocating tachycardia and atrial fibrillation(AF) were induced in all patients. The cycle length and ventriculo-atrial interval during reciprocating tachycardia and the shortest and mean RR intervals during AF are shown in the following table (mean ± SD). P values are comparisons to control.

	Control	Intravenous DP	Oral DP
Cycle length (msec)	331±53	342±57	370±68*
V-A interval (msec)	118±44	127±45**	151±63**
AF-Shortest RR (msec)	169±18	226±24***	248±36***
AF-Mean RR (msec)	225±58	329±62**	360±93***

* $p < 0.025$, ** $p < 0.005$, *** $p < 0.001$

Following DP the episodes of AF were shorter and self-terminating. Despite prolonging the cycle length of reciprocating tachycardia, DP did not prevent its induction. Accessory pathway refractoriness prolonged following oral DP in all 6 patients in whom it could be assessed. No acute hemodynamic side effects were observed but 4 patients developed gastrointestinal or anticholinergic side effects on oral DP. Seven patients elected to have surgical interruption of their accessory pathways while 5 have been successfully treated with oral DP. Thus DP appears to have beneficial electrophysiological effects in patients with WPW. The ventricular response during AF is markedly slowed through prolonged refractoriness in the accessory pathway and the cycle length of reciprocating tachycardia is lengthened through slowed conduction in the pathway.

CHARACTERIZATION OF THE ONSET OF ECTOPIC ATRIAL TACHYCARDIA WITH A-V BLOCK.

Joaquin G. Arciniegas, MD; Vance J. Plumb; Albert L. Waldo, MD, FACC, University of Alabama in Birmingham, Birmingham, Alabama

Ectopic atrial tachycardia with A-V block (EAT) is a poorly understood rhythm. We analyzed the onset of 52 episodes of spontaneous EAT occurring in 9 patients free of digitalis toxicity. All patients were originally in sinus rhythm. During these episodes, bipolar atrial electrograms (AEG) were recorded simultaneously with at least one surface ECG lead. To establish the presence of EAT, the rhythm had to have a cycle length less than 273 msec (220 beats/min), an isoelectric segment between P waves and evidence of A-V block at some time during the tachycardia. Three distinct patterns of onset of EAT were appreciated. In 6 instances, EAT was preceded by transient atrial fibrillation of variable duration (12 to 20 seconds). In 4/6, gradual regularization of the AEG during atrial fibrillation occurred. In 2/6, EAT abruptly replaced atrial fibrillation. In 15 instances, EAT started de novo, the cycle length of the 1st beat being the same as the cycle length of the EAT. In 31 instances, EAT was started by a late premature atrial beat (coupling interval 74-88% of the preceding sinus cycle). This was followed by progressive shortening of the cycle length of the 2nd and 3rd beats of EAT, followed by regularization of the EAT at a longer cycle length than that of the 3rd beat. In this latter group, the principles of traditionally accepted mechanisms (automaticity and reentry) of arrhythmias are not followed. These data show a close interrelationship between EAT and atrial fibrillation and also suggest that more than one underlying mechanism of EAT may exist.

ATRIAL EXCITABILITY AND CONDUCTION IN PATIENTS PRONE TO ATRIAL FIBRILLATION

Ross J. Simpson, Jr., MD; James R. Foster, MD; Leonard S. Gettes, MD, University of North Carolina, Chapel Hill, N.C.

Atrial fibrillation occurs frequently in patients (pts) with prolonged P waves. To test the hypothesis that abnormalities of atrial excitability or conduction are found in these patients, we defined atrial strength interval curves, late diastolic threshold, and the conduction time of early and late premature beats in 7 pts with P waves of < 115 msec (Group I) and 13 pts with P waves ≥ 115 msec (Group II). The increase in conduction time of early compared to late premature beats was measured from the high right atrium to low septal right atrium (A_{HRA}-A_{HIS}) and coronary sinus (A_{HRA}-A_{LA}). Only Group II patients had abnormal sinus node function (3/13) or history of atrial fibrillation (6/13).

The conduction time of premature beats in late diastole was similar in both groups. In Group I pts the conduction time of early premature beats increased slightly. In Group II pts conduction time of early premature beats increased dramatically and the difference between the maximum increase in conduction time of Group I and Group II pts was significant (A_{HRA}-A_{HIS}: 5±10 vs 30±20, $p<.005$; A_{HRA}-A_{LA}: 5±15 vs 30±15, $p<.05$).

Late diastolic threshold was lower in Group I than in Group II pts (0.8±2 vs 1.3±2, $p<.005$). There was no difference between Group I and II in latency, refractory periods or presence of an early diastolic "supernormal" excitable period.

Conclusion: The marked conduction slowing of early atrial premature beats in patients with large P waves may explain their propensity to atrial fibrillation.

SINUS NODE FUNCTION AFTER CARDIAC TRANSPLANTATION

Alan F Mackintosh MRCP; David J Carmichael MRCP; Christopher Wren MRCP; Terence A English FRCS; Michael C Petch MD, Papworth Hospital, Cambridge, England

Cardiac transplantation produces a permanently denervated donor sinus node and provides an opportunity for studying the human sinus node separated from the autonomic nervous system. Twelve patients have received transplants at Papworth Hospital and temporary atrial epicardial wires were used in 6 to explore sinus node function during the first 3 weeks after operation. On most days recordings were made of the cycle length, the sinus node recovery time (SNRT), and the sinoatrial conduction time (SACT) calculated by pacing slightly faster than the spontaneous rate for 9 beats.

For the first 4 days the rhythm was unstable and all 6 patients demonstrated abnormal nodal function. After this period 2 patients showed a stable atrial rhythm with normal SNRT and SACT. Another patient temporarily developed a slow junctional rhythm soon after pacing associated with a prolonged SACT; both returned to normal after 9 days. These 3 patients are alive. The other 3 patients showed less stable rhythms. The SNRT was often markedly prolonged (maximum 12 seconds) and pronounced secondary slowing occurred after pacing. These 3 patients have died. One died while undergoing ambulatory monitoring; the tape showed progressive bradycardia leading to asystole after 16 minutes. One collapsed in circumstances suggestive of a fatal arrhythmia and the third died from uncontrolled rejection.

In our experience sinus node dysfunction can occur after transplantation and when present may be particularly dangerous as the normal escape mechanisms seem unreliable.

ENHANCED VAGAL TONE SHORTENS ATRIAL REFRACTORINESS AND FACILITATES INDUCTION OF REPETITIVE ATRIAL RESPONSES IN MAN.

Eric N. Prystowsky, MD, FACC; Gerald V. Naccarelli, MD; Warren M. Jackman, MD; Robert L. Rinkenberger, MD; James J. Heger, MD; Douglas P. Zipes, MD, FACC, Krannert Institute of Cardiology, Indiana University School of Medicine and V.A. Medical Center, Indianapolis, Indiana.

Although enhanced vagal tone (EVT) decreases atrial refractoriness in animals, published data on effects of ouabain and atropine suggest the opposite may occur in man. The purpose of this study was to determine the effect of EVT on right atrial effective (ERP) and functional (FRP) refractory period in man. Twelve patients (pts) had electrophysiology study using standard intracardiac techniques. A specially made collar connected to a vacuum source was placed around the pt's neck. EVT was produced during neck suction using intracollar negative pressures (INP) of -50 to -60 mmHg. INP, induced for 2 seconds during sinus rhythm, increased spontaneous sinus cycle length from 837 ± 96 to 1136 ± 273 msec (mean ± 1SD, $p<.001$). Atrial ERP and FRP were determined before and during application of INP. Atrial ERP and FRP significantly decreased during INP (241 ± 24 to 230 ± 20 msec, $p<.01$, and 272 ± 32 to 262 ± 29 msec, $p<.01$ respectively). During refractory period determinations, repetitive atrial responses were induced in 3 pts and occurred only during EVT. Systemic arterial blood pressure remained constant during INP. After atropine (0.03 mg/kg IV) no decrease in atrial refractoriness occurred during INP (2/2 pts). In conclusion: 1) EVT mediated via muscarinic receptors shortens atrial ERP and FRP in man, and 2) facilitates induction of repetitive atrial responses; 3) the neck collar provides a method to evaluate the effects of EVT on electrophysiologic properties in man.

VENTRICULAR ARRHYTHMIAS II: LOCALIZATION OF FOCUS AND TREATMENT
10:30-12:00

ACTIVATION MAPPING IN SINUS RHYTHM IN PATIENTS WITH VENTRICULAR TACHYCARDIA-RELATIONSHIP TO CYCLE LENGTH AND SITE OF ORIGIN

Scott R. Spielman, MD; Leonard N. Horowitz, MD,FACC; Allan M. Greenspan, MD,FACC; William J. Untereker, MD, FACC; Michael B. Simson, MD,FACC; John A. Kastor, MD, FACC; Mark E. Josephson, MD,FACC. Hospital of the University of Pennsylvania, Philadelphia, Pa.

Eight patients with 10 morphologically distinct, clinically occurring ventricular tachycardias (VT) and coronary artery disease (CAD) underwent catheter (1 mm and 1 cm interelectrode distances) endocardial activation mapping in sinus rhythm (NSR) at 12-15 left ventricular sites. In all patients fragmented electrograms were recorded within the infarction zones that began within and outlasted the surface QRS by 15-95 msec (m=51.6±30.4). The cycle length of each VT (range 250-450 msec m=346±64.5) was directly related to the duration of activation in the longest local endocardial electrogram in NSR (range 100-170 msec m=137.5±26.1) with r=.807 ($p<.005$). The endocardial electrogram with the longest duration of fragmented activity was at the site of origin of 8/10 VTs. Epicardial mapping at 35-65 sites was also performed in NSR at the time of arrhythmia surgery in all 8 patients. Late epicardial potentials were only observed in 1 patient and were distant from the site of origin.

We conclude that fragmented electrograms recorded by catheter endocardial mapping identify areas of slow conduction that may participate in or be a final common pathway for the reentrant circuit in patients with VT-CAD.

SURGICAL THERAPY FOR RIGHT VENTRICULAR TACHYCARDIA

Jay W. Mason, MD, FACC; Edward B. Stinson, MD, FACC; David L. Ross, MD; Kaylyn Bockemuehl, RN, Stanford University Medical Center, Stanford, CA.

Four patients, 2 women ages 20 and 25 and 2 men 26 and 58 years, with recurrent right ventricular tachycardia (VT) which was resistant to therapy with 5 or more antiarrhythmic agents, including at least one experimental drug, underwent right ventriculotomy and/or myocardial resection at sites of early electrical activity determined by intraoperative activation sequence mapping during ventricular tachycardia. Three patients had right ventricular myocardial disease, characterized by fibrosis, hypertrophy and fatty infiltration, and one (25F) had no identifiable cardiac disease. All had normal left ventricles. The latter patient had a single VT morphology localized to the pulmonary outflow region, where a single 3cm ventriculotomy rendered VT uninducible. The other 3 patients (58M, 26F, 20F) had 3, 6, and 9 VT morphologies respectively, requiring multiple sequential ventriculotomies, full thickness resections or subendocardial resections of the right ventricle at successively identified early sites. None of the four patients had strikingly delayed epicardial electrical activity during NSR and even mildly late activity did not uniformly correspond to early sites during VT. Three of the four patients are free of arrhythmias and drugs 11, 9 and 2 months after surgery; one patient (20F) is now well controlled on encainide at 2 months. We conclude that drug resistant ventricular tachycardia in non-ischemic disease or even in a structurally normal heart can be treated successfully by surgery with mapping; that an as yet poorly understood myocardial disease may involve the right ventricle alone and cause VT; and that multiple VT morphologies are characteristic of this disease.

PROGRAMMED PREMATURE STIMULATION AS A GUIDE TO ANTI-ARRHYTHMIC THERAPY FOR MALIGNANT VENTRICULAR ARRHYTHMIA IN THE ABSENCE OF AMBIENT ECTOPY

Philip J. Podrid, MD, FACC; Arno Schoeneberger, MD; Bernard Lown, MD, FACC; Jeffery Matos, MD; James Porterfield, MD: Elizabeth Corrigan, MD, Cardiovascular Laboratories, Harvard School of Public Health, Boston, MA.

Among 180 patients (PTS) with recurring malignant ventricular arrhythmias (VA), 34 (19%) had little ectopic activity precluding antiarrhythmic (AA) drug testing. These PTS were subjected to programmed premature stimulation (PPS) to provoke multiple repetitive responses (MRVR) defined as 3 or more successive ventricular beats following the premature stimulus. Our aim was to determine if this endpoint rather than long runs or sustained ventricular tachycardia (VT) could be used to select an effective AA program. A right ventricular pacing wire was left in place for 1 to 2 weeks and was employed for PPS utilizing 1 to 3 extra stimuli at both 2x and 3x mid-diastolic threshold. Testing was performed during both ventricular pacing and sinus rhythm. In 30 PTS with MRVR, a total of 236 drug tests were conducted (7.6/pt). In 4 patients MRVR could not be produced. In 25 of the 30 patients MRVR was abolished by one or more AA agents and the AA drug suppressing MRVR was used for chronic maintenance therapy. After a mean followup of 15.6 months (1-29) one patient has had recurrence. Complications were infrequent, with sustained VT occurring in only 6.2% of tests; ventricular burst terminated 3.7% while 2.5% required cardioversion. Ventricular fibrillation was not precipitated. We conclude that PPS utilizing MRVR as an endpoint is as effective as but safer than provoking VT as a guide to AA therapy. It was effective in 25 or 34 PTS (74%) studied.

ELECTROPHYSIOLOGIC STUDIES BEFORE AND AFTER AORTOCORONARY BYPASS IN PATIENTS WITH OUT-OF-HOSPITAL VENTRICULAR FIBRILLATION

Hasan Garan, MD; Jeremy N. Ruskin, MD, FACC; John DiMarco, MD, Cardiac Unit, Massachusetts General Hospital, Boston, MA.

Electrophysiologic studies (EPS) with programmed ventricular stimulation (PVS) were performed in 7 patients undergoing aortocoronary saphenous vein grafting (ACSVG) following out-of-hospital ventricular fibrillation without acute myocardial infarction. Five patients had EPS before ACSVG. PVS induced ventricular fibrillation in 2 patients and nonsustained polymorphic ventricular tachycardia (5-20 beats) in 3 others off all antiarrhythmic drugs. All 7 patients underwent uneventful ACSVG without perioperative myocardial infarction. Two weeks after ACSVG all 7 patients underwent EPS with PVS. Three patients had nonsustained polymorphic ventricular tachycardia with PVS after ACSVG. Two patients had no inducible ventricular arrhythmia during EPS after ACSVG. The remaining two patients had PVS-induced ventricular flutter during EPS after ACSVG. In patients with electrically-induced ventricular arrhythmia after ACSVG, serial EPS with PVS were performed to define effective antiarrhythmic regimen, whereas patients with no electrically-inducible ventricular arrhythmia were discharged off antiarrhythmic drugs. All 7 remained free of arrhythmias with a follow-up period of 2 to 24 months. We conclude that in patients with high grade ventricular irritability the effect of ACSVG on electrical instability is not predictable and pre- and post-op EPS constitute an important port of their evaluation and treatment.

SLOW VENTRICULAR ACTIVATION DETECTED ON THE BODY SURFACE IN PATIENTS WITH VENTRICULAR TACHYCARDIA AFTER MYOCARDIAL INFARCTION

Michael Simson, MD, FACC, Scott Spielman, MD, Leonard Horowitz, MD, FACC, Mark Josephson, MD, FACC, Alden Harken, MD, FACC and John Kastor, MD, FACC, Hospital of the University of Pennsylvania, Philadelphia, PA.

Using advanced ECG processing, we have found a distinctive, low amplitude, high frequency signal in the late QRS which identified patients (pts) with ventricular tachycardia (VT) after myocardial infarction (MI). We studied the origin of that signal in 7 pts with inducible VT after MI using catheter endocardial and intra-operative epicardial mapping during sinus rhythm. All pts had ventricular aneurysms. Twelve left ventricular endocardial sites and 32-54 epicardial sites were studied. Bipolar XYZ ECG leads were signal averaged and processed with a bi-directional, 25 Hz high-pass digital filter.

Low amplitude, delayed, fractionated electrograms were recorded in all pts at 4.6 ± 2.6 sites/pt. All sites demonstrating fractionated electrograms were within the infarcted zone and 87% were endocardial. The fractionated electrograms lasted 89 ± 31 msec and ended 120 ± 36 msec after QRS onset. When analyzed for timing, the fractionated and delayed electrograms corresponded to the low amplitude late QRS signal found on the body surface in 5 pts. The last 40 msec of the QRS contained a higher proportion of fractionated electrograms (78 ± 22%) compared to the rest of the QRS (29 ± 14%, $p<.0001$). Slow conduction could not be detected on the body surface in 2 pts; 1 with left bundle branch block and 1 with brief fractionated electrograms which ended 80 msec after QRS onset.

Conclusion: A low level, high frequency, late QRS signal, which identifies pts with VT, originates from endocardial areas of slow conduction within the infarct zone.

ARRHYTHMOGENICITY OF ENCAINIDE. THE ROLE OF QT INTERVAL.

George B. Bren, MD; P. Jacob Varghese, MD, FACC; Richard J. Katz, MD; Allan M. Ross, MD, FACC; George Washington University, Washington, D.C.

Although Encainide (E) has been an effective agent for suppressing ventricular ectopy, recent reports suggest that some patients may become refractory to E or E may induce ventricular tachycardia (V.T.). Electrocardiograms (E.C.G.) of 8 patients (pts) (age 14-58 years) who were treated with E for refractory V.T. were reviewed to determine whether any of the E.C.G. measurements would be a predictor of continuing electrical instability.
None of the pts was taking any drug which would affect E.C.G. measurements, nor were there any electrolyte abnormalities during E therapy. In all pts P-R, QRS, and QTc intervals were measured before and after E.
In 4 pts (group A) QTc increased from 410 ± 50 msec. to 540 ± 60 msec. ($P < 0.02$) after E with minimum prolongation of 90 msec. In the other 4 pts (group B) QTc did not prolong after E (440 ± 50 to 440 ± 60). In both groups P-R and QRS intervals increased after E but neither measurement was significantly different between the two groups. Daily dose of E was not significantly different between the two groups: group A 262 mg. and group B 238 mg.
All pts in group A showed continuing electrical instability: exercise induced V.T. (2 pts), V.T. during repetitive ventricular stimulation (R.V.S.) (1 pt) and 1 pt had new spontaneous V.T. and V.T. induced by R.V.S. In contrast none of the group B had V.T. during exercise or R.V.S. These results indicate that arrhythmogenicity of E can be predicted by its effect on QTc independent of QRS effects of the drug.

QUANTIFICATION OF VALVULAR REGURGITATION BEFORE AND AFTER MEDICAL AND SURGICAL THERAPY BY RADIONUCLIDE ANGIOGRAPHY.

Joann Urquhart MD, Milton Packer MD, FACC, Randolph Patterson MD, FACC, Steven F. Horowitz MD, FACC, Ken Miceli RT , Richard Gorlin MD, FACC. Mount Sinai Medical Center, New York, N.Y.

A noninvasive method of quantifying valvular regurgitation (VR) to evaluate the results of medical and surgical therapy is needed. Radionuclide gated cardiac blood pool scans (GBPS) were performed in 42 patients (pts): group I (18 pts) had primary VR (aortic or mitral) with good LV function, group II (14 pts) had VR with poor LV function, and group III (10 pts) had no VR. VR was quantified by calculating a regurgitant ratio (RR) of LV to RV stroke counts (enddiastolic minus endsystolic counts in RV and LV regions of interest).

In group I pts, values for RR correlated closely (r=0.95) with measurements of regurgitant fraction derived from simultaneous determination of total and forward stroke volumes during cardiac catheterization. After valve replacement surgery, values for RR in these pts decreased (↓) from 4.03 ± 1.46 to 1.38 ± 0.23 ($p<.001$), a value similar to that observed in group III pts without VR (1.32 ± 0.15). All 3 pts with residual postoperative VR had RR values > 2SD above the mean values for group III (↓ 1.62); the remaining 15 pts without VR had smaller RR values.

In group II pts, treatment with oral hydralazine (H) increased stroke volume index (SVI)(20 to 38 cc/beat/m^2) and ↓ systemic vascular resistance (SVR) (2245 to 915 dynes-sec-cm-^{5}). Simultaneous GBPS showed no significant change in ejection fraction (EF) (.18 to .21) but values for RR ↓ from 3.37 ± 1.24 to 2.12 ± 0.79, $p< .001$. Changes in SVR and SVI with H correlated closely with changes in RR values (r=0.92 and 0.84, respectively) but not with changes in EF (r=0.15 and 0.18).

In conclusion, calculation of RR by GBPS is an accurate noninvasive method of quantifying VR before and after medical and surgical therapy.

PLATELET SURVIVAL TIME AND BETATHROMBOGLOBULIN IN CARDIAC VALVE REPLACEMENT

Alexander G.G. Turpie, M.D., Auke C. de Boer, M.D., Edward Genton, M.D., Rodney Butt, Ping Han, M.D., John Gunstensen, M.D., Hamilton General Hospital and McMaster University, Hamilton, Ontario, Canada.

Abnormal platelet survival time (PST) and betathromboglobulin (BTG) concentration have been reported to identify patients at risk of thromboembolism and to predict response to antithrombotic therapy after cardiac valve replacement. ^{51}Chromium - PST calculated by the exponential model (normal 118 hrs ± 16) and plasma BTG (normal 28 ng/ml ± 8) were measured pre and post replacement of the aortic (AVR, n=39) or mitral (MVR, n=64) valves. Urine BTG (normal 0.18 ng/ml ± 0.18) was measured after MVR. Mean PST pre and post AVR was similar to normal ($p>0.1$), but was reduced pre MVR (98 ± 26 $p<0.05$) and abnormal in 35%, became normal post MVR (109 ± 21) and remained reduced in 8% of patients. Plasma BTG was elevated pre (44 ± 25) and post (36 ± 15) AVR and pre (42 ± 25) and post (50 ± 43) MVR, $p<0.05$. Urine BTG was elevated post MVR (0.30 ± 0.22) and abnormal in 22% of patients. Urine but not plasma BTG concentration correlated with PST (r=-0.51, $p<0.05$). There was no difference in the results between tissue or prosthetic valves at either site. Abnormal platelet tests did not correlate with thromboembolism. BTG was abnormal pre and post AVR and MVR. PST was normal pre and post AVR and was abnormal pre-MVR but usually became normal post-MVR. Neither BTG nor PST have clinical value in the management of patients with valvular heart disease.

PLATELET REACTIVITY IN PATIENTS WITH AORTIC VALVE DISEASE

Jeanne M. Riddle, PhD, Paul D. Stein, MD, FACC, Henry Ford Hospital, Detroit, Michigan

Platelet reactivity was evaluated in 30 patients who required replacement of their aortic valve: 16 had predominant aortic stenosis (AS) and 14 had predominant aortic insufficiency (AI). Electron microscopy was used to determine the amount of cytoplasmic spreading by single platelets and the amount of aggregation that resulted from exposure to a Formvar film in vitro. A hyperactive response was defined as >20% spread type platelets with decreased numbers of dendritic forms and/or increased aggregates (>93 aggregates/100 single platelets). Such platelet reactivity occurred in only 8% (6 of 72) of normal subjects; whereas in patients with aortic valve disease, 60% (18 of 30) showed a hyperactive platelet response ($P < .01$). The number of patients with AS who had hyperactive platelets, 69% (11 of 16) was comparable to the number with AI, 50% (7 of 14) (NS). Patients both with AS and AI had more hyperactive platelets than normal subjects ($P < .01$). The occurrence of hyperactive platelets in patients with AS and AI is compatible with the previous observation of platelet deposition on stenotic valves removed at surgery. Turbulence, high shear stresses, and exposed abnormal surfaces may contribute to the increased platelet reactivity.

ENDOMYOCARDIAL BIOPSY IN PATIENTS WITH LIFE-THREATENING VENTRICULAR DYSRHYTHMIA

Guy S. Reeder, MD; David R. Holmes, MD; Geoffrey O. Hartzler, MD; William D. Edwards, MD; Mayo Clinic and Foundation, Rochester, MN

Patients with "primary" myocardial disease may initially present with cardiovascular collapse due to ventricular tachycardia (VT) or fibrillation (VF). Long term management of survivors might be improved by knowledge of underlying myocardial pathology. To evaluate this, 17 patients (9 males, 8 females, mean age 27 years) underwent endomyocardial biopsy as part of comprehensive evaluation of unheralded VT (10 patients) or VF (7 patients). Coronary arteriography disclosed no obstructive lesion in any patient.

Biopsy results showed that 9 patients (53%) had findings suggesting early cardiomyopathy with prominent interstitial fibrosis, cellular hypertrophy or atrophy. These patients received antiarrhythmic therapy. Five patients (29%) had findings of myocarditis with lymphocytic infiltration and interstitial edema. Four of these patients received steroid therapy; three showed complete resolution of inflammatory changes on serial biopsy, however, in 2 of these 3 patients persistence of dysrhythmia required specific antiarrhythmic drug therapy. Three patients (18%) had normal biopsy findings - one patient in this group had mitral prolapse and another had long QT interval.

We conclude 1) endomyocardial biopsy is helpful in defining underlying pathology in this heterogenous patient population, 2) biopsy is often helpful in selecting appropriate drug therapy especially in patients with unsuspected myocarditis. Further experience is required to determine if biopsy may be used to prognosticate survival or clinical course.

MYOCARDIAL BIOPSY IN PATIENTS WITH VENTRICULAR TACHYCARDIA

Diederik van Hoogenhuyze, MD; Eckhardt Olsen, MD, F.R.C. Path.; Berry Crook, M.R.C.P.; Marcel van de Brand, MD. Zuiderziekenhuis, Rotterdam, The Netherlands.

In most patients(pts) with ventricular tachycardia (VT), an underlying cardiac abnormality can be demonstrated. In some however, extensive investigation does not reveal an apparent cardiac cause. To assess the diagnostic role of myocardial biopsy, multiple(2-7, mean 3.2) endomyocardial catheter biopsies from the RV and/or LV were obtained in 15 pts,(mean age 31,2 yrs, range 21-54). They presented with symptomatic ventricular dysrythmias, and recurrent VT was demonstrated in all by routine ECG or ambulatory monitoring. Only 4 pts had cardiomegaly or signs of heart failure. With clinical examination, non-invasive testing(including echocardiography and exercise test), and right and left heart catheterisation, congenital, valvular and coronary heart disease could be ruled out. LV volume was increased and ejection fraction decreased in 5 pts; the 10 remaining had normal LV function. Coronary angiograms were all normal. Microscopic evaluation of the biopsies was compatible with congestive cardiomyopathy in 9 pts, of whom 6 had normal LV function. Diagnosis was based on a combination of hypertrophied muscle fibers, increased interstitial fibrosis and endocardial thickening. Chronic myocarditis was diagnosed in 4 cases; one biopsy showed extensive fibrosis of unknown etiology and 1 was normal.

Conclusion: 1.Fourteen out of 15 pts, presenting with clinically unexplained VT, had abnormal biopsy findings. 2.The majority of the abnormal biopsies were compatible with a diagnosis of congestive cardiomyopathy. 3.Ventricular dysrythmias may be an indication of congestive cardiomyopathy even in the absence of cardiac enlargement or abnormal function.

THE USE OF TRANSVENOUS MYOCARDIAL BIOPSY TO DIAGNOSE AND ACCURATELY EVALUATE DISEASES OF THE MYOCARDIUM

Joseph E. Parrillo, MD; Thomas Aretz, MD; Igor Palacios, MD; John T. Fallon, MD and Peter C. Block, MD, FACC, Massachusetts General Hospital, Boston, Massachusetts

Transvenous myocardial biopsy (TMB) has been shown to be diagnostically helpful in cardiac transplant rejection, however it has been debated whatever it is useful in evaluating other cardiac diseases. Since 1975, 49 TMBs have been performed at Massachusetts General Hospital to help evaluate a variety of patient with myocardial diseases. Adequate biopsy material was obtained in all 49 patients, and there were no major or minor complications. The TMB was judged as definitely helpful to the clinician in 24 (49%) and probably helpful in an additional 16 (33%) patients. A definitive pathologic diagnosis was made in 16 (33%), and a confirmatory pathologic diagnosis was made in an additional 13 (27%) patients. The TMB pathologic diagnosis was confirmed in 7 or 7 (100%) patients who came to autopsy or surgery. TMB identified several potentially specifically treatable myocardial disease: myocarditis (6 pts.), vasculitis (1 pt.), hypereosinophilic cardiomyopathy (2 pts.), and radiation-induced cardiomyopathy (2 pts.). In 4 of 6 patients with biopsy-demonstrated myocarditis, the clinical picture was not typical of myocarditis and the diagnosis would have been missed if TMB had not been performed. In 15 patients with constrictive/restrictive physiology, TMB was found to be very useful and accurate in differentiating restrictive cardiomyopathy from constrictive pericarditis. When a complete clinical evaluation was combined with TMB, TMB provided diagnostic information that was very frequently of major help to the clinician (definitely or probably helpful in 82%) in the evaluation of a variety of myocardial diseases.

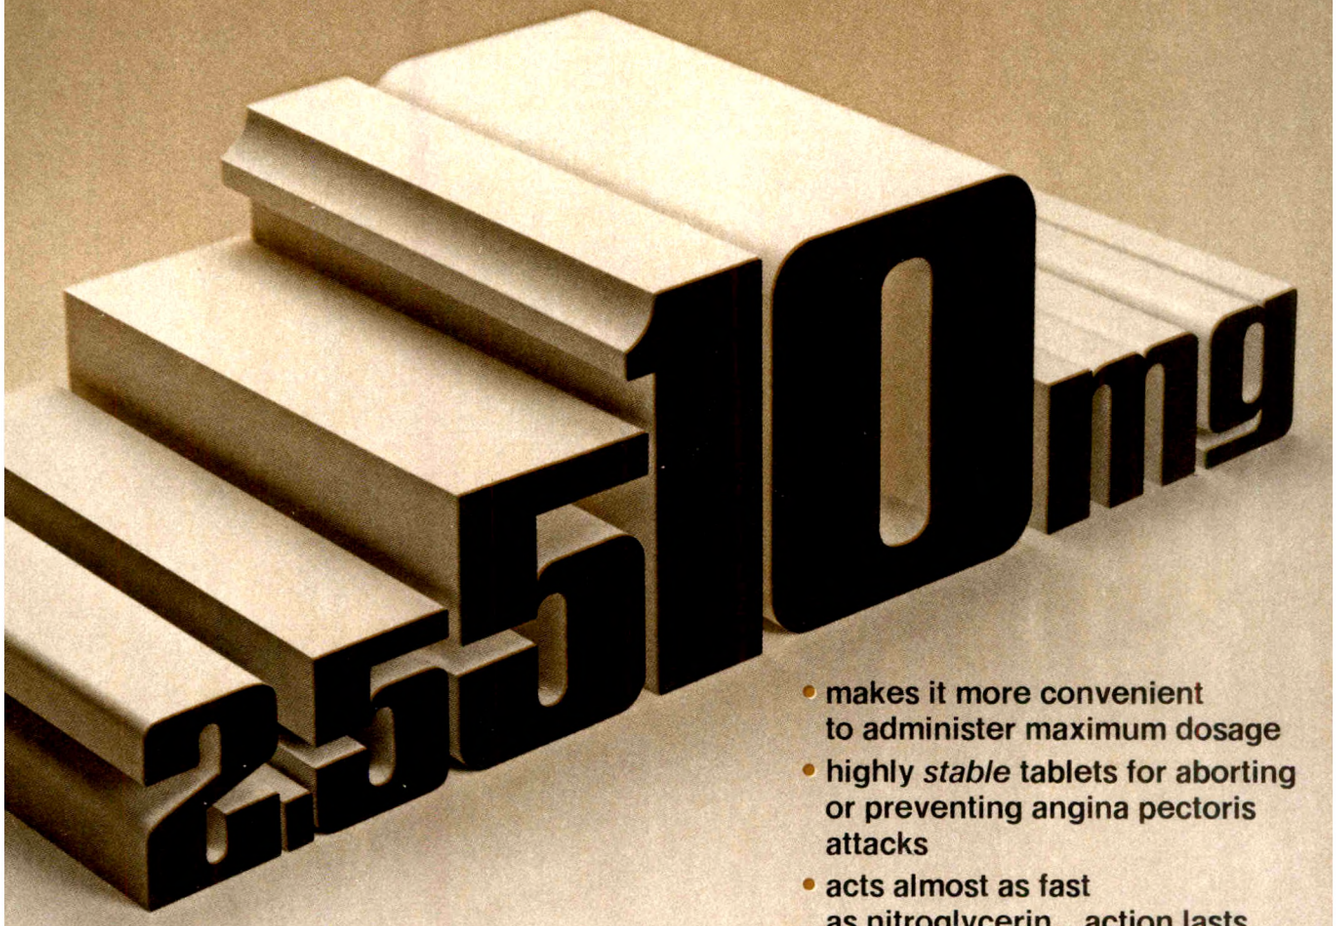
ANNOUNCING

A "step-up" in sublingual angina* therapy



- makes it more convenient to administer maximum dosage
- highly *stable* tablets for aborting or preventing angina pectoris attacks
- acts almost as fast as nitroglycerin...action lasts up to 2 hours

now...10 mg tablet

ISORDIL® SUBLINGUAL

(ISOSORBIDE DINITRATE) SUBLINGUAL TABLETS: 2.5 mg, 5 mg, and now—10 mg

Usual dosage: one 10-mg tablet every 2-3 hours (or prn *after starting at lower dose*)

Tablets shown smaller than actual size.

***Indications:** Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:
"Probably" effective: When taken by the sublingual route, Isordil Sublingual Tablets are indicated for the treatment of acute anginal attacks and for prophylaxis in situations likely to provoke such attacks. Final classification of the less-than-effective indications requires further investigation.

Contraindication: Idiosyncrasy to this drug.

Warnings: Data supporting the use of nitrites and nitrates during the early days of the acute phase of myocardial infarction (the period during which clinical and laboratory findings are unstable) are insufficient to establish safety.

Precautions: Tolerance to this drug and cross-tolerance to other nitrites and nitrates may occur.

and weakness as well as other signs of cerebral ischemia associated with postural hypotension may occasionally develop. This drug can act as a physiological antagonist to norepinephrine, acetylcholine, histamine, and many other agents. An occasional individual exhibits marked sensitivity to the hypotensive effects of nitrite, and severe responses (nausea, vomiting, weakness, restlessness, pallor, perspiration and collapse) can occur even with the usual therapeutic dose. Alcohol may enhance this effect. Drug rash and/or exfoliative dermatitis may occasionally occur.

Dosage and Administration: The basic dosage for Isordil (Isosorbide Dinitrate) Sublingual Tablets is one 5-mg or 10-mg tablet every 2 to 3 hours. The 2.5-mg tablet facilitates adjustment of dosage. All three dosage strengths are used sublingually.

Consult direction circular before prescribing.

IVES LABORATORIES INC. Ives

THE TRENDSETTER™ — The top-of-the-line scanner for integrated ECG, blood pressure and pacemaker evaluation, together with comprehensive alphanumeric/graphic summaries.

VIS-U-SCAN™ — The high-speed system that puts 24 hours of ECG in your hands in three minutes flat without missing a beat.

SMART SCANNERS, SMART VALUES

There's a Del Mar Avionics ECG scanner that satisfies your most exacting requirements — in the hospital or in your office. And a worldwide network of servic centers assures fast, professional response when you need it, where you need it.

An outstanding Education and Training staff rounds out our commitment to excellence. Training courses extend the skills and knowledge of your staff in the appl cation of ECG principles to Holter System data analysis.

Our full line of smart scanners coupled with the extra services only a leader can provide, makes your investment in a Del Mar Avionics system a smart move. Ca your local representative today.

nother reason were called *PACESETTER:*

Pacesetter® Introduce

Interrogatabl

6 3

Programalith 6 is the full six-parameter interrogatable, programmable pacemaker. In conjunction with the Programmer, Programalith 6 provides the physician with the means for comprehensive paced-patient management while obviating many common reasons for invasive pacing system revision.

For less critical applications, Programalith 3 provides the physician with the same basic interrogation capabilities as Programalith 6, as well as three programming functions – pacing rate, pulse width and sensitivity – all with multiple options.

Only after you have reached the ultimate in sophistication can you truly simplify. This new 6-3-1-0 family of Programalith® Interrogatable™ pacemakers is ideal demonstration of that fact. It is the most flexible system ever offered the physician. Even the simplest of these four pulse generators offers the all-important Pacesetter exclusive: a simple method of calculating years of remaining battery capacity as well as an accurate determination of possible problems and their location, through measurement by interrogation of lead and heart interface impedance,

Pacesetter® Sustems, Inc

a Complete Family o
Pacemakers.

1 0

Programalith 1 interrogates and programs a single parameter – pacing rate – allowing the physician to choose from 12 different options and provides the all-important interrogation function as well.

For simplest applications, Programalith 0 requires no programming, yet can still be interrogated for all measur data, providing invaluable assistance in lo term patient management.

battery impedance and battery current. Part of the flexibility of this new system derives from the complete integration of all units with the one single programmer the physician will ever need – the one Pacesetter supplies to you with the first implant of any one of these pacers. No wonder they call us Pace*setter*.

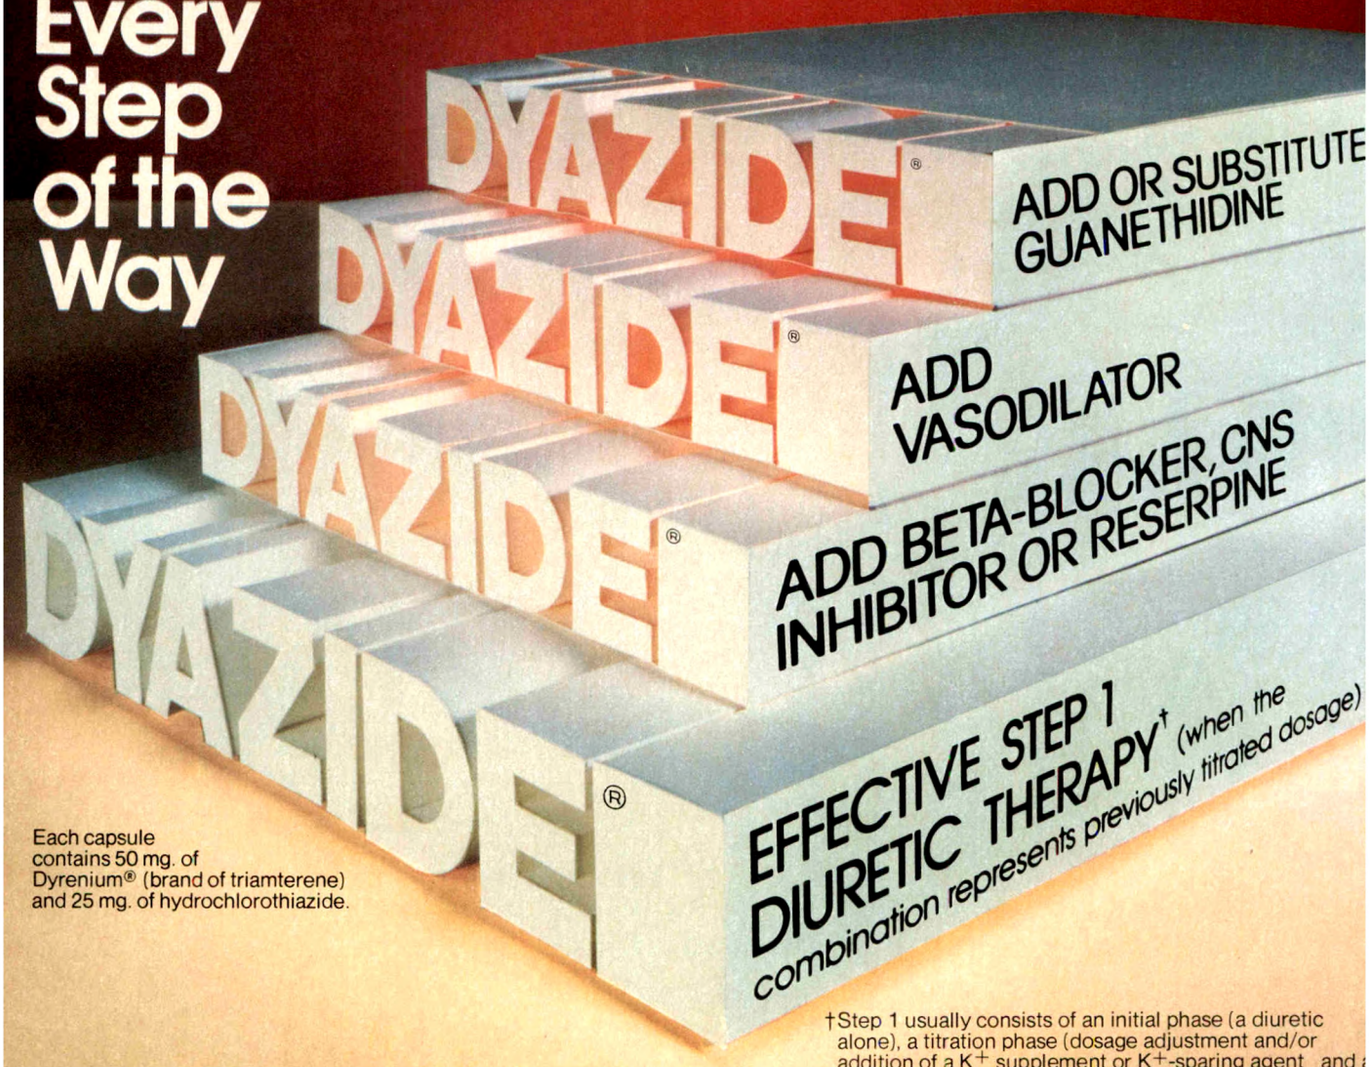
In Hypertension*...When You Need to Conserve K^+

Every Step of the Way



Each capsule contains 50 mg. of Dyrenium® (brand of triamterene) and 25 mg. of hydrochlorothiazide.

†Step 1 usually consists of an initial phase (a diuretic alone), a titration phase (dosage adjustment and/or addition of a K^+ supplement or K^+-sparing agent and a maintenance phase (a diuretic alone or in combination with a K^+ supplement or K^+-sparing agent).

Serum K^+ and BUN should be checked periodically (see Warnings).

Before prescribing, see complete prescribing information in SK&F Co. literature or *PDR*. A brief summary follows:

* **WARNING**
This drug is not indicated for initial therapy of edema or hypertension. Edema or hypertension requires therapy titrated to the individual. If this combination represents the dosage so determined, its use may be more convenient in patient management. Treatment of hypertension and edema is not static, but must be reevaluated as conditions in each patient warrant.

Contraindications: Further use in anuria, progressive renal or hepatic dysfunction, hyperkalemia. Pre-existing elevated serum potassium. Hypersensitivity to either component or other sulfonamide-derived drugs.

Warnings: Do not use potassium supplements, dietary or otherwise, unless hypokalemia develops or dietary intake of potassium is markedly impaired. If supplementary potassium is needed, potassium tablets should not be used. Hyperkalemia can occur, and has been associated with cardiac irregularities. It is more likely in the severely ill, with urine volume less than one liter/day, the elderly and diabetics with suspected or confirmed renal insufficiency. Periodically, serum K^+ levels should be determined. If hyperkalemia develops, substitute a thiazide alone, restrict K^+ intake. **Associated widened QRS complex or arrhythmia requires prompt additional therapy.** Thiazides cross the placental barrier and appear in cord blood. Use in pregnancy requires weighing anticipated benefits against possible hazards, including fetal or neonatal jaundice, thrombocytopenia, other adverse reactions seen in adults. Thiazides appear and triamterene may appear in breast milk. If their use is essential, the patient should stop nursing. Adequate information on use in children is not available. Sensitivity reactions may occur in patients with or without a history of allergy or bronchial asthma. Possible exacerbation or activation of systemic lupus erythematosus has been reported with thiazide diuretics.

Precautions: Do periodic serum electrolyte determinations (particularly important in patients vomiting excessively or receiving parenteral fluids). Periodic BUN and serum creatinine determinations should be made, especially in the elderly, diabetics or those with suspected or confirmed renal insufficiency. Watch for signs of impending coma in severe liver disease. If spironolactone is used concomitantly, determine serum K^+ frequently; both can cause K^+ retention and elevated serum K^+. Two deaths have been reported with such concomitant therapy (in one, recommended dosage was exceeded, in the other serum electrolytes were not properly monitored). Observe regularly for possible blood dyscrasias, liver damage, other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving triamterene, and leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with thiazides. Triamterene is a weak folic acid antagonist. Do periodic blood studies in cirrhotics with splenomegaly. Antihypertensive effect may be enhanced in postsympathectomy patients. Use cautiously in surgical patients. The following may occur: transient elevated BUN or creatinine or both, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), hyperuricemia and gout, digitalis intoxication (in hypokalemia), decreasing alkali reserve with possible metabolic acidosis. 'Dyazide' interferes with fluorescent measurement of quinidine. Hypokalemia, although uncommon, has been reported. Corrective measures should be instituted cautiously and serum potassium levels determined. Discontinue corrective measures and 'Dyazide' should laboratory values reveal elevated serum potassium. Chloride deficit may occur as well as dilutional hyponatremia. Serum PBI levels may decrease without signs of thyroid disturbance. Calcium excretion is decreased by thiazides. 'Dyazide' should be withdrawn before conducting tests for parathyroid function.

Diuretics reduce renal clearance of lithium and increase the risk of lithium toxicity.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis; rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting, diarrhea, constipation, other gastrointestinal disturbances. Necrotizing vasculitis, paresthesias, icterus, pancreatitis, xanthopsia and, rarely, allergic pneumonitis have occurred with thiazides alone. Triamterene has been found in renal stones in association with other usual calculus components.

Supplied: Bottles of 1000 capsules; Single Unit Packages (unit-dose) of 100 (intended for institutional use only); in Patient-Pak™ unit-of-use bottles of 100.

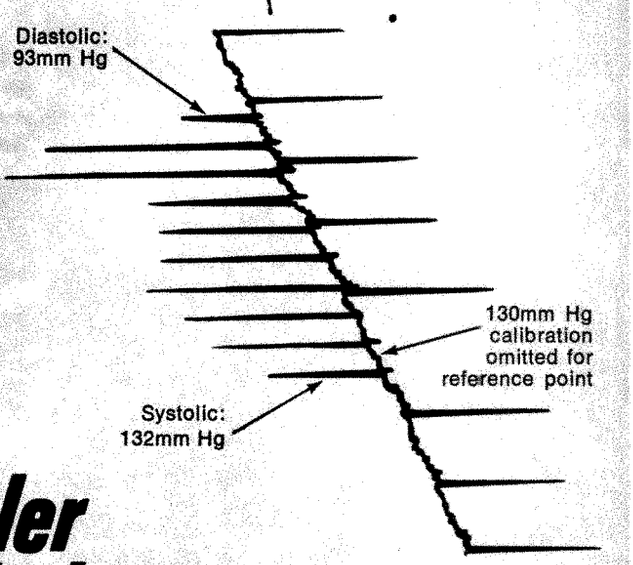
All Remler Blood Pressure Equipment displays calibrations which are directly traceable to the NATIONAL BUREAU OF STANDARDS.

One of as many as 60* blood pressure readings taken throughout the day by an ambulatory patient.



Remler Ambulatory Blood Pressure Recorder...

Light, compact one-piece unit weighs only 25 ounces

The Remler patented Ambulatory Blood Pressure Recorder has been in use for more than ten years by leading physicians and research institutions throughout the world. It is a proven, easy-to-use system and the only available blood pressure device that completely prints out calibrated blood pressure measurements showing all Korotkoff sounds.

This Model M-2000 records blood pressures during the wearer's working or leisure day. Wearing this unobtrusive, light-weight device on a belt, your patient can easily record blood pressure data onto the micro-cassette as many as sixty times daily. This method *totally eliminates bias,* and the pressor effect of an observer's presence.

A further advantage of the Remler system is the substantial savings in cost over manual methods for obtaining a multiple series of blood pressure measurements.

Remler Company AJC-2/81

Since 1918 • Precision in Electronics
280 Visitacion Mall • Brisbane, California 94005 USA • (415) 468-3437

Please send me complete details on the Remler Ambulatory Blood Pressure Recording System

SUBJECT INDEX: ABSTRACTS

Adenosine
Additional evidence for adenosine mediation of A-V conduction disturbances in canine myocardium, 429

Adenosine triphosphatase
Effect of prolonged prazosin treatment on the hemodynamics and cardiac electrolytes and Na^+-K^+ATPase in dogs with chronic aortic stenosis, 426

Adriamycin
Ultrasonic detection of the altered acoustic properties of myocardium characteristic of adriamycin-induced cardiomyopathy, 471

Age
Coronary angiography and coronary artery bypass surgery in elderly patients, 494

Alcalosis
Clinical use of alcalosis as a provocative test of coronary spasm, 450

Alcohol
Effect of alcohol on left ventricular relaxation in coronary artery disease: echocardiographic assessment by computer assisted analysis of left ventricular wall velocity, 462

Alpha adrenergic blockade
Labetalol therapy in angina pectoris and systemic hypertension: effects of combined alpha-beta adrenergic blockade, 430
Reduction of myocardial ischemia by balanced alpha and beta blockade with labetalol, 430

Amiodarone
Role of serum T4 and reversed T3 in monitoring antiarrhythmic efficacy and toxicity of amiodarone in resistant arrhythmias, 482

Amrinone
Acute effects of amrinone (5-amino-3,4′-bipyridin-6(1H)-one) on systemic blood flow distribution, 491
Intravenous and oral amrinone therapy in refractory heart failure: hemodynamics, exercise results, and side effects, 491
Long term effect of oral amrinone in heart failure: improvement in exercise performance despite declining left ventricular pump function, 428

Amyloid
Prealbumin is a component of senile cardiac amyloid, 421

Amyloidosis
Electrocardiographic "low voltage, anterior wall myocardial infarct pattern, arrhythmias and absence on left ventricular hypertrophy"—The characteristic electrocardiogram of amyloid heart disease from analysis of 40 necropsy patients, 465

Anesthetic agents
Site of action of local anesthetics on heart fibers, 475

Aneurysms
Murine Coxsackievirus B4 cardiomyopathy; myocardial infarction and ventricular aneurysms, 421

Angina pectoris
Benefits of added nifedipine in unstable angina persisting despite beta blockade and isosorbide dinitrate, 399
Comparison of verapamil and nifedipine in patients with Prinzmetal's variant angina pectoris, 398
Double-blind, randomized, placebo-controlled comparison of propranolol and verapamil in patients with stable, exertional angina pectoris, 463
Effects of verapamil and nifedipine on left ventricular function in patients with Prinzmetal's variant angina, 394
Exacerbation of ischemia in vasotonic angina pectoris by propranolol, 463
Labetalol therapy in angina pectoris and systemic hypertension: effects of combined alpha-beta adrenergic blockade, 430
Placebo response in vasotonic angina-a critical factor in drug trial design, 398
Prognosis of variant angina patients treated with calcium antagonist drugs, 463
Unstable angina: effect of medical versus surgical therapy on survival and myocardial infarction, 486
Verapamil in the treatment of Prinzmetal's variant angina: a long-term, double-blind, randomized trial, 399

Angiocardiography
Angiographic dye relaxes canine coronary artery by a non-osmotic mechanism, 407
Automated method for left ventricular volume measurement from the cineventriculography with minimal doses of contrast medium, 394
Coronary angiography and coronary artery bypass surgery in elderly patients, 494
Correlation of cineangiography and blood pool scan for measurement of left ventricular volume in human cadaver hearts, 455
Detection of left ventricular thrombi by radionuclide angiography, 474
Echocardiographic and angiocardiographic features before and after the Jatene procedure (arterial switch) for transposition of the great arteries, 431
Experimental coronary artery spasm in intact dog: angiographic characterization, recording of flow, and response to dihydropyridines, 449
Idiopathic prolapse of the mitral valve: follow-up study of 136 patients studied by angiography, 426
Potential role of intravenous angiography in management of cardiac surgery patients, 400
Radionuclide angiocardiographic assessment of patients following repair of transposition of the great arteries, 473

Angiocardiography, radionuclide
Accuracy of radionuclide angiocardiography in the diagnosis of coronary artery disease—a prospective study, 444
Gated radionuclide angiography during upright exercise in patients with programmable pacemakers, 435
Radionuclide angiography and endomyocardial biopsy in the assessment of doxorubicin cardiotoxicity, 401

Angioplasty, percutaneous transluminal coronary
Acute and chronic effects of transluminal angioplasty in experimental atherosclerosis, 395
Beneficial results from transluminal coronary angioplasty assessed by quantitative cross-sectional coronary arteriography, 396
Clinical experience with a new catheter system for percutaneous transluminal coronary angioplasty, 395
Evaluation of transluminal coronary angioplasty in left main coronary artery stenosis, 396
National heart, lung and blood institute registry report of complications of percutaneous transluminal coronary angioplasty, 396

Antiarrhythmic therapy
Benefits and risks of combined burst pacing and drug therapy of recurrent ventricular tachycardia, 476
Chronic intravenous infusion of antiarrhythmic drugs using a totally implanted drug delivery system, 437
Reproducibility of electrophysiologic responses to programmed ventricular stimulation during serial drug testing in patients with recurrent ventricular tachycardia, 449

Antihypertensive agents
Effect of antihypertensive medications on physical work capacity, 415

Antiplatelet therapy
Improved graft patency with antiplatelet drugs in patients treated for one year following coronary bypass surgery, 494

Aorta, thoracic
Computed tomography. A useful technique for follow-up of both medically and surgically treated patients with thoracic aortic dissection, 451

Aortic arches
Reciprocal development of 4th and 6th aortic arches in pulmonary atresia with ventricular septal defect, 447

Aortic insufficiency
Effect of acute aortic insufficiency on the dynamics of mitral valve motion and instantaneous trans-mitral flow: hemodynamic mechanism for the austin flint murmur, 426

Evaluation of left ventricular function at rest and during exercise by transesophageal echocardiography in aortic insufficiency, 412

Aortic regurgitation
- Efficacy of afterload reduction in aortic regurgitation: assessment by two-dimensional echo, 413
- Has echocardiography any place in determining the timing of operation in aortic regurgitation? 425
- Is isovolumic relaxation impaired in secondary hypertrophy? 395
- Left ventricular ejection rate during the first third of systole in patients with aortic insufficiency, 410
- Noninflammatory aortic root disease: an important cause of aortic regurgitation. Echocardiographic and histopathologic correlation, 425
- Noninvasive determination of the endsystolic pressure volume relation in patients with aortic regurgitation, 427
- Quantitation of aortic regurgitation with two-dimensional Doppler echocardiography, 412
- Value of measuring anaerobic threshold during radionuclide exercise testing in aortic regurgitation, 473

Aortic root
- Noninflammatory aortic root disease: an important cause of aortic regurgitation. Echocardiographic and histopathologic correlation, 425

Aortic stenosis
- Effect of prolonged prazosin treatment on the hemodynamics and cardiac electrolytes and Na^+-K^+ATPase in dogs with chronic aortic stenosis, 426
- Is isovolumic relaxation impaired in secondary hypertrophy? 395

Aortic valve disease
- Correlations of fibrosis in left ventricular endomyocardial biopsies from patients with aortic valve disease, 421
- Platelet reactivity in patients with aortic valve disease, 499

Arrhythmias
- Arrhythmogenicity of encainide. The role of QT interval, 498
- Cardiac rhythm, arterial pressure, and urinary catecholamines in hypertension with and without left ventricular hypertrophy, 480
- Effect of interruption of collateral blood flow on conduction delay and arrhythmias during acute myocardial ischemia, 391
- Effects of coupling intervals on contraction patterns of premature beats derived by computer assisted two-dimensional echocardiography, 471
- Effects of $[K+]_0$ on membrane potential, delayed afterdepolarizations and triggered activity in atrial fibers of the canine coronary sinus, 405
- Endomyocardial biopsy in patients with life-threatening ventricular dysrhythmia, 499
- Estimation of ventricular repolarization duration and disparity from distributions of QRST area, 489
- Meobentine sulfate: antiarrhythmic efficacy and mechanism of action in a chronic canine model of myocardial infarction susceptible to ventricular tachyarrhythmias, 392
- Non-computerized on-line epicardial and intramural mapping of ventricular arrhythmias, 488
- Oral flecainide acetate for elimination of ventricular arrhythmias in man, 482
- Prevention of postoperative supraventricular tachyarrhythmia in coronary bypass patients, with low-dose propranolol, 431
- Programmed premature stimulation as a guide to antiarrhythmic therapy for malignant ventricular arrhythmia in the absence of ambient ectopy, 497
- Role of serum T4 and reversed T3 in monitoring antiarrhythmic efficacy and toxicity of amiodarone in resistant arrhythmias, 482
- Use of fetal echocardiography in the diagnosis and management of antenatal arrhythmias, 457

Arteriography
- Angiographic dye relaxes canine coronary artery by a non-osmotic mechanism, 407
- Beneficial results from transluminal coronary angioplasty assessed by quantitative cross-sectional coronary arteriography, 396
- Thallium-201 myocardial perfusion imaging in women: correlation with coronary arteriography, 422
- Therapeutic and economic impact of normal coronary arteriograms in patients with severe chest pain, 464

Aspirin
- Failure of aspirin to prevent incorporation of indium labelled platelets into cardiac thrombi in man, 455

Atenolol
- Pain relief in acute myocardial infarction by intravenous atenolol, 489

Atrial fibrillation
- Atrial excitability and conduction in patients prone to atrial fibrillation, 496

Atrioventricular canal
- Complete atrioventricular canal associated with tetralogy of Fallot, 467
- Partial atrioventricular canal defect in adults, 466

Atrioventricular node
- Autonomic modulation of A-V nodal conduction in conscious dogs, 428
- Differences in responsiveness of SA and AV node to vagal stimulation, 429
- Membrane current systems in the rabbit atrioventricular node. The first voltage clamp study, 429
- Nodal function in 30 patients with atrioventricular nodal 1/1 conduction above 200/mn, 433

Automaticity
- Stabilizing effect of insulin on automaticity in partially depolarized cardiac Purkinje fibers, 475

Bed rest
- Effects of bedrest deconditioning on exercise ventricular function in middle-aged men, 477

Beta adrenergic blockade
- Benefits of added nifedipine in unstable angina persisting despite beta blockade and isosorbide dinitrate, 399
- Effect of beta blockade therapy on hypertensive cardiac hypertrophy, 469
- Labetalol therapy in angina pectoris and systemic hypertension: effects of combined alpha-beta adrenergic blockade, 430
- Reduction in infarct size and morbidity by early intravenous betablockade, 490
- Reduction of myocardial ischemia by balanced alpha and beta blockade with labetalol, 430

Beta adrenoceptor agonists
- Hemodynamic effects of a new $beta_1$-agonist (prenalterol) in patients with congestive heart failure, 428
- Potential value of oral β_2 adrenoceptor agonists in left ventricular failure, 427

Betathromboglobulin
- Platelet survival time and betathromboglobulin in cardiac valve replacement, 498

Biopsy
- Endomyocardial biopsy in patients with life-threatening ventricular dysrhythmia, 499
- Myocardial biopsy in patients with ventricular tachycardia, 499
- Radionuclide angiography and endomyocardial biopsy in the assessment of doxorubicin cardiotoxicity, 401
- Usefulness of septal endomyocardial biopsy for early diagnosis of chagasic cardiomyopathy, 401
- Use of transvenous myocardial biopsy to diagnose and accurately evaluate diseases of the myocardium, 499

Blood flow
- Acute effects of amrinone (5-amino-3,4′-bipyridin-6(1H)-one) on systemic blood flow distribution, 491
- Effect of dopamine and dobutamine on regional blood flow, myocardial oxygen consumption and high energy phosphate compounds during cardiopulmonary bypass, 416
- Flow-independent characteristics of externally detectable cardiac kinetics of ^{11}C-palmitate, 414
- Influence of nifedipine on myocardial blood flow in the ischemic and lateral border zones, 442
- Influence of nifedipine on myocardial blood flow during three grades of coronary occlusion, 472
- Myocardial blood flow at rest and during exercise in dogs with left ventricular hypertrophy, 446
- Non-invasive evaluation of cerebral blood flow during ventricular and A-V sequential pacing, 435
- Quantitative Doppler flow estimators: improved characterization and separation of normal from abnormal flow, 461
- Relationship of thallium-201 perfusion images to regional myocardial blood flow in man, 484

Blood flow, coronary
- Doppler sones quantitation of coronary blood flow in man during dipyridamole coronary vasodilatation, 407
- Effects of prostacyclin (PGI_2) on coronary blood flow in open-chest dogs after different routes of administration, 472
- Limited influence of capacitive effects on coronary pressure-flow relations and zero-flow pressures determined during single long diastoles, 473
- Quantification of myocardial function

during transient changes in regional coronary blood flow, 445

Blood platelets
Antiplatelet effects of verapamil in man, 399
Consistent platelet activation associated with early recurrent myocardial infarction, 456
Effect of ibuprofen on platelet deposition in gore-tex and autologous vein grafts, 455
Effects of nitroglycerin on intracoronary platelet aggregation and ventricular vulnerability during partial coronary stenosis, 489
Failure of aspirin to prevent incorporation of indium labelled platelets into cardiac thrombi in man, 455
Platelet activity in coronary disease, relationship to smoking and hyperlipidemia, 456
Platelet reactivity in patients with aortic valve disease, 499
Platelet survival time and betathromboglobulin in cardiac valve replacement, 498
Platelet thrombus formation is stenosed canine coronary arteries and their inhibition with ibuprofen, 456
Red cell involvement in platelet thrombi formed in stenosed canine coronary arteries, 456

Blood pressure
Abnormal blood pressure response during an exercise test, 423
Blood pressure related echocardiographic changes in adolescents and young adults, 420

Bretylium tosylate
Lack of effectiveness of bretylium in paroxysmal sustained ventricular tachycardia, 438

Bundle branch block
Effect of rate-dependent left bundle branch block on left ventricular ejection fraction and regional wall motion, 415

Calcium antagonists
Calcium antagonists: their effectiveness in decreasing the occurence of ventricular fibrillation and reducing infarct size after a coronary artery occlusion, 443
Prognosis of variant angina patients treated with calcium antagonist drugs, 463
Protection against ventricular fibrillation by calcium antagonists, 438

Cardiac catheterization
20 Month experience in outpatient cardiac catheterization, 451

Cardiac conduction
Analysis of antegrade and retrograde fast pathway properties in dual pathway patients, 434
Autonomic modulation of A-V nodal conduction in conscious dogs, 428
Closed chest permanent atrioventricular block in dogs: technique and anatomic changes, 428
Contrasting effects of procainamide and verapamil on intraventricular conduction and reentry, 449
Effect of isoproterenol on "residual fast channel-dependent slow conduction" produced in guinea pig ventricular muscle, 475
Effect of prostacyclin on ventricular arrhythmias and intracardiac conduction in myocardial ischemia, 437
Initiation of atrio-ventricular nodal re-entrant tachycardia in patients with discontinuous antegrade conduction curves. Importance of a discontinuous retrograde conduction curve, 434
New method of recording transmembrane action potential from atria of in situ heart, 404
Nodal function in 30 patients with atrioventricular nodal 1/1 conduction above 200/mn, 433
P synchronous pacing: a new orthogonal approach to P-wave sensing, 434

Cardiac conduction system
Multiple atrioventricular nodal pathways—a new electrophysiological phenomenon in children, 440

Cardiac output
Direct measurement of cardiac output by gated equilibrium blood pool scintigraphy, 454
Mechanism of low output in experimental right ventricular infarction, 437
Quantitation of left ventricular output in patients with and without left-sided valvular regurgitation using equilibrium radionuclide ventriculography, 454

Cardiac transplantation
Sinus node function after cardiac transplantation, 496

Cardiomyopathy
Abnormal mitral annular contraction in cardiomyopathies and correlation with left ventricular function, 409
Cardiac effects of plasma from patients with Graves' disease, 402
Clinical utility of plasma verapamil levels in patients with hypertrophic cardiomyopathy, 407
Differentiation of constrictive pericarditis and restrictive cardiomyopathy by echocardiography, 462
Efficacy of 24 hour ambulatory ECG monitoring as a predictor of sudden death in hypertrophic cardiomyopathy, 480
Hypertrophic cardiomyopathy: measurement of cation uptake, 409
Limitations of histological morphometric analysis in predicting drug preservation of contractility in cardiomyopathy, 460
Long-term effects of verapamil on left ventricular diastolic filling in patients with hypertrophic cardiomyopathy, 409
Murine Coxsackievirus B4 cardiomyopathy; myocardial infarction and ventricular aneurysms, 421
Myocardial biopsy in patients with ventricular tachycardia, 499
Protective effects of verapamil and hydralazine on the cardiomyopathy of the Syrian hamster, 460
Reversal of diabetic cardiomyopathy by insulin treatment, 460
Reversibility of diabetic cardiomyopathy with insulin in rats, 414
Right ventricular cardiomyopathy presenting with recurrent ventricular tachycardia, 402
Ultrasonic detection of the altered acoustic properties of myocardium characteristic of adriamycin-induced cardiomyopathy, 471
Usefulness of septal endomyocardial biopsy for early diagnosis of chagasic cardiomyopathy, 401

Cardioplegia
Comparative effects of intermittent ischemic arrest and potassium cardioplegia on diastolic ventricular compliance in patients, 417
Electrophysiology of the canine sinus node during cardiopulmonary bypass: technique for localization and response to cold cardioplegia, 405
Enhanced myocardial preservation in animals and man with nifedipine and cardioplegia, 416

Cardiopulmonary bypass
Effect of dopamine and dobutamine on regional blood flow, myocardial oxygen consumption and high energy phosphate compounds during cardiopulmonary bypass, 416
Electrophysiology of the canine sinus node during cardiopulmonary bypass: technique for localization and response to cold cardioplegia, 405
Preservation of interventricular septal function in patients having coronary artery bypass grafts without cardiopulmonary bypass, 394

Cardiopulmonary resuscitation
Two dimensional echocardiography of the heart during cardiopulmonary resuscitation in man, 398

Catecholamines
Inotropic and chronotropic effects of insulin in the conscious dog: contribution of catecholamines and hypoglycemia, 460

Catheter
Clinical experience with a new catheter system for percutaneous transluminal coronary angioplasty, 395
Diagnosis of pacing catheter perforation by real time two-dimensional echocardiography, 462

Chagas' disease
Usefulness of septal endomyocardial biopsy for early diagnosis of chagasic cardiomyopathy, 401

Chest pain
Exercise testing of women with chest pain with and without thallium tomography, 422
Therapeutic and economic impact of normal coronary arteriograms in patients with severe chest pain, 464

Cholesterol
Accelerated coronary atherosclerosis following cardiac transplantation: significance of hypercholesterolemia, 452
Familial hypercholesterolemic families' response to food products containing LBG, 487
High density lipoprotein and total cholesterol as predictors of 7-year mortality from coronary heart disease, cancer and all causes, 486
Relationship between plasma testosterone and lipoprotein cholesterol, 420

Cigarette smoking
Cigarette smoking and non-fatal myocardial infarction in women, 420

Cold pressor test
Cold pressor echocardiography, 453
Cold pressor thallium 201 myocardial scintigraphy in detection of coronary artery disease: an alternative to exercise scintigraphy, 444
Effects of cold-pressor test on regional coronary hemodynamic and angiographic responses, 450
Conduction system
Morphologic basis for electrocardiographic evidence of conduction system involvement in Duchenne's Muscular Dystrophy (DMD), 402
Congenital heart defects
Clinical and electrophysiologic prediction of need for pacemaker insertion in children with congenital complete atrioventricular block, 439
Echocardiographic diagnosis of absent pulmonary valve syndrome in the neonate, 479
Haemodynamic effects of haematocrit reduction in patients with cyanotic congenital heart disease and secondary polycythaemia, 451
Operability of adults with left to right shunts, cyanosis, and pulmonary vascular obstruction, 424
Partial atrioventricular canal defect in adults, 466
Prospective diagnosis of conotruncal malformations in infants using subxiphoid two-dimensional echocardiography, 457
Two-dimensional (2D) echocardiographic imaging of atrioventricular (AV) valves, septal structures, and rudimentary outflow chambers (RC) in patients with univentricular hearts (UH), 479
Congestive heart failure
Acute and follow-up studies with pirbuterol in heart failure, 492
Assessment of prazosin alpha receptor blockade with phentolamine: acute, subacute and late hemodynamic evaluation during sustained beneficial vasodilator therapy in congestive heart failure, 390
Comparative cardiocirculatory actions of new selective beta-1 agonist prenalterol vs dobutamine: demonstration of equivalent beneficial effects on cardiac pump performance in congestive heart failure, 492
Enhanced oxyhemoglobin dissociation contributes to unloading oxygen at rest and during exercise in severe chronic heart failure patients, 468
Hemodynamic and metabolic effects of terbutaline in patients with severe heart failure, 491
Hemodynamic effects of a new beta$_1$-agonist (prenalterol) in patients with congestive heart failure, 428
Intravenous and oral amrinone therapy in refractory heart failure: hemodynamics, exercise results, and side effects, 491
Long term effect of oral amrinone in heart failure: improvement in exercise performance despite declining left ventricular pump function, 428
Maximal improvement in ventricular performance during rest and exercise in chronic severe cardiac failure by combined inotropic and vasodilator therapy compared to either modality alone, 390
Mechanism of transient prazosin hemodynamic "tachyphylaxis" in heart failure: acute, subacute and late serial evaluation of alpha receptor responses with phenylephrine by cardiac catheterization during prolonged oral prazosin therapy, 389
Sustained beneficial effect of nifedipine in chronic refractory heart failure, 407
Sympathetic response to exercise in patients with congestive heart failure, 395
Contrast medium
Transmission of echocardiographic contrast through the lungs, 470
Transmission of echocardiographic contrast through the lungs. II: human studies, 470
Coronary arteries
Adrenergic tone in the canine coronary circulation, 472
Beta adrenergic control of large coronary vessels in conscious dogs, 472
Cross-sectional ultrasonic imaging of the coronary arteries (CA's) in open chested humans; the evaluation of coronary atherosclerotic lesions (ACL) at surgery, 403
How does systolic coronary artery compression cause myocardial ischemia in dogs? 473
Therapeutic and economic impact of normal coronary arteriograms in patients with severe chest pain, 464
Coronary arteries, collateral
Effect of interruption of collateral blood flow on conduction delay and arrhythmias during acute myocardial ischemia, 391
Coronary arteries, left main
Asymptomatic left main coronary artery disease, 408
Prognostic significance of left main equivalent stenosis, 408
Total occlusion of the left main coronary artery: the CASS experience, 408
Coronary artery disease
A-B coronary-prone behavior pattern and cardiovascular risk factor variables in children and adolescents: the Bogalusa heart study, 419
Accelerated coronary atherosclerosis following cardiac transplantation: significance of hypercholesterolemia, 452
Accuracy of radionuclide angiocardiography in the diagnosis of coronary artery disease—a prospective study, 444
Acute and chronic effects of transluminal angioplasty in experimental atherosclerosis, 395
Angiographic dye relaxes canine coronary artery by a non-osmotic mechanism, 407
Asymptomatic left main coronary artery disease, 408
Beneficial effects of diltiazem on exercise performance in patients with coronary artery disease and angina pectoris, 464
Beneficial results from transluminal coronary angioplasty assessed by quantitative cross-sectional coronary arteriography, 396
Brief repeat periods of ischemia have a cumulative effect and may cause myocardial necrosis, 445
Changes in late coronary artery bypass grafts: the variability of their intimal atherosclerosis, 401
Changes in left ventricular volumes during upright exercise in patients with coronary artery disease, 468
Clinical experience with a new catheter system for percutaneous transluminal coronary angioplasty, 395
Clinical utility of cold pressor radionuclide ventriculography in coronary artery disease, 444
Cohort analysis of secular change in mortality in patients with CAD undergoing surgical intervention, 487
Cold pressor thallium 201 myocardial scintigraphy in detection of coronary artery disease: an alternative to exercise scintigraphy, 444
Coronary bypass vs medicine: problems and guidelines in assessing mortality differences, 400
Current risk surrounding coronary bypass surgery, 400
Demonstation of exercise-induced ischemia without angina in patients who recover from out-of-hospital ventricular fibrillation, 445
Differing effects of verapamil relative to varying levels of myocardial performance in patients with coronary artery disease, 406
Doppler sones quantitation of coronary blood flow in man during dipyridamole coronary vasodilatation, 407
Effect of alcohol on left ventricular relaxation in coronary artery disease: echocardiographic assessment by computer assisted analysis of left ventricular wall velocity, 462
Effect of medical and surgical therapy on prognosis in patients with isolated left anterior descending coronary artery disease, 486
Effects of cold-pressor test on regional coronary hemodynamic and angiographic responses, 450
Effects of moderate and high dose propranolol on ventricular function in patients with coronary artery disease, 430
Evaluation of transluminal coronary angioplasty in left main coronary artery stenosis, 396
Haemodynamic monitoring in painless myocardial ischaemia, 446
High density lipoprotein and total cholesterol as predictors of 7-year mortality from coronary heart disease, cancer and all causes, 486
Inhibition of leukocyte migration by mononuclear cell supernatants from patients with ischemic heart disease, 452
Inotropic contractile reserve: a useful predictor of increased five year postoperative survival and improved left ventricular function in patients with coronary artery disease and a depressed ejection fraction, 495
Left ventricular function before and after successful catheter dilatation of critical coronary stenoses, 396
Left ventricular response to exercise

after anterior myocardial infarction: differences between patients with single and multivessel coronary artery disease, 408
Lysis of coronary artery thrombosis with intracoronary streptokinase in acute myocardial infarction, 493
National heart, lung and blood institute registry report of complications of percutaneous transluminal coronary angioplasty, 396
Non transmural (subendocardial) myocardial infarction in man: the prevalence of total coronary occlusion, 459
Oral verapamil vs propranolol in coronary artery disease: evaluation of left ventricular function by exercise radionuclide ventriculography, 463
Platelet activity in coronary disease, relationship to smoking and hyperlipidemia, 456
Platelet thrombus formation is stenosed canine coronary arteries and their inhibition with ibuprofen, 456
Positive labeling of ischemic myocardium: a new approach in patients with coronary disease, 481
Potential role of intravenous angiography in management of cardiac surgery patients, 400
Precordial electrocardiographic mapping in the identification of patients with left main stem disease, 423
Predicting the extent and location of coronary disease two-weeks post-myocardial infarction by thallium-201 scintigraphy, 484
Prognosis of patients with coronary artery disease by exercise testing, 415
Prognostic significance of left main equivalent stenosis, 408
Prognostic value of ventricular arrhythmias, 397
Quantification of myocardial function during transient changes in regional coronary blood flow, 445
Quantification of regional myocardial blood content in normal, ischemic and reperfused myocardium, 445
Quantitative analysis of stress distribution and washout of T1-201 myocardial scintigrams: superiority over visual assessment for evaluation of coronary artery disease, 443
Red cell involvement in platelet thrombi formed in stenosed canine coronary arteries, 456
Regional ejection fraction image (REFI)—an accurate method for the detection of coronary heart disease, 444
Relation of exercise electrocardiographic ST changes to physiological measurements in men at high risk of future coronary death, 420
Sensitivity of exercise induced changes in apex of T to end of T and QT intervals for detecting coronary disease, 423
Serial right ventricular thallium imaging following dipyridamole and relationship to right coronary artery disease, 484
Systemic lupus erythematosus and ischemic coronary artery disease, 446
Total occlusion of the left main coronary artery: the CASS experience, 408
Transluminal recanalization during evolving myocardial infarct in man, 492
Two-dimensional echocardiographic assessment of wall thinning and its relation to perfusion during graded coronary stenosis, 403
Vascular determinants of early recurrent myocardial infarction, 418

Coronary occlusion
Calcium antagonists: their effectiveness in decreasing the occurence of ventricular fibrillation and reducing infarct size after a coronary artery occlusion, 443
Daily exercise augments antegrade flow following partial coronary occlusion, 467
Influence of nifedipine on myocardial blood flow during three grades of coronary occlusion, 472

Coronary perfusion
Nitroprusside improves coronary perfusion in regional ischemia in conscious dogs with normal and high left ventricular diastolic pressure, 442
Quantitation of myocardial perfusion in man using oxygen-15 and positron tomography, 481

Coronary reperfusion
Divergent effects of inotropic stimulation on the mechanical function of the ischemic and the severely depressed reperfused myocardium, 442
Does nifedipine protect against reperfusion damage? 461
Quantification of regional myocardial blood content in normal, ischemic and reperfused myocardium, 445
Salvage of jeopardized myocardium by non-surgical reperfusion (NSR) in man, 493
Time course of vulnerability to reperfusion-induced ventricular fibrillation, 461

Coronary spasm
Clinical use of alcalosis as a provocative test of coronary spasm, 450
Coronary artery spasm: an isolated phenomenon or one manifestation of a more diffuse vascular hyperreactivity? 450
Coronary vasospasm provoked by the hyperventilation test, 450
Experimental coronary artery spasm in intact dog: angiographic characterization, recording of flow, and response to dihydropyridines, 449
Frequency of provoked coronary arterial spasm in patients with recent transmural myocardial infarction, 490
How useful is the electrocardiogram as an indicator of coronary artery spasm? 449
Reversible segmental contraction abnormalities during exercise induced coronary artery spasm and their effect on global left ventricular function, 451

Costs
Fifteen year comparative study of cardiac pacing costs, 392

Counterpulsation, intraaortic balloon
Comparison of techniques for intraaortic balloon insertion, 417

Coxsackievirus
Murine Coxsackievirus B4 cardiomyopathy; myocardial infarction and ventricular aneurysms, 421

C-^{11} palmitate
Flow-independent characteristics of externally detectable cardiac kinetics of ^{11}C-palmitate, 414
Kinetics of C-11 labeled palmitate in ischemic myocardium, 414

Cyanosis
Haemodynamic effects of haematocrit reduction in patients with cyanotic congenital heart disease and secondary polycythaemia, 451

Cycle length
Comparative effects of cycle length on ventricular refractoriness of normal and chronically infarcted myocardium, 391

Death, sudden
Efficacy of 24 hour ambulatory ECG monitoring as a predictor of sudden death in hypertrophic cardiomyopathy, 480
Improved survival in sudden death/ventricular tachycardia patients with therapeutic antiarrhythmic drug levels, 438
Predictive value of programmed electrical stimulation in patients with sudden death or recurrent ventricular tachycardia, 397
Prolonged QT interval and autonomic imbalance: a clue for the prevention of sudden death in mitral valve prolapse, 480

Defibrillation
Low energy versus high energy defibrillation in the treatment of out-of-hospital ventricular fibrillation. A preliminary report, 398

Defibrillator, automatic
Electrophysiologic studies before and after implantation of the automatic defibrillator, 397

Diabetes mellitus
Reversal of diabetic cardiomyopathy by insulin treatment, 460
Reversibility of diabetic cardiomyopathy with insulin in rats, 414

Diazoxide
Comparative hemodynamic and clinical responses to isuprel, diazoxide and hydralazine in severe precapillary pulmonary hypertension, 422

Digitalis
Digitalis and exercise testing, a five year followup, 416

Digoxin
Clinical implications of serum digoxin concentrations, 486

Dihydropyridines
Experimental coronary artery spasm in intact dog: angiographic characterization, recording of flow, and response to dihydropyridines, 449

Diltiazem
Beneficial effects of diltiazem on exercise performance in patients with coronary artery disease and angina pectoris, 464
Protection of ischemic myocardium by diltiazem, 442

Dipole ranging
Determination of cardiac dipole locations during ventricular recovery in normal men, 465

Dipyridamole
Doppler sones quantitation of coronary blood flow in man during dipyridamole coronary vasodilatation, 407

Serial right ventricular thallium imaging following dipyridamole and relationship to right coronary artery disease, 484
Utility of serial thallium imaging following dipyridamole, 483

Disopyramide
Disopyramide phosphate in Wolff-Parkinson-White syndrome, 495

Dobutamine
Comparative cardiocirculatory actions of new selective beta-1 agonist prenalterol vs dobutamine: demonstration of equivalent beneficial effects on cardiac pump performance in congestive heart failure, 492
Effect of dopamine and dobutamine on regional blood flow, myocardial oxygen consumption and high energy phosphate compounds during cardiopulmonary bypass, 416

Dopamine
Divergent effects of inotropic stimulation on the mechanical function of the ischemic and the severely depressed reperfused myocardium, 442
Effect of dopamine and dobutamine on regional blood flow, myocardial oxygen consumption and high energy phosphate compounds during cardiopulmonary bypass, 416

Doppler ultrasound
Doppler sones quantitation of coronary blood flow in man during dipyridamole coronary vasodilatation, 407
Pulmonary valve atresia: diagnosis by pulse Doppler/two-dimensional echocardiography, 457
Quantitation of aortic regurgitation with two-dimensional Doppler echocardiography, 412
Quantitative Doppler flow estimators: improved characterization and separation of normal from abnormal flow, 461

Doxorubicin
Radionuclide angiography and endomyocardial biopsy in the assessment of doxorubicin cardiotoxicity, 401
Serial radionuclide assessment of doxorubicin cardiotoxicity in cancer patients with abnormal baseline resting left ventricular performance, 474

Duchenne's muscular dystrophy
Morphologic basis for electrocardiographic evidence of conduction system involvement in Duchenne's Muscular Dystrophy (DMD), 402

Ductus arteriosus
Morphologic features of the ductus arteriosus after PGE_1 administration for ductus dependent congenital heart disease, 447

Echocardiography
Abnormal mitral annular contraction in cardiomyopathies and correlation with left ventricular function, 409
Accuracy of M-mode echo measurements of the left ventricle, 453
Blood pressure related echocardiographic changes in adolescents and young adults, 420
Cold pressor echocardiography, 453
Cross-sectional echocardiography in the early detection of acute myocardial ischaemia and infarction, 404
Cross-sectional ultrasonic imaging of the coronary arteries (CA's) in open chested humans; the evaluation of coronary atherosclerotic lesions (ACL) at surgery, 403
Diagnosis of pacing catheter perforation by real time two-dimensional echocardiography, 462
Differentiation of constrictive pericarditis and restrictive cardiomyopathy by echocardiography, 462
Discrete intramural sonolucency: a new echocardiographic finding in acute myocardial infarction, 404
Dynamic intracavitary echocardiographic patterns associated with left ventricular mural thrombi: clinical and experimental observations, 471
Echocardiographic and angiocardiographic features before and after the Jatene procedure (arterial switch) for transposition of the great arteries, 431
Echocardiographic assessment of the St. Jude mitral prosthesis, 441
Echocardiographic changes during a 1 year exercise program in previously sedentary middle aged men, 477
Echocardiographic diagnosis of absent pulmonary valve syndrome in the neonate, 479
Echocardiographic evaluation of tricuspid annulus size and function in normal and in tricuspid regurgitation, 412
Echocardiographic evidence for early left ventricular hypertrophy in renal hypertensive dogs, 478
Effect of alcohol on left ventricular relaxation in coronary artery disease: echocardiographic assessment by computer assisted analysis of left ventricular wall velocity, 462
Effects of coupling intervals on contraction patterns of premature beats derived by computer assisted two-dimensional echocardiography, 471
Efficacy of afterload reduction in aortic regurgitation: assessment by two-dimensional echo, 413
Embolic potential of left ventricular thrombus (LVT) detected by two-dimensional echocardiography (2DE), 471
Evaluation of left ventricular function at rest and during exercise by transesophageal echocardiography in aortic insufficiency, 412
Evaluation of pacing function by real time two-dimensional echocardiography, 434
Evaluation of tricuspid atresia by two-dimensional echocardiography, 479
Has echocardiography any place in determining the timing of operation in aortic regurgitation? 425
Heterogeneity of segmental left ventricular wall thickening and excursion in two-dimensional echocardiograms of normal humans, 452
High frequency epicardial echo mapping of segmental myocardial performance at multiple sites on right and left ventricles, 403
Indium-III platelet scintigraphy and two dimensional echocardiography in the diagnosis of left ventricular thrombi, 474
Inferior vena caval ultrasonagraphy: its use in the assessment of right heart function, 453
Noninflammatory aortic root disease: an important cause of aortic regurgitation. Echocardiographic and histopathologic correlation, 425
Prospective diagnosis of conotruncal malformations in infants using subxiphoid two-dimensional echocardiography, 457
Pulmonary valve atresia: diagnosis by pulse Doppler/two-dimensional echocardiography, 457
Quantitation of aortic regurgitation with two-dimensional Doppler echocardiography, 412
Quantitative regional myocardial perfusion scanning with contract echocardiography, 403
Role of two-dimensional echocardiography in evaluation of patients with post myocardial infarction ventricular septal defect, 461
Simultaneous contrast two-dimensional echocardiography and contrast ventriculography: discrepancies in left ventricular volume, 453
Superiority of the American Society of Echocardiography criteria for measuring wall thickness by two-dimensional echocardiography, 462
Transmission of echocardiographic contrast through the lungs, 470
Transmission of echocardiographic contrast through the lungs. II: human studies, 470
Two-dimensional (2D) echocardiographic imaging of atrioventricular (AV) valves, septal structures, and rudimentary outflow chambers (RC) in patients with univentricular hearts (UH), 479
Two dimensional echocardiography of the heart during cardiopulmonary resuscitation in man, 398
Two-dimensional echocardiographic assessment of wall thinning and its relation to perfusion during graded coronary stenosis, 403
Two-dimensional echocardiographic identification of prolapse of individual scallops of posterior mitral leaflet, 412
Two dimensional echocardiographic evaluation of branch pulmonary artery stenosis, 413
Two-dimensional echocardiographic measurement of ejection fraction: what determines a good correlation? 452
Two-dimensional echocardiographic recognition of surgically remediable complications of acute myocardial infarction, 459
Two dimensional echocardiographic estimation of left ventricular volume in small newborn lamb hearts, 479
Ultrasonic detection of the altered acoustic properties of myocardium characteristic of adriamycin-induced cardiomyopathy, 471
Use of fetal echocardiography in the diagnosis and management of antenatal arrhythmias, 457

Ejection fraction
One minute multiple gated equilibrium scintigraphy for assessment of left ventricular ejection fraction and segmental wall motion: validation with state of the art instrumentation and optimized space-time smoothing, 454
Regional ejection fraction image (REFI)—an accurate method for the detection of coronary heart disease, 444
Two-dimensional echocardiographic measurement of ejection fraction: what determines a good correlation? 452
Electrocardiography
Arrhythmogenicity of encainide. The role of QT interval, 498
Confirmation of a new technique for detecting slow ventricular activation on the body surface, 488
Determination of cardiac dipole locations during ventricular recovery in normal men, 465
Distribution of body surface ECG potentials in familial QT interval prolongation, 480
Does myocardial scar size predict the electrocardiographic frontal plane axis? 464
Electrocardiographic "low voltage, anterior wall myocardial infarct pattern, arrhythmias and absence on left ventricular hypertrophy"—The characteristic electrocardiogram of amyloid heart disease from analysis of 40 necropsy patients, 465
How useful is the electrocardiogram as an indicator of coronary artery spasm? 449
Predictive value of the Minnesota code criteria for acute myocardial infarction: correlation with technetium 99m pyrophosphate scintigraphy and serum enzyme evaluation, 487
Q waves and transmural infarcts: the terms are not the same, 464
Electrocardiography, ambulatory
Efficacy of 24-hour ambulatory ECG monitoring as a predictor of sudden death in hypertrophic cardiomyopathy, 480
Prognostic value of ventricular arrhythmias, 397
Electrocardiography, exercise
Precordial electrocardiographic mapping in the identification of patients with left main stem disease, 423
Relation of exercise electrocardiographic ST changes to physiological measurements in men at high risk of future coronary death, 420
Sensitivity of exercise induced changes in apex of T to end of T and QT intervals for detecting coronary disease, 423
Electrolytes
Effect of prolonged prazosin treatment on the hemodynamics and cardiac electrolytes and Na^+-K^+ATPase in dogs with chronic aortic stenosis, 426
Electrophysiologic studies
Activation mapping in sinus rhythm in patients with ventricular tachycardia-relationship to cycle length and site or origin, 497
Additional evidence for adenosine mediation of A-V conduction disturbances in canine myocardium, 429
Analysis of antegrade and retrograde fast pathway properties in dual pathway patients, 434
Anatomic and electrophysiologic correlates of ventricular tachycardia requiring left ventricular stimulation, 448
Atrial excitability and conduction in patients prone to atrial fibrillation, 496
Atrial tachycardia. The paroxysmal versus the permanent form, 495
Autonomic modulation of A-V nodal conduction in conscious dogs, 428
Cardiac disease of myotonic muscular dystrophy, 421
Characterization of the onset of ectopic atrial tachycardia with A-V block, 496
Clinical and electrophysiologic prediction of need for pacemaker insertion in children with congenital complete atrioventricular block, 439
Closed chest permanent atrioventricular block in dogs: technique and anatomic changes, 428
Comparative effects of cycle length on ventricular refractoriness of normal and chronically infarcted myocardium, 391
Confirmation of a new technique for detecting slow ventricular activation on the body surface, 488
Differences in responsiveness of SA and AV node to vagal stimulation, 429
Disopyramide phosphate in Wolff-Parkinson-White syndrome, 495
Effect of interruption of collateral blood flow on conduction delay and arrhythmias during acute myocardial ischemia, 391
Effect of isoproterenol on "residual fast channel-dependent slow conduction" produced in guinea pig ventricular muscle, 475
Effect of overdrive pacing on electrically and neurologically isolated sinus node in otherwise intact dogs, 404
Effects of $[K+]_0$ on membrane potential, delayed afterdepolarizations and triggered activity in atrial fibers of the canine coronary sinus, 405
Electrical instability as a function of myocardial infarction size, 392
Electrophysiological mechanisms of AV conduction in response to atrial fibrillation revealed by multiple simultaneous extracellular and intracellular recordings, 429
Electrophysiologic assessment of patients with syncope, 433
Electrophysiologic effects of propafenone on canine ischemic cardiac cells, 483
Electrophysiologic studies before and after implantation of the automatic defibrillator, 397
Electrophysiologic studies before and after aortocoronary bypass in patients with out-of-hospital ventricular fibrillation, 497
Electrophysiology of the canine sinus node during cardiopulmonary bypass: technique for localization and response to cold cardioplegia, 405
Endocardial mapping of triggered automaticity in canine ischemic Purkinje fibers, 489
Enhanced vagal tone shortens atrial refractoriness and facilitates induction of repetitive atrial responses in man, 496
Estimation of ventricular repolarization duration and disparity from distributions of QRST area, 489
Estimation of ventricular transmembrane action potential durations and repolarization times from unipolar electrograms, 488
Excellular recording of diastolic slope in dogs and humans with his bundle rhythms, 405
Fragmented electrical activity-relationship to ventricular tachycardia, 448
Initiation of atrio-ventricular nodal re-entrant tachycardia in patients with discontinuous antegrade conduction curves. Importance of a discontinuous retrograde conduction curve, 434
Membrane current systems in the rabbit atrioventricular node. The first voltage clamp study, 429
Meobentine sulfate: antiarrhythmic efficacy and mechanism of action in a chronic canine model of myocardial infarction susceptible to ventricular tachyarrhythmias, 392
Multiple atrioventricular nodal pathways—a new electrophysiological phenomenon in children, 440
New method of recording transmembrane action potential from atria of in situ heart, 404
Nifedipine but not verapamil has age-independent effects on cardiac repolarization, 475
Nodal function in 30 patients with atrioventricular nodal 1/1 conduction above 200/mn, 433
Non-computerized on-line epicardial and intramural mapping of ventricular arrhythmias, 488
Noninvasive His bundle recording. Experience from three years of clinical trials, 465
Non-invasive serial electrophysiologic testing using an implanted pacemaker to track chest wall stimuli, 392
Non-uniform effects of sympathetic nerve stimulation on ventricular refractoriness in healed myocardial infarction: comparison to acute infarction, 436
Predictive value of programmed electrical stimulation in patients with sudden death or recurrent ventricular tachycardia, 397
Programmed premature stimulation as a guide to antiarrhythmic therapy for malignant ventricular arrhythmia in the absence of ambient ectopy, 497
Refractoriness of premature and nonpremature beats in the human ventricle, 448
Repetitive extrasystole as an index of vulnerability to ventricular fibrillation during myocardial ischemia, 391
Reproducibility of electrophysiologic responses to programmed ventricular stimulation during serial drug testing in patients with recurrent ventricular tachycardia, 449
Results of programmed stimulation in 80 patients having a history but no electrocardiographic documentation of tachycardia, 433
Significance of repetitive ventricular

responses induced by atrial and ventricular pacing in patients with and without ventricular tachycardia, 448
Simultaneous operation of multiple reentrant circuits during uniform ventricular tachycardia, 391
Sinus node excision—a study of atrial subsidiary pacemakers—a canine model of the sick sinus syndrome, 405
Sinus node function after cardiac transplantation, 496
Site of action of local anesthetics on heart fibers, 475
Slow ventricular activation detected on the body surface in patients with ventricular tachycardia after myocardial infarction, 498
Stabilizing effect of insulin on automaticity in partially depolarized cardiac Purkinje fibers, 475
Unexplained syncope: results of therapy based on electrophysiologic studies, 433

Encainide
Arrhythmogenicity of encainide. The role of QT interval, 498
Dose related haemodynamic effects of intravenous encainide, 483

Enzyme inhibitors
MK-421: a new oral angiotensin converting enzyme inhibitor for essential hypertension, 470

Exercise
Heart rate responses to home activities soon after myocardial infarction, 418
Myocardial blood flow at rest and during exercise in dogs with left ventricular hypertrophy, 446

Exercise testing
Abnormal blood pressure response during an exercise test, 423
Beneficial effects of diltiazem on exercise performance in patients with coronary artery disease and angina pectoris, 464
Changes in left ventricular volumes during upright exercise in patients with coronary artery disease, 468
Cold pressor thallium 201 myocardial scintigraphy in detection of coronary artery disease: an alternative to exercise scintigraphy, 444
Demonstation of exercise-induced ischemia without angina in patients who recover from out-of-hospital ventricular fibrillation, 445
Digitalis and exercise testing, a five year followup, 416
Divergent left ventricular response to exercise in children with left ventricular pressure or volume overload, 446
Does LV function reach a steady state during sustained exercise? 468
Effect of antihypertensive medications on physical work capacity, 415
Effect of rate-dependent left bundle branch block on left ventricular ejection fraction and regional wall motion, 415
Effect of verapamil on exercise-induced regional myocardial dysfunction in conscious dogs, 416
Effects of bedrest deconditioning on exercise ventricular function in middle-aged men, 477
Enhanced oxyhemoglobin dissociation contributes to unloading oxygen at rest and during exercise in severe chronic heart failure patients, 468
Errors of estimation of functional capacity in cardiac patients, 415
Exercise induced arterial hypotension—A normal response to severe exercise, 477
Exercise testing of women with chest pain with and without thallium tomography, 422
Exercise tolerance testing in adolescents with essential hypertension, 470
Gated radionuclide angiography during upright exercise in patients with programmable pacemakers, 435
Hemodynamic evaluation of the Fontan procedure at rest and with exercise, 432
Immediate post-exercise ventriculogram: a scintigraphic tool for the pre-operative assessment of reversible myocardial asynergy, 424
Left ventricular response to exercise after anterior myocardial infarction: differences between patients with single and multivessel coronary artery disease, 408
Long term effect of oral amrinone in heart failure: improvement in exercise performance despite declining left ventricular pump function, 428
Precordial electrocardiographic mapping in the identification of patients with left main stem disease, 423
Prognosis of patients with coronary artery disease by exercise testing, 415
Rest and exercise hemodynamics after Fontan procedure, 432
Sensitivity of exercise induced changes in apex of T to end of T and QT intervals for detecting coronary disease, 423
Similarity of the hemodynamic responses to static and dynamic handgrip, 477
Sympathetic response to exercise in patients with congestive heart failure, 395
Value of measuring anaerobic threshold during radionuclide exercise testing in aortic regurgitation, 473

Exercise training
Daily exercise augments antegrade flow following partial coronary occlusion, 467
Decreased myocardial oxygen demand from exercise training secondary to improved work efficiency: effect of habituation versus aerobic conditioning, 467
Echocardiographic changes during a 1 year exercise program in previously sedentary middle aged men, 477
Effect of exercise prescription on the recurrence rate of myocardial infarction in men, 419

Extrasystole
Repetitive extrasystole as an index of vulnerability to ventricular fibrillation during myocardial ischemia, 391

Familial disease
Distribution of body surface ECG potentials in familial QT interval prolongation, 480

Fibrosis
Correlations of fibrosis in left ventricular endomyocardial biopsies from patients with aortic valve disease, 421
Morphological-clinical correlates of myocardial fibrosis due to discrete subaortic stenosis in Newfoundland dogs, 447
Reduction of myocardial fibrosis by early methyl prednisone or ibuprofen administration in experimental radiation induced heart disease, 402

Flecainide acetate
Flecainide acetate, a new antiarrhythmic agent: dose-ranging and efficacy study, 482
Oral flecainide acetate for elimination of ventricular arrhythmias in man, 482

Fluorocarbons
Effects of fluorocarbons and supplemental oxygen on acute myocardial ischemia assessed by intramyocardial gas tension measurement, 436

Gas tension
Effects of fluorocarbons and supplemental oxygen on acute myocardial ischemia assessed by intramyocardial gas tension measurement, 436

Grafts
Clinical usefulness and feasibility of determining coronary artery bypass graft patency by contrast enhanced computed tomography during the early postoperative period, 495
Dissolution of coronary artery bypass graft thrombi by streptokinase infusion, 493
Effect of ibuprofen on platelet deposition in gore-tex and autologous vein grafts, 455
Improved graft patency with antiplatelet drugs in patients treated for one year following coronary bypass surgery, 494
Ten year experience with the internal mammary artery as a coronary bypass graft, 485

Graves' disease
Cardiac effects of plasma from patients with Graves' disease, 402

Heart block
Characterization of the onset of ectopic atrial tachycardia with A-V block, 496
Clinical and electrophysiologic prediction of need for pacemaker insertion in children with congenital complete atrioventricular block, 439
Closed chest permanent atrioventricular block in dogs: technique and anatomic changes, 428

Heart murmurs
Effect of acute aortic insufficiency on the dynamics of mitral valve motion and instantaneous trans-mitral flow: hemodynamic mechanism for the austin flint murmur, 426

Heart rate
Concentration dependent heart rate suppression with verapamil, 406

Heart rate responses to home activities soon after myocardial infarction, 418

Hematocrit

Haemodynamic effects of haematocrit reduction in patients with cyanotic congenital heart disease and secondary polycythaemia, 451

Hemodynamics

Aortic input impedance in mitral regurgitation, 426

Comparative hemodynamic and clinical responses to isuprel, diazoxide and hydralazine in severe precapillary pulmonary hypertension, 422

Divergent left ventricular response to exercise in children with left ventricular pressure or volume overload, 446

Dose related haemodynamic effects of intravenous encainide, 483

Effect of acute aortic insufficiency on the dynamics of mitral valve motion and instantaneous trans-mitral flow: hemodynamic mechanism for the austin flint murmur, 426

Effect of prolonged prazosin treatment on the hemodynamics and cardiac electrolytes and Na^+-K^+ATPase in dogs with chronic aortic stenosis, 426

Evidence for altered vascular reactivity in young subjects with labile, borderline hypertension, 469

Haemodynamic effects of haematocrit reduction in patients with cyanotic congenital heart disease and secondary polycythaemia, 451

Haemodynamic monitoring in painless myocardial ischaemia, 446

Hemodynamic effects of a new beta$_1$-agonist (prenalterol) in patients with congestive heart failure, 428

Hemodynamic effects of hydralazine in patients with isolated right ventricular failure, 390

Hemodynamic evaluation of the Fontan procedure at rest and with exercise, 432

Hemodynamic results following aortic valve replacement with the Hancock standard orifice bioprostheses, 440

Inotropic contractile reserve: a useful predictor of increased five year postoperative survival and improved left ventricular function in patients with coronary artery disease and a depressed ejection fraction, 495

Mechanisms of load independence of relaxation during hypoxia in mammalian cardiac muscle, 410

Potential value of oral β_2 adrenoceptor agonists in left ventricular failure, 427

Regurgitation of prosthetic heart valves: dependence on heart rate and cardiac output, 441

Rest and exercise hemodynamics after Fontan procedure, 432

Similarity of the hemodynamic responses to static and dynamic handgrip, 477

Systolic load dependency of left ventricular relaxation is influenced by beta adrenergic tone and abnormal synchrony, 410

His bundle

Excellular recording of diastolic slope in dogs and humans with his bundle rhythms, 405

Noninvasive His bundle recording. Experience from three years of clinical trials, 465

Hydralazine

Comparative hemodynamic and clinical responses to isuprel, diazoxide and hydralazine in severe precapillary pulmonary hypertension, 422

Hemodynamic effects of hydralazine in infants with large ventricular septal defect, 439

Hemodynamic effects of hydralazine in patients with isolated right ventricular failure, 390

Protective effects of verapamil and hydralazine on the cardiomyopathy of the Syrian hamster, 460

Hydrocortisone

Failure to reduce infarct size in the rat, 443

Hyperlipidemias

Plasmapheresis in the treatment of children with homozygotic type II hyperlipidemia, 419

Platelet activity in coronary disease, relationship to smoking and hyperlipidemia, 456

Program on the surgical control of the hyperlipidemias (POSCH): a status report, 400

Hyperlipoproteinemia

Hyperlipoproteinemia (HLP) as a significant risk factor for pulmonary embolism (PE) in coronary artery bypass (CABG) patients, 494

Hypertension

Age-dependent enhancement of vascular phospholipid (PL) deacylation-reacylation cycle in spontaneously hypertensive rats (SHRs), 478

An experimental model to demonstrate objectively the association of labile hypertension to vascular complication, 478

Cardiac rhythm, arterial pressure, and urinary catecholamines in hypertension with and without left ventricular hypertrophy, 480

Diastolic ventricular abnormality in hypertensive heart disease: atrial emptying index, 469

Echocardiographic evidence for early left ventricular hypertrophy in renal hypertensive dogs, 478

Effective and safe treatment of hypertensive crisis with nifedipine, 469

Effect of beta blockade therapy on hypertensive cardiac hypertrophy, 469

Effect of dietary sodium and potassium content on sympathetic activity in spSHR, 478

Evidence for altered vascular reactivity in young subjects with labile, borderline hypertension, 469

Exercise tolerance testing in adolescents with essential hypertension, 470

Labetalol therapy in angina pectoris and systemic hypertension: effects of combined alpha-beta adrenergic blockade, 430

MK-421: a new oral angiotensin converting enzyme inhibitor for essential hypertension, 470

Hypertension, pulmonary

Comparative hemodynamic and clinical responses to isuprel, diazoxide and hydralazine in severe precapillary pulmonary hypertension, 422

Natural history of idiopathic pulmonary hypertension, 422

Hypertrophy

Cardiac rhythm, arterial pressure, and urinary catecholamines in hypertension with and without left ventricular hypertrophy, 480

Echocardiographic evidence for early left ventricular hypertrophy in renal hypertensive dogs, 478

Effect of beta blockade therapy on hypertensive cardiac hypertrophy, 469

Myocardial blood flow at rest and during exercise in dogs with left ventricular hypertrophy, 446

Myomectomy and mitral valve replacement for idiopathic hypertrophic subaortic stenosis: five year follow-up, 424

Hyperventilation test

Coronary vasospasm provoked by the hyperventilation test, 450

Hypoglycemia

Inotropic and chronotropic effects of insulin in the conscious dog: contribution of catecholamines and hypoglycemia, 460

Hypotension

Exercise induced arterial hypotension—A normal response to severe exercise, 477

Hypothermia

Hypothermic retroperfusion treatment of acute myocardial ischemia: effects on cardiac function and infarct size, 436

Hypoxia

Mechanisms of load independence of relaxation during hypoxia in mammalian cardiac muscle, 410

Ibuprofen

Effect of ibuprofen on platelet deposition in gore-tex and autologous vein grafts, 455

Failure to reduce infarct size in the rat, 443

Platelet thrombus formation is stenosed canine coronary arteries and their inhibition with ibuprofen, 456

Reduction of myocardial fibrosis by early methyl prednisone or ibuprofen administration in experimental radiation induced heart disease, 402

Immune response

Inhibition of leukocyte migration by mononuclear cell supernatants from patients with ischemic heart disease, 452

Inferior vena cava

Inferior vena caval ultrasonagraphy: its use in the assessment of right heart function, 453

Insulin

Inotropic and chronotropic effects of insulin in the conscious dog: contribution of catecholamines and hypoglycemia, 460

Reversal of diabetic cardiomyopathy by insulin treatment, 460

Reversibility of diabetic cardiomyopathy with insulin in rats, 414

Stabilizing effect of insulin on automaticity in partially depolarized

cardiac Purkinje fibers, 475
Interventricular septum
Preservation of interventricular septal function in patients having coronary artery bypass grafts without cardiopulmonary bypass, 394
Ischemia
Brief repeat periods of ischemia have a cumulative effect and may cause myocardial necrosis, 445
Comparative effects of intermittent ischemic arrest and potassium cardioplegia on diastolic ventricular compliance in patients, 417
Cross-sectional echocardiography in the early detection of acute myocardial ischaemia and infarction, 404
Demonstation of exercise-induced ischemia without angina in patients who recover from out-of-hospital ventricular fibrillation, 445
Divergent effects of inotropic stimulation on the mechanical function of the ischemic and the severely depressed reperfused myocardium, 442
Effect of interruption of collateral blood flow on conduction delay and arrhythmias during acute myocardial ischemia, 391
Effect of prostacyclin on ventricular arrhythmias and intracardiac conduction in myocardial ischemia, 437
Effects of fluorocarbons and supplemental oxygen on acute myocardial ischemia assessed by intramyocardial gas tension measurement, 436
Endocardial mapping of triggered automaticity in canine ischemic Purkinje fibers, 489
Evaluation of infarcted and ischemic myocardium with 18-fluorodeoxyglucose, $^{13}NH_3$, and positron computed tomography, 481
Exacerbation of ischemia in vasotonic angina pectoris by propranolol, 463
Haemodynamic monitoring in painless myocardial ischaemia, 446
High frequency epicardial echo mapping of segmental myocardial performance at multiple sites on right and left ventricles, 403
How does systolic coronary artery compression cause myocardial ischemia in dogs? 473
Hypothermic retroperfusion treatment of acute myocardial ischemia: effects on cardiac function and infarct size, 436
Importance of early administration of intravenous nitroglycerin to preserve ischemic myocardium, 490
Inhibition of leukocyte migration by mononuclear cell supernatants from patients with ischemic heart disease, 452
Kinetics of C-11 labeled palmitate in ischemic myocardium, 414
Left ventricular contractile failure following hypothermic ischemic arrest: protection by coronary artery washout, 414
Metabolic characterization of reversible versus irreversible ischemic damage, 436
Nifedipine therapy for recurrent ischemic pain following acute myocardial infarction, 490
Nitroprusside improves coronary perfusion in regional ischemia in conscious dogs with normal and high left ventricular diastolic pressure, 442
Positive labeling of ischemic myocardium: a new approach in patients with coronary disease, 481
Protection of ischemic myocardium by diltiazem, 442
Quantification of regional myocardial blood content in normal, ischemic and reperfused myocardium, 445
Repetitive extrasystole as an index of vulnerability to ventricular fibrillation during myocardial ischemia, 391
Right atrial pacing soon after MI: detection of residual myocardial ischemia and prediction of early prognosis, 419
Significance of biphasic R wave amplitude changes during incremental atrial pacing: a sensitive and specific marker for acute myocardial ischemia, 423
Two-dimensional echocardiographic assessment of wall thinning and its relation to perfusion during graded coronary stenosis, 403
Isoproterenol
Effect of isoproterenol on "residual fast channel-dependent slow conduction" produced in guinea pig ventricular muscle, 475
Isosorbide dinitrate
Benefits of added nifedipine in unstable angina persisting despite beta blockade and isosorbide dinitrate, 399
Isuprel
Comparative hemodynamic and clinical responses to isuprel, diazoxide and hydralazine in severe precapillary pulmonary hypertension, 422

Kawasaki disease
Cardiac involvement with Kawasaki disease in children from New England, 457

Labetalol
Labetalol therapy in angina pectoris and systemic hypertension: effects of combined alpha-beta adrenergic blockade, 430
Reduction of myocardial ischemia by balanced alpha and beta blockade with labetalol, 430
Leukocytes
Inhibition of leukocyte migration by mononuclear cell supernatants from patients with ischemic heart disease, 452
Lidocaine
Mexiletine for resistant ventricular tachycardia: comparison with lidocaine and enhancement of efficacy by combination with quinidine, 438
Lipoproteins
Alterations in plasma lipoprotein levels during high mileage running, 468
High density lipoprotein and total cholesterol as predictors of 7-year mortality from coronary heart disease, cancer and all causes, 486
Locust bean gum
Familial hypercholesterolemic families' response to food products containing LBG, 487
Lung disease
Effect of terbutaline on right and left ventricular function and size in obstructive lung disease, 491
Lungs
Transmission of echocardiographic contrast through the lungs, 470
Transmission of echocardiographic contrast through the lungs. II: human studies, 470
Lupus erythematosus
Systemic lupus erythematosus and ischemic coronary artery disease, 446
Lysophosphatides
Metabolism of arrhythmogenic lysophosphatides in rabbit myocardium, 413

Mapping
Activation mapping in sinus rhythm in patients with ventricular tachycardia-relationship to cycle length and site or origin, 497
Endocardial mapping of triggered automaticity in canine ischemic Purkinje fibers, 489
Endocardial pace-mapping to localize the origin of ventricular tachycardia, 488
Non-computerized on-line epicardial and intramural mapping of ventricular arrhythmias, 488
Surgical therapy for right ventricular tachycardia, 497
Meobentine sulfate
Meobentine sulfate: antiarrhythmic efficacy and mechanism of action in a chronic canine model of myocardial infarction susceptible to ventricular tachyarrhythmias, 392
Metabolism
Flow-independent characteristics of externally detectable cardiac kinetics of ^{11}C-palmitate, 414
Kinetics of C-11 labeled palmitate in ischemic myocardium, 414
Left ventricular contractile failure following hypothermic ischemic arrest: protection by coronary artery washout, 414
Metabolic characterization of reversible versus irreversible ischemic damage, 436
Metabolism of arrhythmogenic lysophosphatides in rabbit myocardium, 413
Phosphorylation of cardiac sarcoplasmic reticulum (SR) by a calcium-activated, phospholipid-dependent protein kinase, 413
β^+-Probe documentation of a direct relation between clearance of ^{11}C-palmitate and myocardial metabolism, 481
Saturable metabolism of perhexiline maleate: correlations with long-term toxicity, 399
Methyl prednisone
Reduction of myocardial fibrosis by early methyl prednisone or ibuprofen administration in experimental radiation induced heart disease, 402

Mexiletine
Mexiletine for resistant ventricular tachycardia: comparison with lidocaine and enhancement of efficacy by combination with quinidine, 438
Mitral regurgitation
Aortic input impedance in mitral regurgitation, 426
Left ventricular dysfunction in patients with mitral regurgitation, 410
Left ventricular function and stiffness before and after successful surgery for mitral regurgitation, 427
Systolic mechanics during surgical correction of chronic mitral regurgitation, 427
Mitral stenosis
Right and left ventricular performance before and after correction of mitral stenosis, 424
Mitral valve
Effect of acute aortic insufficiency on the dynamics of mitral valve motion and instantaneous trans-mitral flow: hemodynamic mechanism for the austin flint murmur, 426
Two-dimensional echocardiographic identification of prolapse of individual scallops of posterior mitral leaflet, 412
Mitral valve disease
Abnormal mitral annular contraction in cardiomyopathies and correlation with left ventricular function, 409
Mitral valve prolapse
Idiopathic prolapse of the mitral valve: follow-up study of 136 patients studied by angiography, 426
Prolonged QT interval and autonomic imbalance: a clue for the prevention of sudden death in mitral valve prolapse, 480
MK-421
MK-421: a new oral angiotensin converting enzyme inhibitor for essential hypertension, 470
Muscular dystrophy
Cardiac disease of myotonic muscular dystrophy, 421
Myocardial contractility
New technique for the simultaneous assessment of myocardial perfusion and contractility in man, 394
Myocardial disease
Use of transvenous myocardial biopsy to diagnose and accurately evaluate diseases of the myocardium, 499
Myocardial function
High frequency epicardial echo mapping of segmental myocardial performance at multiple sites on right and left ventricles, 403
Myocardial imaging
Thallium-201 myocardial perfusion imaging in women: correlation with coronary arteriography, 422
Myocardial infarct
Calcium antagonists: their effectiveness in decreasing the occurence of ventricular fibrillation and reducing infarct size after a coronary artery occlusion, 443
Electrical instability as a function of myocardial infarction size, 392
Failure to reduce infarct size in the rat, 443
Hypothermic retroperfusion treatment of acute myocardial ischemia: effects on cardiac function and infarct size, 436
Myocardial infarct extension: diagnosis, incidence, and clinical significance, 418
Myocardial infarct extension: reassessment of incidence, detection and influence on survival, 418
Quantitation of experimental canine myocardial infarct size with technetium stannous pyrophosphate: a comparison of multipinhole and rotating slant hole emission tomography, 443
Reduction in infarct size and morbidity by early intravenous betablockade, 490
Myocardial infarction
Anterior transmural myocardial infarction (AMI). Analysis of regional wall motion during the early hours with and without total coronary occlusion, 459
Cigarette smoking and non-fatal myocardial infarction in women, 420
Comparative effects of cycle length on ventricular refractoriness of normal and chronically infarcted myocardium, 391
Confirmation of a new technique for detecting slow ventricular activation on the body surface, 488
Consistent platelet activation associated with early recurrent myocardial infarction, 456
Does myocardial scar size predict the electrocardiographic frontal plane axis? 464
Effect of exercise prescription on the recurrence rate of myocardial infarction in men, 419
Effects of nitroglycerin on intracoronary platelet aggregation and ventricular vulnerability during partial coronary stenosis, 489
Frequency of provoked coronary arterial spasm in patients with recent transmural myocardial infarction, 490
Heart rate responses to home activities soon after myocardial infarction, 418
Importance of early administration of intravenous nitroglycerin to preserve ischemic myocardium, 490
Influence of nifedipine on myocardial blood flow in the ischemic and lateral border zones, 442
Left ventricular response to exercise after anterior myocardial infarction: differences between patients with single and multivessel coronary artery disease, 408
Mechanism of low output in experimental right ventricular infarction, 437
Meobentine sulfate: antiarrhythmic efficacy and mechanism of action in a chronic canine model of myocardial infarction susceptible to ventricular tachyarrhythmias, 392
Murine Coxsackievirus B4 cardiomyopathy; myocardial infarction and ventricular aneurysms, 421
Myocardial infarct extension: diagnosis, incidence, and clinical significance, 418
Myocardial infarct extension: reassessment of incidence, detection and influence on survival, 418
Non transmural (subendocardial) myocardial infarction in man: the prevalence of total coronary occlusion, 459
Nontransmural vs transmural myocardial infarction: is there a difference? 459
Non-uniform effects of sympathetic nerve stimulation on ventricular refractoriness in healed myocardial infarction: comparison to acute infarction, 436
Predicting the extent and location of coronary disease two-weeks post-myocardial infarction by thallium-201 scintigraphy, 484
Prevalence and significance of ventricular tachycardia in the late hospital phase of myocardial infarction, 397
Prognosis after infarct: stratification by Q wave evolution, 465
Q waves and transmural infarcts: the terms are not the same, 464
"Reflow" and "no-reflow" myocardial infarction, 492
Right atrial pacing soon after MI: detection of residual myocardial ischemia and prediction of early prognosis, 419
Right ventricular infarction: clinical course and follow-up, 458
Role of two-dimensional echocardiography in evaluation of patients with post myocardial infarction ventricular septal defect, 461
Salvage of jeopardized myocardium by non-surgical reperfusion (NSR) in man, 493
Serial evaluation of right ventricular function after right ventricular infarction, 458
Slow ventricular activation detected on the body surface in patients with ventricular tachycardia after myocardial infarction, 498
Transluminal recanalization during evolving myocardial infarct in man, 492
Unstable angina: effect of medical versus surgical therapy on survival and myocardial infarction, 486
Vascular determinants of early recurrent myocardial infarction, 418
Myocardial infarction, acute
Cross-sectional echocardiography in the early detection of acute myocardial ischaemia and infarction, 404
Discrete intramural sonolucency: a new echocardiographic finding in acute myocardial infarction, 404
Early and late proteolysis in acute myocardial infarction, 437
Intracoronary streptokinase in acute myocardial infarction: assessment by T1-201 scintigraphy, 493
Lysis of coronary artery thrombosis with intracoronary streptokinase in acute myocardial infarction, 493
Nifedipine therapy for recurrent ischemic pain following acute myocardial infarction, 490
Pain relief in acute myocardial infarction by intravenous atenolol, 489
Predictive value of the Minnesota code criteria for acute myocardial infarction: correlation with technetium 99m pyrophosphate scintigraphy and serum enzyme evaluation, 487
Prognosis of men after first acute myocardial infarction in the 1960's and 1970's: search for a secular trend, 487
Two-dimensional echocardiographic recognition of surgically remediable complications of acute myocardial infarction, 459

Myocardial ischemia
Reduction of myocardial ischemia by balanced alpha and beta blockade with labetalol, 430
Myocardial perfusion
Increase in regional myocardial perfusion post-coronary artery bypass grafting, 417
New technique for the simultaneous assessment of myocardial perfusion and contractility in man, 394
Quantitative regional myocardial perfusion scanning with contract echocardiography, 403
Myocardium
Additional evidence for adenosine mediation of A-V conduction disturbances in canine myocardium, 429
Divergent effects of inotropic stimulation on the mechanical function of the ischemic and the severely depressed reperfused myocardium, 442
Effect of verapamil on the diastolic mechanics of the left ventricle, 411
Enhanced myocardial preservation in animals and man with nifedipine and cardioplegia, 416
Quantification of regional myocardial blood content in normal, ischemic and reperfused myocardium, 445

Nifedipine
Benefits of added nifedipine in unstable angina persisting despite beta blockade and isosorbide dinitrate, 399
Comparison of verapamil and nifedipine in patients with Prinzmetal's variant angina pectoris, 398
Does nifedipine protect against reperfusion damage? 461
Effective and safe treatment of hypertensive crisis with nifedipine, 469
Effects of verapamil and nifedipine on left ventricular function in patients with Prinzmetal's variant angina, 394
Enhanced myocardial preservation in animals and man with nifedipine and cardioplegia, 416
Influence of nifedipine on myocardial blood flow in the ischemic and lateral border zones, 442
Influence of nifedipine on myocardial blood flow during three grades of coronary occlusion, 472
Nifedipine but not verapamil has age-independent effects on cardiac repolarization, 475
Nifedipine therapy for recurrent ischemic pain following acute myocardial infarction, 490
Sustained beneficial effect of nifedipine in chronic refractory heart failure, 407
Nitroglycerin
Effects of nitroglycerin on intracoronary platelet aggregation and ventricular vulnerability during partial coronary stenosis, 489
Importance of early administration of intravenous nitroglycerin to preserve ischemic myocardium, 490
Inhibition of nitroglycerin effect in humans by suppression of prostaglandin E, 390
Thallium-201 redistribution scintigraphy predicts the response to left ventricular asynergic segments to nitroglycerin administration, 484
Nitroprusside
Nitroprusside improves coronary perfusion in regional ischemia in conscious dogs with normal and high left ventricular diastolic pressure, 442
Normal values
Determination of cardiac dipole locations during ventricular recovery in normal men, 465
Effects of bedrest deconditioning on exercise ventricular function in middle-aged men, 477
Heterogeneity of segmental left ventricular wall thickening and excursion in two-dimensional echocardiograms of normal humans, 452
Nuclear medicine
Accuracy of radionuclide angiocardiography in the diagnosis of coronary artery disease—a prospective study, 444
Adverse prognostic significance of an abnormal thallium myocardial perfusion scintigram, 483
Clinical utility of cold pressor radionuclide ventriculography in coronary artery disease, 444
Cold pressor thallium 201 myocardial scintigraphy in detection of coronary artery disease: an alternative to exercise scintigraphy, 444
Computerized axial tomography of the thorax: size of right pulmonary artery in right ventricular outflow tract obstruction, 458
Correlation of cineangiography and blood pool scan for measurement of left ventricular volume in human cadaver hearts, 455
Detection of abnormal pulmonary capillary wedge pressure from the distribution of regional pulmonary blood volume on the gated blood pool scan, 455
Detection of left ventricular thrombi by radionuclide angiography, 474
Direct measurement of cardiac output by gated equilibrium blood pool scintigraphy, 454
Evaluation of infarcted and ischemic myocardium with 18-fluorodeoxyglucose, $^{13}NH_3$, and positron computed tomography, 481
Failure of aspirin to prevent incorporation of indium labelled platelets into cardiac thrombi in man, 455
Gated radionuclide angiography during upright exercise in patients with programmable pacemakers, 435
Indium-III platelet scintigraphy and two dimensional echocardiography in the diagnosis of left ventricular thrombi, 474
One minute multiple gated equilibrium scintigraphy for assessment of left ventricular ejection fraction and segmental wall motion: validation with state of the art instrumentation and optimized space-time smoothing, 454
Positive labeling of ischemic myocardium: a new approach in patients with coronary disease, 481
Predicting the extent and location of coronary disease two-weeks post-myocardial infarction by thallium-201 scintigraphy, 484
β^+-Probe documentation of a direct relation between clearance of ^{11}C-palmitate and myocardial metabolism, 481
Quantification of valvular regurgitation before and after medical and surgical therapy by radionuclide angiography, 498
Quantitation of experimental canine myocardial infarct size with technetium stannous pyrophosphate: a comparison of multipinhole and rotating slant hole emission tomography, 443
Quantitation of left ventricular output in patients with and without left-sided valvular regurgitation using equilibrium radionuclide ventriculography, 454
Quantitation of myocardial perfusion in man using oxygen-15 and positron tomography, 481
Quantitative analysis of stress distribution and washout of T1-201 myocardial scintigrams: superiority over visual assessment for evaluation of coronary artery disease, 443
Radionuclide angiocardiographic assessment of patients following repair of transposition of the great arteries, 473
Radionuclide assessment of left ventricular function in patients with tricuspid atresia, 431
Radionuclide determination of left ventricular volume: comparison of counts-based and geometric methods, 454
Radionuclide evaluation of RV and LV function (FX) in children-cineangiographic validation and observations in transposition of the great arteries (TGA), 458
Radionuclide ventriculography following resuscitation from out-of-hospital ventricular fibrillation, 474
Regional ejection fraction image (REFI)—an accurate method for the detection of coronary heart disease, 444
Relationship of thallium-201 perfusion images to regional myocardial blood flow in man, 484
Serial radionuclide assessment of doxorubicin cardiotoxicity in cancer patients with abnormal baseline resting left ventricular performance, 474
Serial right ventricular thallium imaging following dipyridamole and relationship to right coronary artery disease, 484
Thallium-201 redistribution scintigraphy predicts the response to left ventricular asynergic segments to nitroglycerin administration, 484
Utility of serial thallium imaging following dipyridamole, 483
Value of measuring anaerobic threshold during radionuclide exercise testing in aortic regurgitation, 473

Oxygen
Decreased myocardial oxygen demand from exercise training secondary to improved work efficiency: effect of habituation versus aerobic conditioning, 467
Effect of dopamine and dobutamine on

regional blood flow, myocardial oxygen consumption and high energy phosphate compounds during cardiopulmonary bypass, 416
Effects of fluorocarbons and supplemental oxygen on acute myocardial ischemia assessed by intramyocardial gas tension measurement, 436
Enhanced oxyhemoglobin dissociation contributes to unloading oxygen at rest and during exercise in severe chronic heart failure patients, 468
Quantitation of myocardial perfusion in man using oxygen-15 and positron tomography, 481

Oxyhemoglobin
Enhanced oxyhemoglobin dissociation contributes to unloading oxygen at rest and during exercise in severe chronic heart failure patients, 468

Pacemakers
Assessment of clinical efficacy of a multiparameter programmable pulse generator, 393
Automatic cycle length adjustment–A versatile pacemaker for tachycardia termination, 476
Clinical and electrophysiologic prediction of need for pacemaker insertion in children with congenital complete atrioventricular block, 439
Gated radionuclide angiography during upright exercise in patients with programmable pacemakers, 435
Non-invasive correction of pacing system malfunctions by multiprogrammable pacemakers, 393
Non-invasive serial electrophysiologic testing using an implanted pacemaker to track chest wall stimuli, 392
Operative revision reduction with output programmable pulse generators, 393
Two years' clinical experience with a self-searching tachycardia pacemaker, 476

Pacing, atrial
Autodecremental atrial pacing for tachycardia termination-a clinical evaluation, 435
Right atrial pacing soon after MI: detection of residual myocardial ischemia and prediction of early prognosis, 419
Significance of biphasic R wave amplitude changes during incremental atrial pacing: a sensitive and specific marker for acute myocardial ischemia, 423
Significance of repetitive ventricular responses induced by atrial and ventricular pacing in patients with and without ventricular tachycardia, 448

Pacing, atrioventricular sequential
Non-invasive evaluation of cerebral blood flow during ventricular and A-V sequential pacing, 435

Pacing, cardiac
Benefits and risks of combined burst pacing and drug therapy of recurrent ventricular tachycardia, 476
Diagnosis of pacing catheter perforation by real time two-dimensional echocardiography, 462
Endocardial pace-mapping to localize the origin of ventricular tachycardia, 488
Evaluation of pacing function by real time two-dimensional echocardiography, 434
Fifteen year comparative study of cardiac pacing costs, 392
Long-term effectiveness of dual-demand sequential pacing for automatic conversion and prevention of refractory reentry supraventricular tachycardia, 476
P synchronous pacing: a new orthogonal approach to P-wave sensing, 434
Sinus node dysfunction in spinal cord injury with quadriplegia, 393
Use of stimulus-T interval to determine cardiac pacing rate, 435

Pacing, ventricular
Non-invasive evaluation of cerebral blood flow during ventricular and A-V sequential pacing, 435
Significance of repetitive ventricular responses induced by atrial and ventricular pacing in patients with and without ventricular tachycardia, 448

Palmitate
β^+-Probe documentation of a direct relation between clearance of ^{11}C-palmitate and myocardial metabolism, 481

Papillary muscles
Myocyte disarray develops in papillary muscles released from normal tension after mitral valve replacement, 409

Pediatric cardiology
A-B coronary-prone behavior pattern and cardiovascular risk factor variables in children and adolescents: the Bogalusa heart study, 419
Blood pressure related echocardiographic changes in adolescents and young adults, 420
Cardiac involvement with Kawasaki disease in children from New England, 457
Clinical and electrophysiologic prediction of need for pacemaker insertion in children with congenital complete atrioventricular block, 439
Collaborative study of blade atrial septostomy, 439
Complete atrioventricular canal associated with tetralogy of Fallot, 467
Computerized axial tomography of the thorax: size of right pulmonary artery in right ventricular outflow tract obstruction, 458
Divergent left ventricular response to exercise in children with left ventricular pressure or volume overload, 446
Echocardiographic and angiocardiographic features before and after the Jatene procedure (arterial switch) for transposition of the great arteries, 431
Echocardiographic diagnosis of absent pulmonary valve syndrome in the neonate, 479
Effect of age and cyanosis on the protein binding of quinidine in the pediatric patient, 440
Exercise tolerance testing in adolescents with essential hypertension, 470
Five year follow-up of aortic homograft monocusps used in reconstruction of the right ventricular outflow tract in infants with tetralogy of Fallot, 466
Hemodynamic effects of hydralazine in infants with large ventricular septal defect, 439
Hemodynamic evaluation of the Fontan procedure at rest and with exercise, 432
Late results of operation for discrete subaortic stenosis, 432
Morphological-clinical correlates of myocardial fibrosis due to discrete subaortic stenosis in Newfoundland dogs, 447
Morphologic basis for electrocardiographic evidence of conduction system involvement in Duchenne's Muscular Dystrophy (DMD), 402
Morphologic features of the ductus arteriosus after PGE_1 administration for ductus dependent congenital heart disease, 447
Morphometric analysis of lung biopsy tissue in candidates for Fontan-type surgical procedures, 447
Multiple atrioventricular nodal pathways—a new electrophysiological phenomenon in children, 440
Mustard's operation in the first month of life, 466
Myocardial blood flow at rest and during exercise in dogs with left ventricular hypertrophy, 446
Plasmapheresis in the treatment of children with homozygotic type II hyperlipidemia, 419
Prospective diagnosis of conotruncal malformations in infants using subxiphoid two-dimensional echocardiography, 457
Pulmonary valve atresia: diagnosis by pulse Doppler/two-dimensional echocardiography, 457
Radionuclide assessment of left ventricular function in patients with tricuspid atresia, 431
Radionuclide evaluation of RV and LV function (FX) in children-cineangiographic validation and observations in transposition of the great arteries (TGA), 458
Reciprocal development of 4th and 6th aortic arches in pulmonary atresia with ventricular septal defect, 447
Rest and exercise hemodynamics after Fontan procedure, 432
Safety and efficacy of short and long term verapamil therapy in children with tachycardia, 439
Tetralogy of Fallot: 11 year experience in New England, 432
Two dimensional echocardiographic estimation of left ventricular volume in small newborn lamb hearts, 479
Use of fetal echocardiography in the diagnosis and management of antenatal arrhythmias, 457

Perhexiline maleate
Saturable metabolism of perhexiline maleate: correlations with long-term toxicity, 399

Pericardial effusion
Shifts in left and right ventricular diastolic pressure-volume curves due to pericardial effusion and tamponade, 411

Pericarditis
Differentiation of constrictive pericarditis and restrictive cardiomyopathy by echocardiography, 462
Pericardium
Quantification of pericardial influences on diastolic filling of the left ventricle, 411
Phentolamine
Assessment of prazosin alpha receptor blockade with phentolamine: acute, subacute and late hemodynamic evaluation during sustained beneficial vasodilator therapy in congestive heart failure, 390
Pirbuterol
Potential value of oral β_2 adrenoceptor agonists in left ventricular failure, 427
Plasma
Cardiac effects of plasma from patients with Graves' disease, 402
Polycythemia
Haemodynamic effects of haematocrit reduction in patients with cyanotic congenital heart disease and secondary polycythaemia, 451
Potassium
Effect of dietary sodium and potassium content on sympathetic activity in spSHR, 478
Effects of $[K+]_0$ on membrane potential, delayed afterdepolarizations and triggered activity in atrial fibers of the canine coronary sinus, 405
Prazosin
Assessment of prazosin alpha receptor blockade with phentolamine: acute, subacute and late hemodynamic evaluation during sustained beneficial vasodilator therapy in congestive heart failure, 390
Direct effects of prazosin on the canine sinus node, 389
Effect of prolonged prazosin treatment on the hemodynamics and cardiac electrolytes and Na^+-K^+ATPase in dogs with chronic aortic stenosis, 426
Mechanism of transient prazosin hemodynamic "tachyphylaxis" in heart failure: acute, subacute and late serial evaluation of alpha receptor responses with phenylephrine by cardiac catheterization during prolonged oral prazosin therapy, 389
Prealbumin
Prealbumin is a component of senile cardiac amyloid, 421
Prenalterol
Comparative cardiocirculatory actions of new selective beta-1 agonist prenalterol vs dobutamine: demonstration of equivalent beneficial effects on cardiac pump performance in congestive heart failure, 492
Hemodynamic effects of a new $beta_1$-agonist (prenalterol) in patients with congestive heart failure, 428
Procainamide
Contrasting effects of procainamide and verapamil on intraventricular conduction and reentry, 449
Propranolol
Double-blind, randomized, placebo-controlled comparison of propranolol and verapamil in patients with stable, exertional angina pectoris, 463
Effects of moderate and high dose propranolol on ventricular function in patients with coronary artery disease, 430
Exacerbation of ischemia in vasotonic angina pectoris by propranolol, 463
Oral verapamil vs propranolol in coronary artery disease: evaluation of left ventricular function by exercise radionuclide ventriculography, 463
Persistent myocardial propranolol levels in man, 430
Prevention of postoperative supraventricular tachyarrhythmia in coronary bypass patients, with low-dose propranolol, 431
Ventricular fibrillation threshold during propranolol withdrawal, 431
Prostacyclin
Effect of prostacyclin on ventricular arrhythmias and intracardiac conduction in myocardial ischemia, 437
Effects of prostacyclin (PGI_2) on coronary blood flow in open-chest dogs after different routes of administration, 472
Prostaglandin E
Morphologic features of the ductus arteriosus after PGE_1 administration for ductus dependent congenital heart disease, 447
Prostaglandins
Inhibition of nitroglycerin effect in humans by suppression of prostaglandin E, 390
Proteolysis
Early and late proteolysis in acute myocardial infarction, 437
Pulmonary arteries
Two dimensional echocardiographic evaluation of branch pulmonary artery stenosis, 413
Pulmonary atresia
Reciprocal development of 4th and 6th aortic arches in pulmonary atresia with ventricular septal defect, 447
Pulmonary capillary wedge pressure
Detection of abnormal pulmonary capillary wedge pressure from the distribution of regional pulmonary blood volume on the gated blood pool scan, 455
Pulmonary embolism
Hyperlipoproteinemia (HLP) as a significant risk factor for pulmonary embolism (PE) in coronary artery bypass (CABG) patients, 494
Pulmonary valve disease
Pulmonary valve atresia: diagnosis by pulse Doppler/two-dimensional echocardiography, 457
Purkinje fibers
Endocardial mapping of triggered automaticity in canine ischemic Purkinje fibers, 489
Stabilizing effect of insulin on automaticity in partially depolarized cardiac Purkinje fibers, 475

Quinidine
Effect of age and cyanosis on the protein binding of quinidine in the pediatric patient, 440
Mexiletine for resistant ventricular tachycardia: comparison with lidocaine and enhancement of efficacy by combination with quinidine, 438
Q waves
Prognosis after infarct: stratification by Q wave evolution, 465
Q waves and transmural infarcts: the terms are not the same, 464

Risk factors
A-B coronary-prone behavior pattern and cardiovascular risk factor variables in children and adolescents: the Bogalusa heart study, 419
Cigarette smoking and non-fatal myocardial infarction in women, 420
High density lipoprotein and total cholesterol as predictors of 7-year mortality from coronary heart disease, cancer and all causes, 486
Hyperlipoproteinemia (HLP) as a significant risk factor for pulmonary embolism (PE) in coronary artery bypass (CABG) patients, 494
Relation of exercise electrocardiographic ST changes to physiological measurements in men at high risk of future coronary death, 420
Relationship between plasma testosterone and lipoprotein cholesterol, 420
Running
Alterations in plasma lipoprotein levels during high mileage running, 468

Salbutamol
Potential value of oral β_2 adrenoceptor agonists in left ventricular failure, 427
Scintigraphy
Adverse prognostic significance of an abnormal thallium myocardial perfusion scintigram, 483
Cold pressor thallium 201 myocardial scintigraphy in detection of coronary artery disease: an alternative to exercise scintigraphy, 444
Correlation of cineangiography and blood pool scan for measurement of left ventricular volume in human cadaver hearts, 455
Detection of abnormal pulmonary capillary wedge pressure from the distribution of regional pulmonary blood volume on the gated blood pool scan, 455
Direct measurement of cardiac output by gated equilibrium blood pool scintigraphy, 454
Failure of aspirin to prevent incorporation of indium labelled platelets into cardiac thrombi in man, 455
Indium-III platelet scintigraphy and two dimensional echocardiography in the diagnosis of left ventricular thrombi, 474
Intracoronary streptokinase in acute myocardial infarction: assessment by T1-201 scintigraphy, 493
One minute multiple gated equilibrium scintigraphy for assessment of left ventricular ejection fraction and

segmental wall motion: validation with state of the art instrumentation and optimized space-time smoothing, 454
Predicting the extent and location of coronary disease two-weeks post-myocardial infarction by thallium-201 scintigraphy, 484
Quantitative analysis of stress distribution and washout of T1-201 myocardial scintigrams: superiority over visual assessment for evaluation of coronary artery disease, 443
Radionuclide determination of left ventricular volume: comparison of counts-based and geometric methods, 454
Relationship of thallium-201 perfusion images to regional myocardial blood flow in man, 484
Serial right ventricular thallium imaging following dipyridamole and relationship to right coronary artery disease, 484
Thallium-201 redistribution scintigraphy predicts the response to left ventricular asynergic segments to nitroglycerin administration, 484
Utility of serial thallium imaging following dipyridamole, 483

Shunts
Operability of adults with left to right shunts, cyanosis, and pulmonary vascular obstruction, 424

Sick sinus syndrome
Sinus node excision—a study of atrial subsidiary pacemakers—a canine model of the sick sinus syndrome, 405

Sinoatrial node
Differences in responsiveness of SA and AV node to vagal stimulation, 429

Sinus node
Effect of overdrive pacing on electrically and neurologically isolated sinus node in otherwise intact dogs, 404
Electrophysiology of the canine sinus node during cardiopulmonary bypass: technique for localization and response to cold cardioplegia, 405
Sinus node dysfunction in spinal cord injury with quadriplegia, 393
Sinus node excision—a study of atrial subsidiary pacemakers—a canine model of the sick sinus syndrome, 405
Sinus node function after cardiac transplantation, 496

Smoking
Platelet activity in coronary disease, relationship to smoking and hyperlipidemia, 456

Sodium
Effect of dietary sodium and potassium content on sympathetic activity in spSHR, 478

Spinal cord injury
Sinus node dysfunction in spinal cord injury with quadriplegia, 393

Stenosis
Late results of operation for discrete subaortic stenosis, 432
Morphological-clinical correlates of myocardial fibrosis due to discrete subaortic stenosis in Newfoundland dogs, 447
Myomectomy and mitral valve replacement for idiopathic hypertrophic subaortic stenosis: five year follow-up, 424

Stimulation, cardiac
Programmed premature stimulation as a guide to antiarrhythmic therapy for malignant ventricular arrhythmia in the absence of ambient ectopy, 497

Stimulation, electrical
Results of programmed stimulation in 80 patients having a history but no electrocardiographic documentation of tachycardia, 433

Stimulation, ventricular
Anatomic and electrophysiologic correlates of ventricular tachycardia requiring left ventricular stimulation, 448
Reproducibility of electrophysiologic responses to programmed ventricular stimulation during serial drug testing in patients with recurrent ventricular tachycardia, 449

Streptokinase
Dissolution of coronary artery bypass graft thrombi by streptokinase infusion, 493
Intracoronary streptokinase in acute myocardial infarction: assessment by T1-201 scintigraphy, 493
Lysis of coronary artery thrombosis with intracoronary streptokinase in acute myocardial infarction, 493

Surgery
Comparison of techniques for intraaortic balloon insertion, 417
Computed tomography. A useful technique for follow-up of both medically and surgically treated patients with thoracic aortic dissection, 451
Effect of dopamine and dobutamine on regional blood flow, myocardial oxygen consumption and high energy phosphate compounds during cardiopulmonary bypass, 416
Enhanced myocardial preservation in animals and man with nifedipine and cardioplegia, 416
Haemodynamic effects of haematocrit reduction in patients with cyanotic congenital heart disease and secondary polycythaemia, 451
Immediate post-exercise ventriculogram: a scintigraphic tool for the pre-operative assessment of reversible myocardial asynergy, 424
Mechanism of action of the encircling endocardial ventriculotomy (EEV) for treatment of intractable ischemic ventricular tachycardia, 417
Operability of adults with left to right shunts, cyanosis, and pulmonary vascular obstruction, 424
Partial atrioventricular canal defect in adults, 466
Program on the surgical control of the hyperlipidemias (POSCH): a status report, 400
Sinus node function after cardiac transplantation, 496
Surgical therapy for right ventricular tachycardia, 497
Transluminal recanalization during evolving myocardial infarct in man, 492

Surgery, aortocoronary bypass
Bypass graft surgery for coronary artery disease: a 10-13 year follow-up study of 741 patients, 485
Changes in late coronary artery bypass grafts: the variability of their intimal atherosclerosis, 401
Clinical usefulness and feasibility of determining coronary artery bypass graft patency by contrast enhanced computed tomography during the early postoperative period, 495
Cohort analysis of secular change in mortality in patients with CAD undergoing surgical intervention, 487
Comparative effects of intermittent ischemic arrest and potassium cardioplegia on diastolic ventricular compliance in patients, 417
Coronary angiography and coronary artery bypass surgery in elderly patients, 494
Coronary bypass vs medicine: problems and guidelines in assessing mortality differences, 400
Cross-sectional ultrasonic imaging of the coronary arteries (CA's) in open chested humans; the evaluation of coronary atherosclerotic lesions (ACL) at surgery, 403
Current risk surrounding coronary bypass surgery, 400
Dissolution of coronary artery bypass graft thrombi by streptokinase infusion, 493
Electrophysiologic studies before and after aortocoronary bypass in patients with out-of-hospital ventricular fibrillation, 497
Evaluation of aortocoronary bypass graft patency status by computed tomography, 401
Factors affecting mortality after mitral valve replacement combined with coronary bypass grafting, 494
Factors influencing results during 12 years of coronary artery bypass surgery in 7,362 patients, 485
Hyperlipoproteinemia (HLP) as a significant risk factor for pulmonary embolism (PE) in coronary artery bypass (CABG) patients, 494
Improved graft patency with antiplatelet drugs in patients treated for one year following coronary bypass surgery, 494
Increase in regional myocardial perfusion post-coronary artery bypass grafting, 417
Inotropic contractile reserve: a useful predictor of increased five year postoperative survival and improved left ventricular function in patients with coronary artery disease and a depressed ejection fraction, 495
Potential role of intravenous angiography in management of cardiac surgery patients, 400
Preservation of interventricular septal function in patients having coronary artery bypass grafts without cardiopulmonary bypass, 394
Prevention of postoperative supraventricular tachyarrhythmia in coronary bypass patients, with low-dose propranolol, 431
Results of coronary bypass at least 10 years after operation in 250 patients, 485
Ten year experience with the internal mammary artery as a coronary bypass graft, 485
Total occlusion of the left main coronary artery: the CASS experience, 408

Surgery, cardiac transplantation
Accelerated coronary atherosclerosis following cardiac transplantation:

significance of hypercholesterolemia, 452
Surgery, pediatric
Collaborative study of blade atrial septostomy, 439
Complete atrioventricular canal associated with tetralogy of Fallot, 467
Conduit surgery for right ventricular and pulmonary artery continuity. Experience in both infants and older children, 467
Echocardiographic and angiocardiographic features before and after the Jatene procedure (arterial switch) for transposition of the great arteries, 431
Hemodynamic evaluation of the Fontan procedure at rest and with exercise, 432
Late results of correction for tetralogy of Fallot: a long-term, follow-up evaluation of 300 patients, 466
Late results of operation for discrete subaortic stenosis, 432
Morphometric analysis of lung biopsy tissue in candidates for Fontan-type surgical procedures, 447
Mustard's operation in the first month of life, 466
Radionuclide angiocardiographic assessment of patients following repair of transposition of the great arteries, 473
Repair of rheumatic aortic regurgitation in adolescence, 425
Rest and exercise hemodynamics after Fontan procedure, 432
Tetralogy of Fallot: 11 year experience in New England, 432
Surgery, valve
Calcification of cardiac valve bioprostheses: histologic, ultrastructural, and biochemical studies in a subcutaneous implantation model system, 440
Echocardiographic assessment of the St. Jude mitral prosthesis, 441
Experience with primary failure of porcine bioprosthetic cardiac valves, 441
Factors affecting mortality after mitral valve replacement combined with coronary bypass grafting, 494
Five year follow-up of aortic homograft monocusps used in reconstruction of the right ventricular outflow tract in infants with tetralogy of Fallot, 466
Has echocardiography any place in determining the timing of operation in aortic regurgitation? 425
Hemodynamic results following aortic valve replacement with the Hancock standard orifice bioprostheses, 440
Left ventricular function and stiffness before and after successful surgery for mitral regurgitation, 427
Long term results of tricuspid valve replacement—the problem of late thrombosis, 441
Myocyte disarray develops in papillary muscles released from normal tension after mitral valve replacement, 409
Myomectomy and mitral valve replacement for idiopathic hypertrophic subaortic stenosis: five year follow-up, 424
Noninflammatory aortic root disease: an important cause of aortic regurgitation. Echocardiographic and histopathologic correlation, 425
Open mitral commissurotomy: late follow-up of 108 patients, 425
Platelet survival time and betathromboglobulin in cardiac valve replacement, 498
Quantification of valvular regurgitation before and after medical and surgical therapy by radionuclide angiography, 498
Regurgitation of prosthetic heart valves: dependence on heart rate and cardiac output, 441
Repair of rheumatic aortic regurgitation in adolescence, 425
Right and left ventricular performance before and after correction of mitral stenosis, 424
Systolic mechanics during surgical correction of chronic mitral regurgitation, 427
Surgery versus medical therapy
Coronary bypass vs medicine: problems and guidelines in assessing mortality differences, 400
Effect of medical and surgical therapy on prognosis in patients with isolated left anterior descending coronary artery disease, 486
Unstable angina: effect of medical versus surgical therapy on survival and myocardial infarction, 486
Sympathetic nervous system
Non-uniform effects of sympathetic nerve stimulation on ventricular refractoriness in healed myocardial infarction: comparison to acute infarction, 436
Sympathetic response to exercise in patients with congestive heart failure, 395
Syncope
Electrophysiologic assessment of patients with syncope, 433
Unexplained syncope: results of therapy based on electrophysiologic studies, 433

Tachycardia
Activation mapping in sinus rhythm in patients with ventricular tachycardia-relationship to cycle length and site or origin, 497
Anatomic and electrophysiologic correlates of ventricular tachycardia requiring left ventricular stimulation, 448
Atrial tachycardia. The paroxysmal versus the permanent form, 495
Autodecremental atrial pacing for tachycardia termination-a clinical evaluation, 435
Automatic cycle length adjustment–A versatile pacemaker for tachycardia termination, 476
Benefits and risks of combined burst pacing and drug therapy of recurrent ventricular tachycardia, 476
Characterization of the onset of ectopic atrial tachycardia with A-V block, 496
Comparative effects of cycle length on ventricular refractoriness of normal and chronically infarcted myocardium, 391
Endocardial pace-mapping to localize the origin of ventricular tachycardia, 488
Fragmented electrical activity-relationship to ventricular tachycardia, 448
Initiation of atrio-ventricular nodal re-entrant tachycardia in patients with discontinuous antegrade conduction curves. Importance of a discontinuous retrograde conduction curve, 434
Lack of effectiveness of bretylium in paroxysmal sustained ventricular tachycardia, 438
Long-term effectiveness of dual-demand sequential pacing for automatic conversion and prevention of refractory reentry supraventricular tachycardia, 476
Mexiletine for resistant ventricular tachycardia: comparison with lidocaine and enhancement of efficacy by combination with quinidine, 438
Myocardial biopsy in patients with ventricular tachycardia, 499
Reproducibility of electrophysiologic responses to programmed ventricular stimulation during serial drug testing in patients with recurrent ventricular tachycardia, 449
Results of programmed stimulation in 80 patients having a history but no electrocardiographic documentation of tachycardia, 433
Significance of repetitive ventricular responses induced by atrial and ventricular pacing in patients with and without ventricular tachycardia, 448
Simultaneous operation of multiple reentrant circuits during uniform ventricular tachycardia, 391
Slow ventricular activation detected on the body surface in patients with ventricular tachycardia after myocardial infarction, 498
Successful control of the chronic form of supraventricular tachycardia with oral verapamil hydrochloride, 482
Surgical therapy for right ventricular tachycardia, 497
Two years' clinical experience with a self-searching tachycardia pacemaker, 476
Terbutaline
Effect of terbutaline on right and left ventricular function and size in obstructive lung disease, 491
Hemodynamic and metabolic effects of terbutaline in patients with severe heart failure, 491
Testosterone
Relationship between plasma testosterone and lipoprotein cholesterol, 420
Tetralogy of Fallot
Complete atrioventricular canal associated with tetralogy of Fallot, 467
Five year follow-up of aortic homograft monocusps used in reconstruction of the right ventricular outflow tract in infants with tetralogy of Fallot, 466
Late results of correction for tetralogy of Fallot: a long-term, follow-up evaluation of 300 patients, 466
Tetralogy of Fallot: 11 year experience in New England, 432
Thallium-201
Quantitative analysis of stress distribution and washout of T1-201 myocardial scintigrams: superiority over visual assessment for evaluation of coronary artery disease, 443

Thrombosis
Long term results of tricuspid valve replacement—the problem of late thrombosis, 441
Thrombus
Detection of left ventricular thrombi by radionuclide angiography, 474
Dynamic intracavitary echocardiographic patterns associated with left ventricular mural thrombi: clinical and experimental observations, 471
Embolic potential of left ventricular thrombus (LVT) detected by two-dimensional echocardiography (2DE), 471
Failure of aspirin to prevent incorporation of indium labelled platelets into cardiac thrombi in man, 455
Indium-III platelet scintigraphy and two dimensional echocardiography in the diagnosis of left ventricular thrombi, 474
Lysis of coronary artery thrombosis with intracoronary streptokinase in acute myocardial infarction, 493
Platelet thrombus formation is stenosed canine coronary arteries and their inhibition with ibuprofen, 456
Red cell involvement in platelet thrombi formed in stenosed canine coronary arteries, 456
Transluminal recanalization during evolving myocardial infarct in man, 492
Tomography
Clinical usefulness and feasibility of determining coronary artery bypass graft patency by contrast enhanced computed tomography during the early postoperative period, 495
Computed tomography. A useful technique for follow-up of both medically and surgically treated patients with thoracic aortic dissection, 451
Computerized axial tomography of the thorax: size of right pulmonary artery in right ventricular outflow tract obstruction, 458
Evaluation of aortocoronary bypass graft patency status by computed tomography, 401
Evaluation of infarcted and ischemic myocardium with 18-fluorodeoxyglucose, $^{13}NH_3$, and positron computed tomography, 481
Exercise testing of women with chest pain with and without thallium tomography, 422
Quantitation of experimental canine myocardial infarct size with technetium stannous pyrophosphate: a comparison of multipinhole and rotating slant hole emission tomography, 443
Quantitation of myocardial perfusion in man using oxygen-15 and positron tomography, 481
Transposition of great arteries
Echocardiographic and angiocardiographic features before and after the Jatene procedure (arterial switch) for transposition of the great arteries, 431
Radionuclide angiocardiographic assessment of patients following repair of transposition of the great arteries, 473
Radionuclide evaluation of RV and LV function (FX) in children-cineangiographic validation and observations in transposition of the great arteries (TGA), 458
Tricuspid atresia
Evaluation of tricuspid atresia by two-dimensional echocardiography, 479
Radionuclide assessment of left ventricular function in patients with tricuspid atresia, 431
Tricuspid regurgitation
Echocardiographic evaluation of tricuspid annulus size and function in normal and in tricuspid regurgitation, 412
Tricuspid valve
Echocardiographic evaluation of tricuspid annulus size and function in normal and in tricuspid regurgitation, 412

Vagal stimulation
Differences in responsiveness of SA and AV node to vagal stimulation, 429
Valve disease
Quantitation of left ventricular output in patients with and without left-sided valvular regurgitation using equilibrium radionuclide ventriculography, 454
Valve prostheses
Calcification of cardiac valve bioprostheses: histologic, ultrastructural, and biochemical studies in a subcutaneous implantation model system, 440
Echocardiographic assessment of the St. Jude mitral prosthesis, 441
Experience with primary failure of porcine bioprosthetic cardiac valves, 441
Hemodynamic results following aortic valve replacement with the Hancock standard orifice bioprostheses, 440
Regurgitation of prosthetic heart valves: dependence on heart rate and cardiac output, 441
Valve regurgitation
Quantification of valvular regurgitation before and after medical and surgical therapy by radionuclide angiography, 498
Vasodilators
Maximal improvement in ventricular performance during rest and exercise in chronic severe cardiac failure by combined inotropic and vasodilator therapy compared to either modality alone, 390
Ventricle, left
Accuracy of M-mode echo measurements of the left ventricle, 453
Divergent left ventricular response to exercise in children with left ventricular pressure or volume overload, 446
Ventricle, right
Hemodynamic effects of hydralazine in patients with isolated right ventricular failure, 390
Mechanism of low output in experimental right ventricular infarction, 437
Right ventricular cardiomyopathy presenting with recurrent ventricular tachycardia, 402
Right ventricular infarction: clinical course and follow-up, 458
Serial evaluation of right ventricular function after right ventricular infarction, 458

Ventricular arrhythmias
Anatomic and electrophysiologic correlates of ventricular tachycardia requiring left ventricular stimulation, 448
Calcium antagonists: their effectiveness in decreasing the occurence of ventricular fibrillation and reducing infarct size after a coronary artery occlusion, 443
Effect of prostacyclin on ventricular arrhythmias and intracardiac conduction in myocardial ischemia, 437
Electrophysiologic studies before and after implantation of the automatic defibrillator, 397
Fragmented electrical activity-relationship to ventricular tachycardia, 448
Improved survival in sudden death/ventricular tachycardia patients with therapeutic antiarrhythmic drug levels, 438
Lack of effectiveness of bretylium in paroxysmal sustained ventricular tachycardia, 438
Mechanism of action of the encircling endocardial ventriculotomy (EEV) for treatment of intractable ischemic ventricular tachycardia, 417
Mexiletine for resistant ventricular tachycardia: comparison with lidocaine and enhancement of efficacy by combination with quinidine, 438
Predictive value of programmed electrical stimulation in patients with sudden death or recurrent ventricular tachycardia, 397
Prevalence and significance of ventricular tachycardia in the late hospital phase of myocardial infarction, 397
Prognostic value of ventricular arrhythmias, 397
Refractoriness of premature and nonpremature beats in the human ventricle, 448
Right ventricular cardiomyopathy presenting with recurrent ventricular tachycardia, 402
Ventricular contractility
Limitations of histological morphometric analysis in predicting drug preservation of contractility in cardiomyopathy, 460
Ventricular dimensions
Alterations in left ventricular geometry during inspiration in the conscious dog, 411
Ventricular fibrillation
Demonstation of exercise-induced ischemia without angina in patients who recover from out-of-hospital ventricular fibrillation, 445
Electrophysiologic studies before and after aortocoronary bypass in patients with out-of-hospital ventricular fibrillation, 497
Low energy versus high energy defibrillation in the treatment of out-of-hospital ventricular fibrillation. A preliminary report, 398
Protection against ventricular fibrillation by calcium antagonists, 438
Radionuclide ventriculography following resuscitation from out-of-hospital ventricular fibrillation, 474
Repetitive extrasystole as an index of vulnerability to ventricular fibrillation during myocardial ischemia, 391

Time course of vulnerability to reperfusion-induced ventricular fibrillation, 461
Ventricular fibrillation threshold during propranolol withdrawal, 431
Ventricular function
Abnormal mitral annular contraction in cardiomyopathies and correlation with left ventricular function, 409
Alterations in left ventricular geometry during inspiration in the conscious dog, 411
Does LV function reach a steady state during sustained exercise? 468
Effect of prolonged prazosin treatment on the hemodynamics and cardiac electrolytes and Na^+-K^+ATPase in dogs with chronic aortic stenosis, 426
Effect of rate-dependent left bundle branch block on left ventricular ejection fraction and regional wall motion, 415
Effect of terbutaline on right and left ventricular function and size in obstructive lung disease, 491
Effect of verapamil on exercise-induced regional myocardial dysfunction in conscious dogs, 416
Effect of verapamil on left ventricular function: randomized, placebo-controlled study, 406
Effect of verapamil on the diastolic mechanics of the left ventricle, 411
Effects of bedrest deconditioning on exercise ventricular function in middle-aged men, 477
Effects of moderate and high dose propranolol on ventricular function in patients with coronary artery disease, 430
Effects of verapamil and nifedipine on left ventricular function in patients with Prinzmetal's variant angina, 394
Errors of estimation of functional capacity in cardiac patients, 415
Evaluation of left ventricular function at rest and during exercise by transesophageal echocardiography in aortic insufficiency, 412
Hypothermic retroperfusion treatment of acute myocardial ischemia: effects on cardiac function and infarct size, 436
Inferior vena caval ultrasonagraphy: its use in the assessment of right heart function, 453
Inotropic contractile reserve: a useful predictor of increased five year postoperative survival and improved left ventricular function in patients with coronary artery disease and a depressed ejection fraction, 495
Is isovolumic relaxation impaired in secondary hypertrophy? 395
Left ventricular contractile failure following hypothermic ischemic arrest: protection by coronary artery washout, 414
Left ventricular dysfunction in patients with mitral regurgitation, 410
Left ventricular ejection rate during the first third of systole in patients with aortic insufficiency, 410
Left ventricular function and stiffness before and after successful surgery for mitral regurgitation, 427
Left ventricular function before and after successful catheter dilatation of critical coronary stenoses, 396
Left ventricular response to exercise after anterior myocardial infarction: differences between patients with single and multivessel coronary artery disease, 408
Long term effect of oral amrinone in heart failure: improvement in exercise performance despite declining left ventricular pump function, 428
Long-term effects of verapamil on left ventricular diastolic filling in patients with hypertrophic cardiomyopathy, 409
Mechanisms of load independence of relaxation during hypoxia in mammalian cardiac muscle, 410
Noninvasive determination of the endsystolic pressure volume relation in patients with aortic regurgitation, 427
Oral verapamil vs propranolol in coronary artery disease: evaluation of left ventricular function by exercise radionuclide ventriculography, 463
Potential value of oral β_2 adrenoceptor agonists in left ventricular failure, 427
Prognostic value of ventricular arrhythmias, 397
Quantification of myocardial function during transient changes in regional coronary blood flow, 445
Quantification of pericardial influences on diastolic filling of the left ventricle, 411
Radionuclide assessment of left ventricular function in patients with tricuspid atresia, 431
Radionuclide evaluation of RV and LV function (FX) in children-cineangiographic validation and observations in transposition of the great arteries (TGA), 458
Reversible segmental contraction abnormalities during exercise induced coronary artery spasm and their effect on global left ventricular function, 451
Right and left ventricular performance before and after correction of mitral stenosis, 424
Serial evaluation of right ventricular function after right ventricular infarction, 458
Serial radionuclide assessment of doxorubicin cardiotoxicity in cancer patients with abnormal baseline resting left ventricular performance, 474
Systolic load dependency of left ventricular relaxation is influenced by beta adrenergic tone and abnormal synchrony, 410
Systolic mechanics during surgical correction of chronic mitral regurgitation, 427
Ventricular outflow tract
Five year follow-up of aortic homograft monocusps used in reconstruction of the right ventricular outflow tract in infants with tetralogy of Fallot, 466
Ventricular septal defect
Hemodynamic effects of hydralazine in infants with large ventricular septal defect, 439
Reciprocal development of 4th and 6th aortic arches in pulmonary atresia with ventricular septal defect, 447
Role of two-dimensional echocardiography in evaluation of patients with post myocardial infarction ventricular septal defect, 461
Ventricular volumes
Automated method for left ventricular volume measurement from the cineventriculography with minimal doses of contrast medium, 394
Changes in left ventricular volumes during upright exercise in patients with coronary artery disease, 468
Correlation of cineangiography and blood pool scan for measurement of left ventricular volume in human cadaver hearts, 455
Radionuclide determination of left ventricular volume: comparison of counts-based and geometric methods, 454
Shifts in left and right ventricular diastolic pressure-volume curves due to pericardial effusion and tamponade, 411
Simultaneous contrast two-dimensional echocardiography and contrast ventriculography: discrepancies in left ventricular volume, 453
Two dimensional echocardiographic estimation of left ventricular volume in small newborn lamb hearts, 479
Ventricular wall motion
Anterior transmural myocardial infarction (AMI). Analysis of regional wall motion during the early hours with and without total coronary occlusion, 459
Effects of coupling intervals on contraction patterns of premature beats derived by computer assisted two-dimensional echocardiography, 471
Heterogeneity of segmental left ventricular wall thickening and excursion in two-dimensional echocardiograms of normal humans, 452
Immediate post-exercise ventriculogram: a scintigraphic tool for the pre-operative assessment of reversible myocardial asynergy, 424
One minute multiple gated equilibrium scintigraphy for assessment of left ventricular ejection fraction and segmental wall motion: validation with state of the art instrumentation and optimized space-time smoothing, 454
Reversible segmental contraction abnormalities during exercise induced coronary artery spasm and their effect on global left ventricular function, 451
Ventriculography
Immediate post-exercise ventriculogram: a scintigraphic tool for the pre-operative assessment of reversible myocardial asynergy, 424
Simultaneous contrast two-dimensional echocardiography and contrast ventriculography: discrepancies in left ventricular volume, 453
Ventriculography, radionuclide
Clinical utility of cold pressor radionuclide ventriculography in coronary artery disease, 444
Oral verapamil vs propranolol in coronary artery disease: evaluation of left ventricular function by exercise radionuclide ventriculography, 463
Quantitation of left ventricular output in patients with and without left-sided valvular regurgitation using equilibrium radionuclide ventriculography, 454
Radionuclide evaluation of RV and LV function (FX) in children-cineangiographic validation

and observations in transposition of the great arteries (TGA), 458
Radionuclide ventriculography following resuscitation from out-of-hospital ventricular fibrillation, 474

Verapamil
Antiplatelet effects of verapamil in man, 399
Clinical utility of plasma verapamil levels in patients with hypertrophic cardiomyopathy, 407
Comparison of verapamil and nifedipine in patients with Prinzmetal's variant angina pectoris, 398
Concentration dependent heart rate suppression with verapamil, 406
Contrasting effects of procainamide and verapamil on intraventricular conduction and reentry, 449
Differing effects of verapamil relative to varying levels of myocardial performance in patients with coronary artery disease, 406
Double-blind, randomized, placebo-controlled comparison of propranolol and verapamil in patients with stable, exertional angina pectoris, 463
Effect of verapamil on exercise-induced regional myocardial dysfunction in conscious dogs, 416
Effect of verapamil on left ventricular function: randomized, placebo-controlled study, 406
Effect of verapamil on the diastolic mechanics of the left ventricle, 411
Effects of verapamil and nifedipine on left ventricular function in patients with Prinzmetal's variant angina, 394
Long-term effects of verapamil on left ventricular diastolic filling in patients with hypertrophic cardiomyopathy, 409
Nifedipine but not verapamil has age-independent effects on cardiac repolarization, 475
Oral verapamil vs propranolol in coronary artery disease: evaluation of left ventricular function by exercise radionuclide ventriculography, 463
Protective effects of verapamil and hydralazine on the cardiomyopathy of the Syrian hamster, 460
Relationship between pharmacodynamics and myocardial concentration of verapamil, 406
Safety and efficacy of short and long term verapamil therapy in children with tachycardia, 439
Successful control of the chronic form of supraventricular tachycardia with oral verapamil hydrochloride, 482
Verapamil in the treatment of Prinzmetal's variant angina: a long-term, double-blind, randomized trial, 399

Wolff-Parkinson-White syndrome
Disopyramide phosphate in Wolff-Parkinson-White syndrome, 495

X-irradiation
Reduction of myocardial fibrosis by early methyl prednisone or ibuprofen administration in experimental radiation induced heart disease, 402

Pfizer Laboratories
invites you to attend
an Educational Symposium:*

Nifedipine in Ischemic Heart Disease: The International Experience

Chairman:
Dennis Krikler, M.D., F.A.C.C.
Consultant Cardiologist
Royal Postgraduate Medical School
Hammersmith Hospital, London, England

The symposium immediately follows the 30th Annual Scientific Session of the American College of Cardiology and will be held in:

The Imperial Ballroom of
The San Francisco Hilton Hotel
333 O'Farrell St., San Francisco, California

March 19, 1981
1:30-5:30 P.M.

If you would like to attend the symposium and have not yet registered, please do so at the Pfizer booths #2004, 2005 and 1101 at Brooks Hall during the American College of Cardiology Session.

*Science & Medicine is assisting in the organization of the symposium under an educational grant from Pfizer Laboratories.

Nifedipine in the Management of Ischemic Heart Disease: The European Experience

MODERATOR: **Eugene Braunwald, M.D., F.A.C.C.**
Hersey Professor of the Theory and Practice of Medicine
Harvard Medical School

TOPICS:

SUMMARY STATEMENT: **Dennis Krikler, M.D., F.A.C.C.**

Another Step Forward In Electrocardiography... 12 Simultaneous Leads

Marquette Electronics' philosophy is, and always has been, to make basic contributions in the field of electrocardiography.

Thus when we decided to write our new ECG computer analysis program two years ago, we were determined to find a way to make this program not just better, but much better.

Of course, when we introduced three channel telephone transmission in 1966, computer programs improved considerably by virtue of the ability to analyze three leads at the same time.

Then in 1978, we developed a method to acquire and transmit to a computer all twelve leads digitally and **simultaneously**, without adding noise or distortion of any kind.

This development made it possible to derive much more accurate and reliable measurements of the ECG waveforms. And, with these measurements the computer program can provide analyses with greatly improved sensitivity and specificity.

We have now installed several ECG Processing Systems using the new Marquette Analysis Program. Initial reports indicate the program is producing an interpretation with a much higher level of physician agreement.

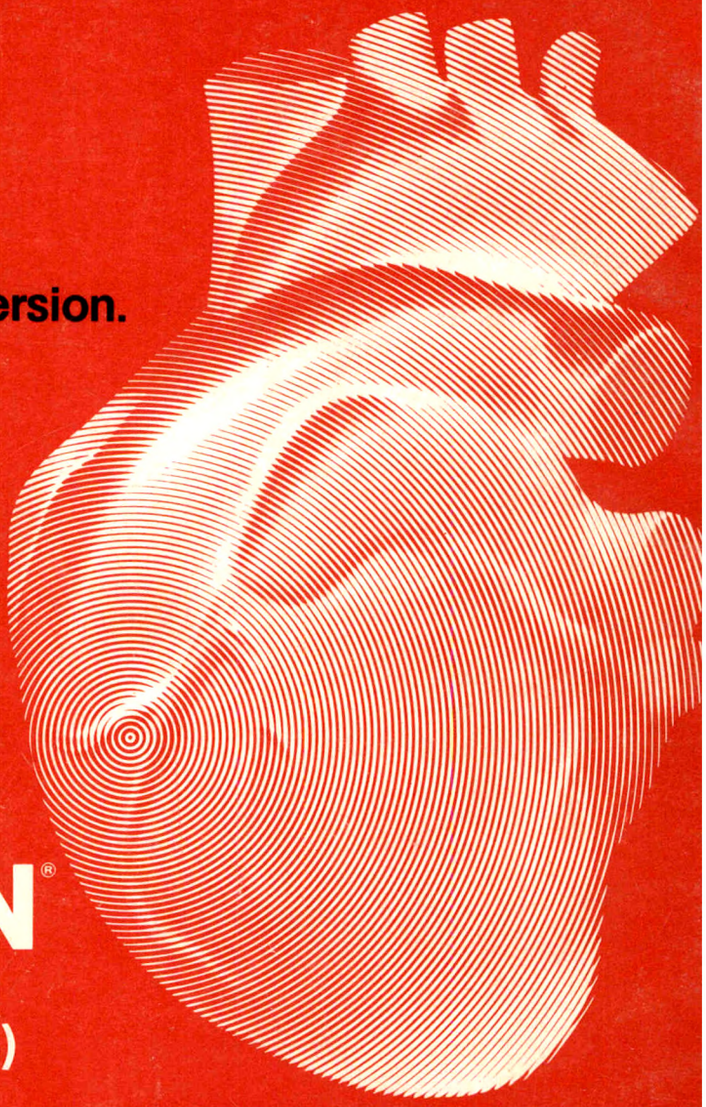
The Pacekeeper

For ventricular arrhythmias.
For atrial arrhythmias.
For smooth, trouble-free conversion.
For steady maintenance.



CARDIOQUIN®
TABLETS
(quinidine polygalacturonate)

- ☐ Greater GI tolerance than with quinidine sulfate
- ☐ Full quinidine cardiodynamics
- ☐ Convenient b.i.d. or t.i.d. dosage for most patients

CARDIOQUIN Tablets (quinidine polygalacturonate) are indicated in the treatment of a broad range of cardiac arrhythmias (see Brief Summary). After conversion to normal sinus rhythm—whether with CARDIOQUIN Tablets or electroconversion—only low b.i.d. or t.i.d. dosage of this unique polygalacturonate salt of quinidine is required for maintenance in most cases. The polygalacturonic acid serves as a buffering moiety. It protects the mucosa of the stomach and permits dependable absorption of the quinidine.*

*Aviado, D. M., Krantz and Carr's Pharmacologic Principles of Medical Practice, ed. 8, Baltimore, Williams and Wilkins Co., 1972, p. 456.

BRIEF SUMMARY—INDICATIONS: CARDIOQUIN Tablets (quinidine polygalacturonate) are indicated in the treatment of: premature atrial and ventricular contractions; paroxysmal atrial tachycardia; paroxysmal AV junctional rhythm; atrial flutter; paroxysmal atrial fibrillation; established atrial fibrillation when therapy is appropriate; paroxysmal ventricular tachycardia when not associated with complete heart-block; maintenance therapy after electrical conversion of atrial fibrillation and/or flutter. CONTRAINDICATIONS: Aberrant impulses and abnormal rhythms due to escape mechanisms should not be treated with quinidine. WARNING: In the treatment of atrial flutter reversion to sinus rhythm may be preceded by a progressive reduction in the degree of AV block to a 1:1 ratio and resulting extremely rapid ventricular rate. COMPOSITION: Each CARDIOQUIN Tablet (quinidine polygalacturonate 275 mg.) is equivalent in quinidine content to 3 grains quinidine sulfate. DOSAGE AND ADMINISTRATION: Dosage must be adjusted to individual needs, both for conversion and maintenance. An initial dose of 1 to 3 tablets may be used to terminate arrhythmias, and may be repeated in 3-4 hours. If normal sinus rhythm is not restored after 3 or 4 equal doses, the dose may be increased by ½ to 1 tablet (137.5 to 275 mg.) and administered three to four times before any further dosage increase. For maintenance, one tablet may be used two to three times a day; generally one tablet morning and night will be adequate. SUPPLIED: Uncoated, scored tablets in bottles of 100.

ANSWERS ABOUT ALDOMET® (METHYLDOPA|MSD)

Will an antihypertensive generally allow a normal cardiovascular response to exercise?

Cardiac output and blood pressure normally increase with increasing physical activity. ALDOMET does not significantly impair normal fluctuations of blood pressure during exercise.[1,2]

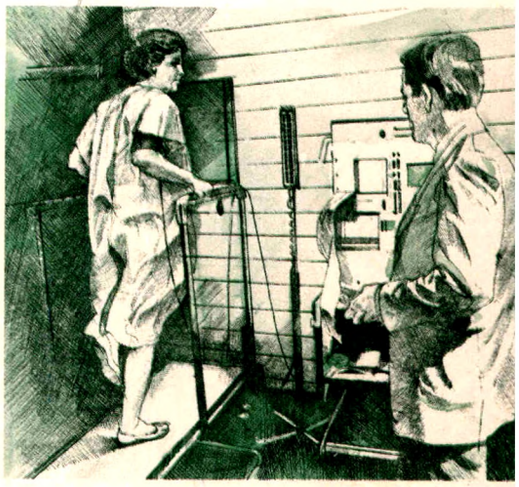
In a recent study of hypertensive patients whose cardiovascular response to exercise was evaluated before and during methyldopa therapy, "...methyldopa significantly reduced the rise in systolic pressure during the build-up ($P<0.01$) and subjective maximal stages ($P<0.05$) as well as at all phases of recovery ($P<0.01$)." Moreover, "The total duration of exercise (an index of work capacity) was unchanged with...methyldopa."[3]

Such findings can be of importance to active hypertensive patients such as the athletic individual or the person whose work requires substantial physical effort. For these and many other hypertensive patients, ALDOMET represents a logical therapeutic choice.

With ALDOMET, exercise hypotension rarely occurs. Sedation, usually transient, may occur during the initial period of therapy or whenever the dose is increased. Headache, asthenia, or weakness may be noted as early and transient symptoms.

ALDOMET® offers many (METHYLDOPA|MSD) other important features:

- Highly effective in all degrees of hypertension.
- Existing cardiac output is usually maintained.
- Renal blood flow is usually maintained.
- Has documented long-term efficacy.
- Significant adverse effects have been infrequent and the agent is usually well tolerated.



ALDOMET is contraindicated in active hepatic disease, hypersensitivity to the drug, and if prev methyldopa therapy has been associated with l disorders. It is important to recognize that a pos Coombs test, hemolytic anemia, and liver disor may occur with methyldopa therapy. The rare occurrences of hemolytic anemia or liver disord could lead to potentially fatal complications unl properly recognized and managed.

For hypertension—

ALDOMET
(METHYLDOPA|MS

The most prescribed nondiuretic antihypertensi in the U.S. today

Contraindications: Active hepatic disease, such as acute hepatitis and active cirrhosis; if previous methyldopa therapy has been associated with liver disorders (see Warnings); hypersensitivity.

Warnings: It is important to recognize that a positive Coombs test, hemolytic anemia, and liver disorders may occur with methyldopa therapy. The rare occurrences of hemolytic anemia or liver disorders could lead to potentially fatal complications unless properly recognized and managed. Read this section carefully to understand these reactions.

With prolonged methyldopa therapy, 10% to 20% of patients develop a positive direct Coombs test, usually between 6 and 12 months of therapy. Lowest incidence is at daily dosage of 1 g or less. This on rare occasions may be associated with hemolytic anemia, which could lead to potentially fatal complications. One cannot predict which patients with a positive direct Coombs test may develop hemolytic anemia. Prior existence or development of a positive direct Coombs test is not in itself a contraindication to use of methyldopa. If a positive Coombs test develops during methyldopa therapy, determine whether hemolytic anemia exists and whether the positive Coombs test may be a problem. For example, in addition to a positive direct Coombs test there is less often a positive indirect Coombs test which may interfere with cross matching of blood.

At the start of methyldopa therapy, it is desirable to do a blood count (hematocrit, hemoglobin, or red cell count) for a baseline or to establish whether there is anemia. Periodic blood counts should be done during therapy to detect hemolytic anemia. It may be useful to do a direct Coombs test before therapy and at 6 and 12 months after the start of therapy. If Coombs-positive hemolytic anemia occurs, the cause may be methyldopa and the drug should be discontinued. Usually the anemia remits promptly. If not, corticosteroids may be given and other causes of anemia should be considered. If the hemolytic anemia is related to methyldopa, the drug should not be reinstituted. When methyldopa causes Coombs positivity alone or with hemolytic anemia, the red cell is usually coated with gamma globulin of the IgG (gamma G) class only. The positive Coombs test may not revert to normal until weeks to months after methyldopa is stopped.

Should the need for transfusion arise in a patient receiving methyldopa, both a direct and an indirect Coombs test should be performed on his blood. In the absence of hemolytic anemia, usually only the direct Coombs test will be positive. A positive direct Coombs test alone will not interfere with typing or cross matching. If the indirect Coombs test is also positive, problems may arise in the major cross match and the assistance of a hematologist or transfusion expert will be needed.

Fever has occurred within first 3 weeks of therapy, occasionally with eosinophilia or abnormalities in liver function tests, such as serum alkaline phosphatase, serum transaminases (SGOT, SGPT), bilirubin, cephalin cholesterol flocculation, prothrombin time, and bromsulphalein retention. Jaundice, with or without fever, may occur, with onset usually in the first 2 to 3 months of therapy. In some patients the findings are consistent with those of cholestasis. Rarely fatal hepatic necrosis has been reported. These hepatic changes may represent hypersensitivity reactions; periodic determination of hepatic function should be done particularly during the first 6 to 12 weeks of therapy or whenever an unexplained fever occurs. If fever and abnormalities in liver function tests or jaundice appear, stop therapy with methyldopa. If caused by methyldopa, the temperature and abnormalities in liver function characteristically have reverted to normal when the drug was discontinued. Methyldopa should not be reinstituted in such patients.

Rarely, a reversible reduction of the white blood cell count with primary effect on granulocytes has been seen. Reversible thrombocytopenia has occurred rarely. When used with other antihypertensive drugs, potentiation of antihypertensive effect may occur. Patients should be followed carefully to detect side reactions or unusual manifestations of drug idiosyncrasy.

Pregnancy and Nursing: Use of any drug in women who are or may become pregnant or intend to nurse requires that anticipated benefits be weighed against possible risks; possibility of fetal injury or injury to a nursing infant cannot be excluded. Methyldopa crosses the placental barrier, appears in cord blood, and appears in breast milk.

Precautions: Should be used with caution in patients with history of previous liver disease or dysfunction (see Warnings). May interfere with measurement of: urinary uric acid by the phosphotungstate method, serum creatinine by the alkaline picrate method, and SGOT by colorimetric methods. Since methyldopa causes fluorescence in urine samples at the same wavelengths as catecholamines, falsely high levels of urinary catecholamines may be reported. This will interfere with the diagnosis of pheochromocytoma. It is important to recognize this phenomenon before a patient with a possible pheochromocytoma is subjected to surgery. Methyldopa is not recommended for patients with pheochromocytoma. Urine exposed to air after voiding may darken because of breakdown of methyldopa or its metabolites.

Stop drug if involuntary choreoathetotic movements occur in patients with severe bilateral cerebrovascular disease. Patients may require reduced
anesthetics; hypotension occurring durir
thesia usually can be controlled with vasop
Hypertension has recurred after dialysis in
on methyldopa because the drug is remove

An Investment in Nuclear Diagnostic Confidence

Developed in conjunction with clinical cardiologists, Siemens' comprehensive selection of cardiac performance programs satisfy your demanding diagnostic requirements by providing unprecedented reproducibility and confidence in quantitative analysis.

Current clinical nuclear cardiology programs include:

- PHASE AND AMPLITUDE ANALYSIS OF VENTRICULAR FUNCTION
- EXTENDED CARDIAC ACQUISITION FOR WALL MOTION AND LEFT VENTRICULAR EJECTION FRACTION
- AUTOMATIC WALL DETECTION TO DEFINE LEFT VENTRICLE AND CALCULATING THE EJECTION FRACTION
- CARDIAC SHUNT DETECTION AND QUANTITATION OF QP AND QS RATIO
- FIRST TRANSIT CARDIAC STUDIES

Well designed, and clinically tested, these cardiac programs utilize advanced software techniques to provide pertinent and reproducible results for improved diagnostic information and patient management.

Each program offers computerized nuclear imaging with a high degree of flexibility to satisfy your individual data acquisition, processing and presentation requirements.

Additional clinical programs already in development will offer an even greater range of diagnostic possibilities.

Furthermore, since nuclear cardiology techniques are non-invasive, you can select this important diagnostic modality in clinical situations and environments previously unattainable or considered high risk.

Contact your Siemens representative for details and/or a demonstration of these most recent advances in nuclear cardiology.

In Hypertension*...When You Need to Conserve K^+

Every Step of the Way

Each capsule contains 50 mg. of Dyrenium® (brand of triamterene) and 25 mg. of hydrochlorothiazide.

†Step 1 usually consists of an initial phase (a diuretic alone), a titration phase (dosage adjustment and/or addition of a K^+ supplement or K^+-sparing agent and a maintenance phase (a diuretic alone or in combination with a K^+ supplement or K^+-sparing agent).

Serum K^+ and BUN should be checked periodically (see Warnings).

Before prescribing, see complete prescribing information in SK&F Co. literature or *PDR*. A brief summary follows:

WARNING
This drug is not indicated for initial therapy of edema or hypertension. Edema or hypertension requires therapy titrated to the individual. If this combination represents the dosage so determined, its use may be more convenient in patient management. Treatment of hypertension and edema is not static, but must be reevaluated as conditions in each patient warrant.

Contraindications: Further use in anuria, progressive renal or hepatic dysfunction, hyperkalemia. Pre-existing elevated serum potassium. Hypersensitivity to either component or other sulfonamide-derived drugs.

Warnings: Do not use potassium supplements, dietary or otherwise, unless hypokalemia develops or dietary intake of potassium is markedly impaired. If supplementary potassium is needed, potassium tablets should not be used. Hyperkalemia can occur, and has been associated with cardiac irregularities. It is more likely in the severely ill, with urine volume less than one liter/day, the elderly and diabetics with suspected or confirmed renal insufficiency. Periodically, serum K^+ levels should be determined. If hyperkalemia develops, substitute a thiazide alone, restrict K^+ intake. **Associated widened QRS complex or arrhythmia requires prompt additional therapy.** Thiazides cross the placental barrier and appear in cord blood. Use in pregnancy requires weighing anticipated benefits against possible hazards, including fetal or neonatal jaundice, thrombocytopenia, other adverse reactions seen in adults. Thiazides appear and triamterene may appear in breast milk. If their use is essential, the patient should stop nursing. Adequate information on use in children is not available. Sensitivity reactions may occur in patients with or without a history of allergy or bronchial asthma. Possible exacerbation or activation of systemic lupus erythematosus has been reported with thiazide diuretics.

Precautions: Do periodic serum electrolyte determinations (particularly important in patients vomiting excessively or receiving parenteral fluids). Periodic BUN and serum creatinine determinations should be made, especially in the elderly, diabetics or those with suspected or confirmed renal insufficiency. Watch for signs of impending coma in severe liver disease. If spironolactone is used concomitantly, determine serum K^+ frequently; both can cause K^+ retention and elevated serum K^+. Two deaths have been reported with such concomitant therapy (in one, recommended dosage was exceeded, in the other serum electrolytes were not properly monitored). Observe regularly for possible blood dyscrasias, liver damage, other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving triamterene, and leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with thiazides. Triamterene is a weak folic acid antagonist. Do periodic blood studies in cirrhotics with splenomegaly. Antihypertensive effect may be enhanced in postsympathectomy patients. Use cautiously in surgical patients. The following may occur: transient elevated BUN or creatinine or both, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), hyperuricemia and gout, digitalis intoxication (in hypokalemia), decreasing alkali reserve with possible metabolic acidosis. 'Dyazide' interferes with fluorescent measurement of quinidine. Hypokalemia, although uncommon, has been reported. Corrective measures should be instituted cautiously and serum potassium levels determined. Discontinue corrective measures and 'Dyazide' should laboratory values reveal elevated serum potassium. Chloride deficit may occur as well as dilutional hyponatremia. Serum PBI levels may decrease without signs of thyroid disturbance. Calcium excretion is decreased by thiazides. 'Dyazide' should be withdrawn before conducting tests for parathyroid function.

Diuretics reduce renal clearance of lithium and increase the risk of lithium toxicity.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis, rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting, diarrhea, constipation, other gastrointestinal disturbances. Necrotizing vasculitis, paresthesias, icterus, pancreatitis, xanthopsia and, rarely, allergic pneumonitis have occurred with thiazides alone. Triamterene has been found in renal stones in association with other usual calculus components.

Supplied: Bottles of 1000 capsules; Single Unit Packages (unit-dose) of 100 (intended for institutional use only); in Patient-Pak™ unit-of-use bottles of 100.

The original dipyridamole.

Persantine®
(dipyridamole)

INDICATIONS—Based on a review of this drug by the National Academy of Science-National Research Council and /or other information, FDA has classified the indication as follows:

"Possibly" effective: For long-term therapy of chronic angina pectoris. Prolonged therapy may reduce the frequency or eliminate anginal episodes, improve exercise tolerance, and reduce nitroglycerin requirements. The drug is not intended to abort the acute anginal attack.

Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS—No specific contraindications are known.

PRECAUTIONS—Since excessive doses can produce peripheral vasodilation, the drug should be used cautiously in patients with hypotension. Persantine tablets, 25 mg, contain FD&C Yellow No. 5 (tartrazine) which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. The incidence of sensitivity is generally low, but frequently seen in patients with aspirin hypersensitivity.

ADVERSE REACTIONS— Adverse reactions are minimal and transient at recommended dosages. Instances of headache, dizziness, nausea, flushing, weakness or syncope, mild gastrointestinal distress and skin rash have been noted during therapy. Rare cases of what appeared to be an aggravation of angina pectoris have been reported, usually at the initiation of therapy. On those uncommon occasions when adverse reactions have been persistent or intolerable, withdrawal of medication has been followed promptly by cessation of undesirable symptoms.

DOSAGE AND ADMINISTRATION—The recommended dosage is 50 mg three times a day, taken at least one hour before meals. In some cases higher doses may be necessary but a significantly increased incidence of side effects is associated with increased dosage. Clinical response may not be evident before the second or third month of continuous therapy.

Tablets of 25 mg and 75 mg

For patients who need K^+Cl^- one sparkles bright:

KLORVESS® EFFERVESCENT GRANULES offer SPARKLING FAST DISSOLUTION

Each packet (2.8 g) provides 20 mEq each of potassium and chloride supplied by potassium chloride 1.125 g, potassium bicarbonate 0.5 g, and L-lysine monohydrochloride 0.913 g.

- **ready in *seconds* instead of minutes —fast dissolution so unique it's patented***
- **pleasant citrus flavor**
- **each packet delivers 20 mEq of potassium and chloride**
- **easily carried in patient's pocket or purse**
- **can be mixed with water or other liquid for pleasant daily dosage**
- **sugar, sodium, carbohydrate and dye free**

Give your patients the KLORVESS sparkle

26790 A

Give your patients the KLORVESS® sparkle

Klorvess® Effervescent Granules and Klorvess® (potassium chloride) 10% Liquid

Brief summary of prescribing information

DESCRIPTION: *Klorvess Effervescent Granules:* Each packet (2.8 g) contains 20 mEq each of potassium and chloride supplied by potassium chloride 1.125 g, potassium bicarbonate 0.5 g, L-lysine monohydrochloride 0.913 g in a sodium-, sugar- and carbohydrate-free effervescent formulation. Dissolution of the packet contents in water provides the potassium and chloride available for oral ingestion as potassium chloride, potassium bicarbonate, potassium citrate and L-lysine monohydrochloride.

Klorvess (potassium chloride) 10% Liquid: Each tablespoonful (15 ml) contains 20 mEq of potassium chloride (provided by potassium chloride 1.5 g) in a palatable, cherry-with-pit flavored vehicle, alcohol 1%.

INDICATIONS: For the prevention and treatment of potassium depletion and hypokalemic-hypochloremic alkalosis. Deficits of body potassium and chloride can occur as a consequence of therapy with potent diuretic agents and adrenal corticosteroids.

CONTRAINDICATIONS: Severe renal impairment characterized by azotemia or oliguria, untreated Addison's disease, Familial Periodic Paralysis, acute dehydration, heat cramps, patients receiving aldosterone-inhibiting or potassium-sparing diuretic agents, or hyperkalemia from any cause.

PRECAUTIONS: In response to a rise in the concentration of body potassium, renal excretion of the ion is increased. In the presence of normal renal function and hydration, it is difficult to produce potassium intoxication by oral potassium salt supplements. Since the extent of potassium deficiency cannot be accurately determined, it is prudent to proceed cautiously in undertaking potassium replacement. Periodic evaluations of the patient's clinical status, serum electrolytes and the EKG should be carried out when replacement therapy is undertaken. This is particularly important in patients with cardiac disease and those patients receiving digitalis. High serum concentrations of potassium may cause death through cardiac depression, arrhythmia or cardiac arrest. To minimize gastrointestinal irritation associated with potassium chloride preparations, patients should dissolve the packet contents of *Klorvess Effervescent Granules* in 3 to 4 ounces of cold water, fruit juice or other liquid or dilute each tablespoonful of *Klorvess (potassium chloride) 10% Liquid* in 3 to 4 ounces of cold water. Both of these solutions should be ingested slowly with or immediately after meals.

ADVERSE REACTIONS: Abdominal discomfort, diarrhea, nausea and vomiting may occur with the use of potassium salts. The symptoms and signs of potassium intoxication include paresthesias, heaviness, muscle weakness and flaccid paralysis of the extremities. Potassium intoxication can produce listlessness, mental confusion, a fall in blood pressure, shock, cardiac arrhythmias, heart block and cardiac arrest. The EKG picture of hyperkalemia is characterized by the early appearance of tall, peaked T waves. The R wave is decreased in amplitude and the S wave deepens; the QRS complex widens progressively. The P wave widens and decreases in amplitude until it disappears. Occasionally, an apparent elevation of the RS-T junction and a cove plane RS-T segment and T wave will be noted in AVL.

DOSAGE AND ADMINISTRATION: *Klorvess Effervescent Granules:* Adults—One packet completely dissolved 2 to 4 times daily depending upon the requirements of the patient.

Klorvess (potassium chloride) 10% Liquid: Adults—One tablespoonful (15 ml) completely diluted in cold water 2 to 4 times daily depending upon the requirements of the patient.

Both of these solutions should be ingested slowly with meals or immediately after eating.

OVERDOSAGE: Potassium intoxication may result from overdosage of potassium or from therapeutic dosage in conditions stated under "Contraindications." Hyperkalemia, when detected, must be treated immediately because lethal levels can be reached in a few hours. In digitalized patients too rapid a lowering of plasma potassium concentration can cause digitalis toxicity.

HOW SUPPLIED: *Klorvess Effervescent Granules*—packages of 30 packets (2.8 g each). *Klorvess (potassium chloride) 10% Liquid* (dark red)—as a cherry-with-pit flavored liquid in pint and gallon bottles. Klorvess Effervescent Granules and Liquid are also available in institutional packaging as follows: *Klorvess Effervescent Granules*—packages of 1000 packets; *Klorvess Liquid*—36 (3 x 12) x 4 oz Unit-of-Use bottles and 100 (4 x 25) x 15 ml Unit-Dose bottles.

New evidence is in:

Treatment of mild hypertension can save lives

Even among patients with DBP in the low 90s systematic therapy significantly reduced mortality:

- Of nearly 11,000 hypertensives identified by the Hypertensio Detection and Follow-up Program, slightly more than 70% ha mild hypertension (DBP 90-104 mm. Hg).[1]
- Half were given systematic and aggressive care in HDFP cer ters; half were referred to customary sources of medical care.
- After 5 years, HDFP found that effective treatment of mild hypertension may reduce premature deaths by 20%.[1]
- As part of HDFP's systematic treatment and follow-up program, the primary step-1 agent was chlorthalidone: Hygroton®.

The primary agent used by the HDFP in an effective low dose

Hygroton® 25 mg. one a day
(chlorthalidone USP)

Because there's nothing mild about mild hypertension

BRIEF SUMMARY

Indications: Hypertension, adjunctive therapy in edema. **Contraindications:** Anuria, hypersensitivity to chlorthalidone or other sulfonamide-derived drugs. **Warnings:** Should be used with caution in severe renal disease, impaired hepatic function or progressive liver disease. May add to or potentiate the action of other antihypertensive drugs. Sensitivity reactions may occur in patients with a history of allergy or bronchial asthma. There is a possibility of exacerbation or activation of systemic lupus erythematosus with thiazides, which are related to chlorthalidone. This has not been reported with chlorthalidone. Thiazides cross the placental barrier and appear in cord blood. Use in pregnant women requires that the anticipated benefits of the drug be weighed against possible hazards to the fetus. These hazards include fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. In nursing mothers, thiazides cross the placental barrier and appear in breast milk. If use of the drug is essential, the patient should stop nursing. **Precautions:** Periodic determination of serum electrolytes to detect possible electrolyte imbalance should be performed at appropriate intervals. All patients receiving chlorthalidone should be observed for clinical signs of fluid or electrolyte imbalance; namely, hyponatremia, hypochloremic alkalosis, and hypokalemia. Serum and urine electrolyte determinations are particularly important when the patient is vomiting excessively or receiving parenteral fluids. Medication such as digitalis may also influence serum electrolytes. Hypokalemia may develop with chlorthalidone as with any other potent diuretic, especially with brisk diuresis, when severe cirrhosis is present, or during concomitant use of corticosteroids or ACTH. Interference with adequate oral electrolyte intake will also contribute to hypokalemia. Digitalis therapy may exaggerate metabolic effects of hypokalemia especially with reference to myocardial activity. Any chloride deficit is generally mild and usually does not require specific treatment except under extraordinary circumstances (as in liver disease or renal disease). Dilutional hyponatremia may occur in edematous patients in hot weather. Hyperuricemia may occur or gout be precipitated in certain patients. Insulin requirements in diabetic patients may be increased, decreased, or unchanged and latent diabetes mellitus may become manifest. Chlorthalidone and related drugs may increase the responsiveness to tubocurarine. The antihypertensive effects of the drug may be enhanced in the postsympathectomy patient. Chlorthalidone and related drugs may decrease arterial responsiveness to norepinephrine. If progressive renal impairment becomes evident, as indicated by a rising nonprotein nitrogen or blood urea nitrogen, a careful reappraisal of therapy is necessary with consideration given to withholding or discontinuing diuretic therapy. Chlorthalidone and related drugs may decrease serum PBI levels without signs of thyroid disturbance. **Adverse Reactions:** Anorexia, gastric irritation, nausea, vomiting, cramping, diarrhea, constipation, jaundice (intrahepatic cholestatic jaundice), pancreatitis; dizziness, vertigo, paresthesias, headache, xanthopsia; leukopenia, agranulocytosis, thrombocytopenia, aplastic anemia; purpura, photosensitivity, rash, urticaria, necrotizing angiitis (vasculitis) (cutaneous vasculitis), Lyell's syndrome (toxic epidermal necrolysis). Orthostatic hypotension may occur and may be aggravated by alcohol, barbiturates or narcotics. Other adverse reactions include hyperglycemia, glycosuria, hyperuricemia, muscle spasm, weakness, restlessness, impotence. Whenever adverse reactions are moderate or severe, chlorthalidone dosage should be reduced or therapy withdrawn. **Usual Dose:** One tablet daily. **How Supplied:** Tablets—100 mg. (white, scored), 50 mg. (aqua) in bottles of 100, 1000 and 5000; 25 mg. (peach) in bottles of 100 and 1000; unit-dose blister packs, boxes of 100 (10 x 10 strips).

CLINICAL STUDIES

525 The Natural History of Idiopathic Dilated Cardiomyopathy

VALENTIN FUSTER, BERNARD J. GERSH, EMILIO R. GIULIANI, ABDUL J. TAJIK, ROBERT O. BRANDENBURG and ROBERT L. FRYE

This long-term retrospective follow-up study of 104 patients with idiopathic dilated cardiomyopathy reveals that age, cardiothoracic ratio on chest X-ray film and cardiac index are highly predictive of the clinical course. The combination of cardiac index and cardiothoracic ratio permitted 86 percent of the patients to be correctly classified with respect to 3 year survival. Twenty-four patients (23 percent) in this series survived. The occurrence of systemic emboli in 18 percent of patients who did not receive anticoagulant therapy and in none who received such therapy suggests that anticoagulant drugs should be used in this condition unless they are contraindicated. In the genesis of this condition possible etiologic risk factors of infectious-immunologic type may be important.

532 Prognosis in Hypertrophic Cardiomyopathy: Role of Age and Clinical, Electrocardiographic and Hemodynamic Features

WILLIAM McKENNA, JOHN DEANFIELD, AZHAR FARUQUI, DIANE ENGLAND, CELIA OAKLEY and JOHN GOODWIN

The history at the time of diagnosis and changes in symptoms during follow-up proved better predictors of poor prognosis than electrocardiographic or hemodynamic measurements in this retrospective study of the clinical course of 254 patients with hypertrophic cardiomyopathy. The combination of young age, syncope at diagnosis, severe dyspnea at last follow-up and a family history of hypertrophic cardiomyopathy and sudden death best predicted sudden death. Mainly because of the high overall operative mortality rate (27 percent) the total 6 year mortality rate for surgically treated patients exceeded that of the medically treated ones. In this series 55 percent of the deaths were sudden and associated with a previous history of syncope. Ventricular arrhythmia is probably the antecedent event in most sudden deaths. Traditional treatment with beta receptor blocking drugs and the newer treatment with verapamil are effective against ventricular arrhythmias in hypertrophic cardiomyopathy.

539 Comparison of Coronary Arteriographic Findings During Angina Pectoris Associated With S-T Elevation or Depression

HIROFUMI YASUE, SHINGO OMOTE, AKINORI TAKIZAWA, NAGAO MASAO, HIROMITSU HYON, SHINICHIRO NISHIDA and MINORU HORIE

Coronary arteriographic studies during 64 attacks of induced or spontaneous angina pectoris indicate that angina pectoris associated with S-T segment elevation usually indicates more severe myocardial ischemia than angina associated with S-T segment depression. The former represents transmural ischemia and the latter subendocardial ischemia. The majority (76.3 percent) of the attacks with S-T elevation were associated with total occlusion of a major coronary artery. Spasm of an artery supplying an area of myocardium represented by S-T segment shift in the electrocardiogram appeared during an attack of angina, and disappeared with subsidence of the attack after nitroglycerin administration in all 38 attacks associated with S-T segment elevation and in 22 of the 26 attacks associated with S-T depression. The majority (76.9 percent) of angina attacks associated with S-T segment depression were accompanied by either subtotal spastic occlusion or diffuse narrowing of a major coronary artery.

Medtronic Spectraflex™ leads.

Because sometimes life depends on a firm foothold.

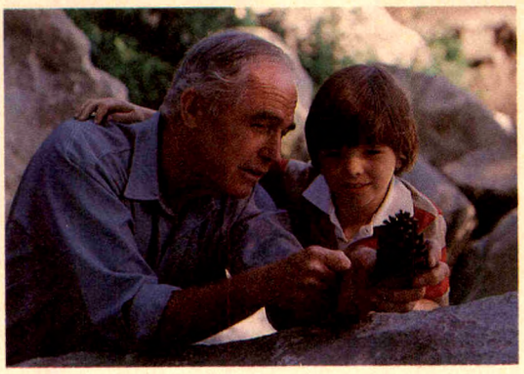
A tiny sprout takes a stubborn grip on a rock, digs in and grows into a mighty tree. In the same way, your pacemaker patient's long-term vigor can depend on the firm anchoring of a tiny lead.

That's why Medtronic offers you the world's broadest spectrum of positive anchoring leads, including the Spectraflex unipolar and bipolar tined models, the new standards of ventricular pacing technology. Medtronic introduced the first positive anchoring leads. And now, with Spectraflex leads, we can help you make both ventricular and atrial-ventricular pacing simpler and more effective.

For AV pacing in most patients, one thin, slippery Spectraflex lead is easily passed in the same vein with one of our new urethane atrial leads.

In both AV and ventricular pacing, you can expect superior performance from Spectraflex leads. They are designed for better electrical efficiency, less likelihood of fracture and, of course, stability because of the proven effectiveness of their tines. The urethane-wrapped DBS (drawn brazed strand) coil conductors offer five times the flex life of older style leads. And the ring-tip electrode provides efficient sensing and stimulation thresholds while minimizing tissue trauma.

Only Medtronic's proven, reliable technology could make these bold steps possible. And we'll keep setting the standards for leads, pacemakers and pacing support, to help you give your patients a firmer hold on life.



Medtronic

Leading the way to man's heart.

A13

MEDTRONIC PRODUCT INFORMATION SUMMARY

Medtronic Implantable Pacing Leads and Accessories

Intended Use–

Medtronic implantable pacing leads and accessories are designed to be used with Medtronic pulse generators as part of a cardiac pacing system (see product labeling for specific directions regarding applications).

Contraindications–

Endocardial pacing leads are contraindicated in the presence of tricuspid valvular disease.

Myocardial leads are contraindicated for a patient whose myocardium is thin-walled, suffused with fat or infarcted in the area of electrode placement.

Myocardial leads may be contraindicated in the older high-risk patients with a low tolerance to general anesthesia.

Use of the introducer is contraindicated if the patient has a known or suspected obstruction in the subclavian vein. There is increased risk of pneumothorax. Poor healing may result in the patient who has had irradiation to the anterior chest.

Temporary leads are contraindicated for a patient whose myocardium is thin-walled, suffused with fat, or infarcted in the area of electrode placement.

Warnings–

An implanted lead or lead/adaptor combination constitutes a direct, low-resistance current path to the myocardium. During the connection and testing procedures, only battery-powered pulse generators should be used with the lead system to protect against ventricular fibrillation induced by alternating current leakage. Extreme caution must be taken to properly ground all line-powered equipment used in the vicinity of the patient.

Lead adaptors, lead extenders and repair kits should not be used if the integrity of the lead is in doubt.

Precautions–

The pacing system may cease to function due to lead-related problems such as displacement, fracture, fibrotic tissue formation and elevated thresholds.

Side Effects–

Body rejection phenomena, infection, erosion or migration through body tissue, transvenous lead-related thrombosis, embolism.

How Supplied–

Medtronic permanent implantable leads and accessories are supplied sterilized and, in most cases, individually packaged.

In chronic CHF . . . physiologically consistent with the disease state and its therapy

Aldactone®
(spironolactone 25 mg)

WARNING

Spironolactone has been shown to be a tumorigen in chronic toxicity studies in rats (see Warnings). Aldactone should be used only in those conditions described under Indications. Unnecessary use of this drug should be avoided.

INDICATIONS: *Diagnosis and treatment of primary hyperaldosteronism. Essential hypertension, edema of congestive heart failure and the nephrotic syndrome, when other measures are considered inappropriate. Cirrhosis of the liver accompanied by edema and/or ascites. Hypokalemia.* ***CONTRAINDICATIONS:*** *Anuria, acute renal insufficiency, significant impairment of renal function, or hyperkalemia.* ***WARNINGS:*** *Excessive potassium intake may cause hyperkalemia. Potassium supplements should not be given with Aldactone. Do not administer concurrently with other potassium-sparing diuretics. Spironolactone has been shown to be a tumorigen in chronic toxicity studies in rats. In one study using 25, 75, and 250 times the usual daily human dose (2 mg./kg.) there was a statistically significant dose-related increase in benign adenomas of the thyroid and testes. In female rats there was a statistically significant increase in malignant mammary tumors at the mid-dose only. In male rats there was a dose-related increase in proliferative changes in the liver. At the highest dosage level (500 mg./kg.) the range of effects included hepatocytomegaly, hyperplastic nodules and hepatocellular carcinoma; the last was not statistically significant.* ***PRECAUTIONS:*** *Patients should be carefully evaluated for possible disturbances of fluid and electrolyte balance. Hyperkalemia may occur in patients with impaired renal function or excessive potassium intake and can cause cardiac irregularities which may be fatal. Reversible hyperchloremic metabolic acidosis may occur in some patients with decompensated hepatic cirrhosis. Hyponatremia may be caused or aggravated, especially when Aldactone is administered in combination with other diuretics. Transient elevation of BUN and/or mild acidosis may occur. Aldactone potentiates the effect of other diuretics or antihypertensive agents, particularly ganglionic blocking agents; therefore the dosage of such drugs should be reduced by at least 50 percent when adding Aldactone. Gynecomastia may develop and in rare instances some breast enlargement may persist. Vascular responsiveness to norepinephrine may be reduced. Spironolactone may cross the placental barrier. Use in pregnant women requires that the anticipated benefit be weighed against possible hazard to the fetus. Breast feeding should be discontinued when Aldactone is being used.* ***ADVERSE REACTIONS:*** *Gynecomastia is observed not infrequently. Gastrointestinal symptoms including cramping and diarrhea, drowsiness, lethargy, headache, maculopapular or erythematous cutaneous eruptions, urticaria, mental confusion, drug fever, ataxia, inability to achieve or maintain erection, irregular menses or amenorrhea, postmenopausal bleeding, hirsutism and deepening of the voice. Carcinoma of the breast has been reported but a cause-and-effect relationship has not been established. Adverse reactions are usually reversible upon discontinuation of the drug.* ***DOSAGE AND ADMINISTRATION: For primary hyperaldosteronism:*** *400 mg. daily for three to four weeks (long test), or for four days (short test). For preparation for surgery or for long-term maintenance therapy, 100 to 400 mg. daily.* ***For edema in adults:*** *Initial daily dosage is 100 mg. in divided doses but may range from 25 to 200 mg. daily. If after five days an adequate diuretic response has not occurred, a second diuretic which acts more proximally in the renal tubule may be added. The dosage of Aldactone should remain unchanged when other diuretic therapy is added.* ***For edema in children:*** *Initial daily dosage should provide approximately 1.5 mg. per pound of body weight (3.3 mg./kg.) in divided doses.* ***For essential hypertension:*** *Initial adult daily dosage of 50 to 100 mg. in divided doses, alone or with diuretics which act more proximally in the renal tubule, or with other antihypertensive agents. Continue treatment for at least two weeks since maximal response may not occur before this time. Adjust subsequent dosage according to patient response.* ***For hypokalemia:*** *25 to 100 mg. daily in divided doses.*

111

In chronic CHF . . . when other measures are inadequate or considered inappropriate

Physiologically consistent with the disease state and its therapy

Aldactone®

(spironolactone 25 mg)

the "uncomplicator"

Effective and sustained diuresis

Aldactone, acting primarily at site IV in the distal convoluted tubule, competitively blocks the action of aldosterone. Aldactone thus promotes the excretion of sodium and water while it spares potassium.

Combats secondary volume buildup

The action of Aldactone is distinct from other potassium-sparing diuretics. Because it specifically antagonizes aldosterone, secondary volume buildup is mitigated, while edema and congestion are relieved.

Unique potassium-regulating effect

The unique potassium-regulating mechanism of Aldactone can prevent hypokalemia, with limited risk of hyperkalemia. Such side effects of conventional diuretics as hypokalemic alkalosis, digitalis toxicity, and cardiac arrhythmias are unlikely to occur. Consult Aldactone prescribing information for the side effects of spironolactone.

Limitations to consider

Spironolactone has been shown to be a tumorigen in chronic toxicity studies in rats. Thus, Aldactone should be prescribed only when other measures are considered inadequate or inappropriate. (See boxed warning and Warnings *section of Aldactone prescribing information.)*

SEARLE

Before prescribing, please consult the complete prescribing information, a brief summary of which appears on the facing page.

547 Coronary Flow Studies in Patients With Left Ventricular Hypertrophy of the Hypertensive Type. Evidence for an Impaired Coronary Vascular Reserve

AUGUSTO D. PICHARD, RICHARD GORLIN, HARRY SMITH, JOHN AMBROSE and JOSE MELLER with the technical assistance of WILLIAM KING and ONDINA BOBADILLA

Analysis of the hyperemic reaction to the selective injection of contrast agent into the coronary arteries of 25 patients with aortic stenosis and left ventricular hypertrophy indicates that there is a reduction in coronary vascular reserve related to the ischemic component of their hypertrophic heart disease. The decreased coronary vascular reserve was proportional to the increase in left ventricular mass and the decreased left ventricular-aortic diastolic gradient and aortic diastolic pressure. The clinical deterioration of patients with left ventricular hypertrophy secondary to aortic stenosis may well be related to left ventricular failure secondary to acute or chronic ischemia.

555 Assessment of Left Ventricular Function by Radionuclide Angiography During Induced Supraventricular Tachycardia

STEVEN SWIRYN, DAN PAVEL, ERNEST BYROM, CHRISTOPHER WYNDHAM, RAYMOND PIETRAS, ROBERT BAUERNFEIND and KENNETH M. ROSEN

Electrocardiographically synchronized radionuclide angiography performed before, during and after induced paroxysmal supraventricular tachycardia in 13 patients showed that the tachycardia was characterized by a marked decrease in left ventricular end-diastolic and stroke volumes, increased ejection rate and cardiac output, and no significant change in ejection fraction. The mechanism of the tachycardia was atrioventricular (A-V) reentrance using an anomalous pathway for retrograde conduction in seven patients, A-V nodal reentrance in five and atrial reentrance in one. Heart disease or very rapid heart rate during tachycardia modified the hemodynamic response and had a deleterious effect on ejection fraction. The hemodynamic features of paroxysmal supraventricular tachycardia are similar to those of rapid atrial pacing and not those of exercise.

562 Paroxysmal Atrial Fibrillation in the Wolff-Parkinson-White Syndrome

ROBERT A. BAUERNFEIND, CHRISTOPHER R. WYNDHAM, STEVEN P. SWIRYN, EDWIN V. PALILEO, BORIS STRASBERG, WILFRED LAM, DOUGLAS WESTVEER and KENNETH M. ROSEN

In this series of 88 patients with preexcitation the 30 patients with documented spontaneous atrial fibrillation were more likely to have inducible atrioventricular (A-V) reentrant tachycardia than were the patients without such documented atrial fibrillation. Organic heart disease of several different varieties was found in 13 (42 percent) of the patients with preexcitation and documented spontaneous paroxysmal atrial fibrillation. It is unclear why some patients with inducible reentrant tachycardia have atrial fibrillation and others do not. In the patients with organic heart disease atrial fibrillation could be related to hemodynamic changes. These results suggest that the administration of drugs to these patients to prevent paroxysmal supraventricular tachycardia could also prevent recurrence of atrial fibrillation since reentrant tachycardia may degenerate into rapid atrial fibrillation. The results imply that surgical division of the anomalous pathway (the retrograde limb of A-V reentrant tachycardia) could also prevent recurrence of atrial fibrillation.

570 Echocardiographic Abnormalities in Chronic Alcoholics With and Without Overt Congestive Heart Failure

EMMETT C. MATTHEWS, Jr., JULIUS M. GARDIN, WALTER L. HENRY, ALBERT A. Del NEGRO, ROSS D. FLETCHER, JERRY A. SNOW and STEPHEN E. EPSTEIN

M mode electrocardiographic studies in 11 symptomatic alcoholic patients with dilated (congestive) cardiomyopathy demonstrated significantly decreased left ventricular percent fractional shortening, along with significant increases in left ventricular systolic and diastolic dimensions, left atrial dimension and estimated left ventricular mass. In 15 (68 percent) of 22 asymptomatic chronic alcoholic patients similar studies showed significant increases in at least one of the following variables: left ventricular mass, left ventricular dimension, septal and left ventricular wall thicknesses and left atrial dimension; the most frequent abnormality (not considering thickness to radius ratio) was an increased left ventricular mass. These echocardiographic abnormalities in the group with asymptomatic chronic alcoholism did not correlate with the presence or absence of auscultatory abnormalities on physical examination and appear to reflect an earlier stage in the spectrum of alcoholic myocardial disease before the development of dilated congestive cardiomyopathy.

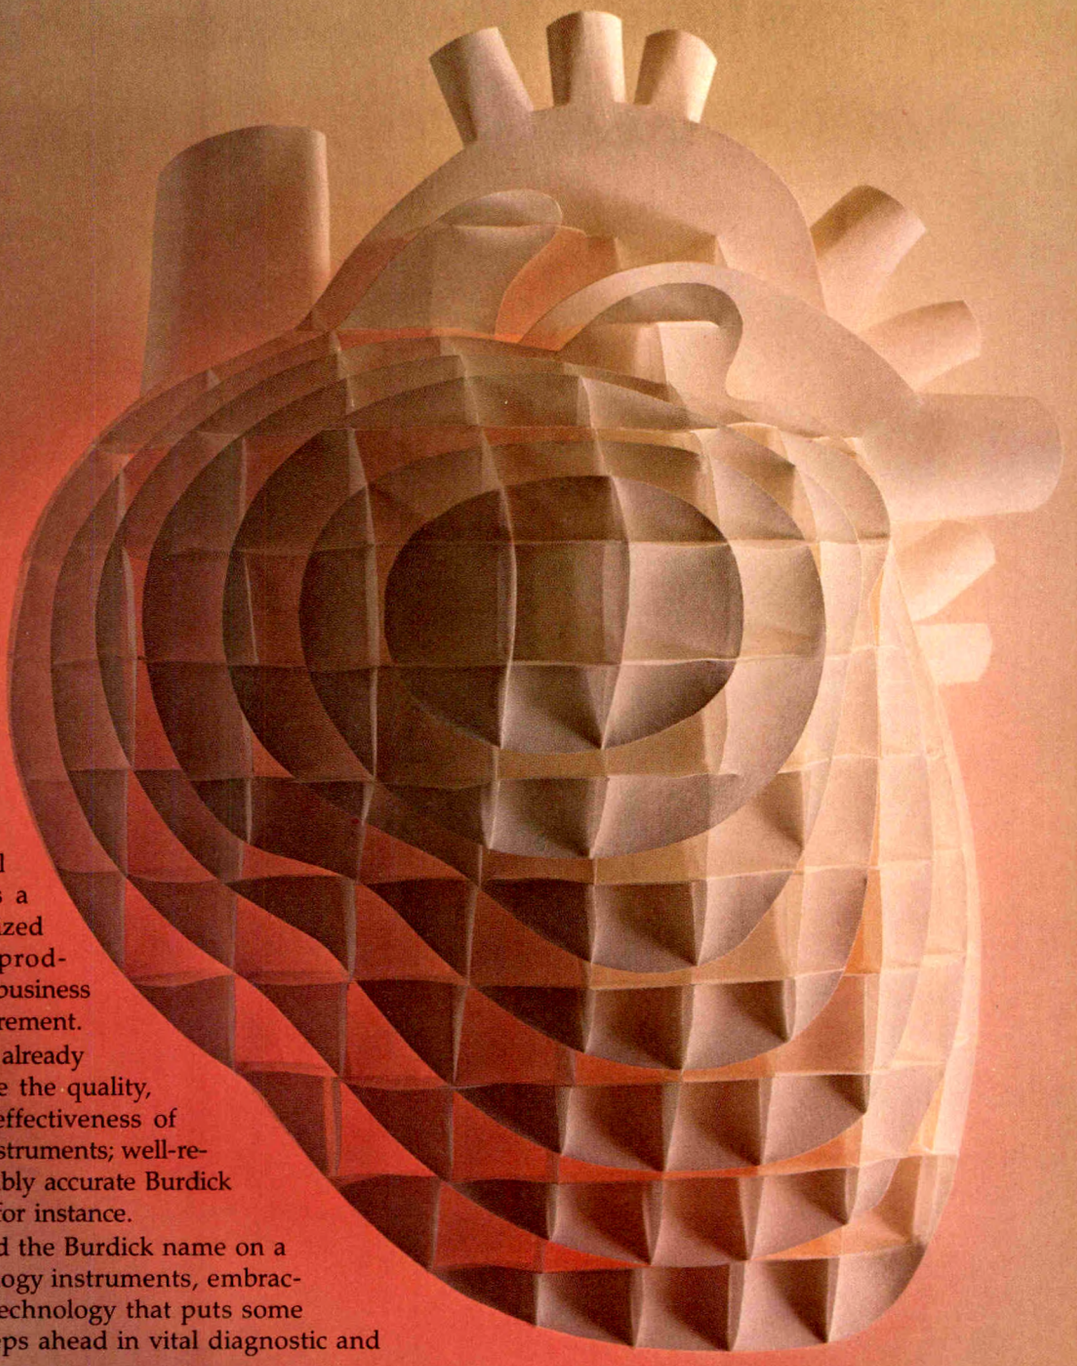
We give the heart our undivided attention. In many different ways.



Serving the life-extending needs of the medical profession requires a full range of specialized electronic medical products. At Burdick, our business is fulfilling that requirement.

Chances are you already know and appreciate the quality, reliability and cost effectiveness of Burdick cardiology instruments; well-respected and dependably accurate Burdick electrocardiographs, for instance.

Today, you'll find the Burdick name on a new group of cardiology instruments, embracing state-of-the art technology that puts some Burdick products steps ahead in vital diagnostic and monitoring service.

One example, EK-8, an *automatic* single channel ECG that produces the electrocardiogram in 38 seconds. Another: BETA™, the new Burdick ECG transmission and analysis system; a computerized ECG system that includes 3-dimensional Vector analysis. Vector, combined with Scaler data, produces the most complete interpretation, unmatched by any other computerized analysis system.

Burdick has consistently made important and timely innovations in cardiac products — electrocardiographs, monitors and defibrillators, cardiac emergency systems, ambulatory monitoring systems, exercise tolerance systems; and more.

For information, or a demonstration of any of these products, call or write

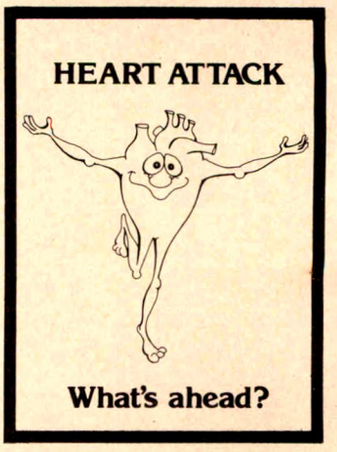
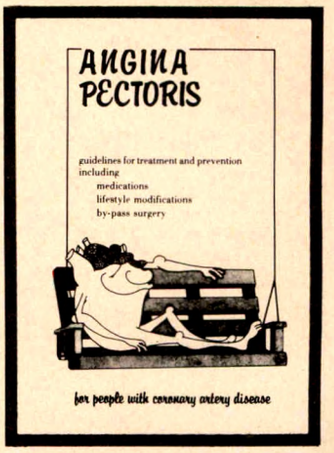
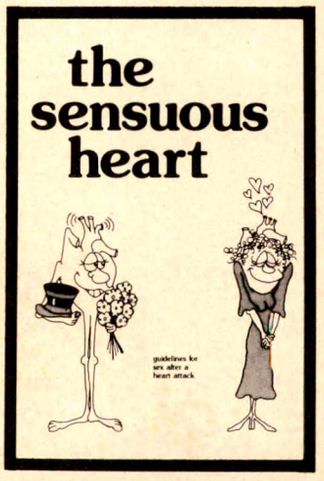
BEEF UP YOUR PATIENT EDUCATION

Order from Pritchett & Hull



Explanations of coronary artery disease, angina pectoris, acute myocardial infarction or congestive heart failure can be very confusing to the average patient. This is why Pritchett & Hull patient education books are so important. The clear illustrations and concise texts help you explain complicated medical conditions. This leaves your patients feeling good about themselves and good about you. You can even personalize the material by using the ample space throughout each book to write in your special instructions about diet, medications or exercise, for example. Pritchett & Hull patient education books are for adult patients, and the reading level is that of an average, popular magazine. At present, these materials are used by hospitals, clinics and private practice physicians throughout the U.S. and in many foreign countries. Current titles include:





MOVING RIGHT ALONG AFTER OPEN HEART SURGERY
(Reviews by-pass surgery, valvular surgery, ASD repair) Also available in Spanish.

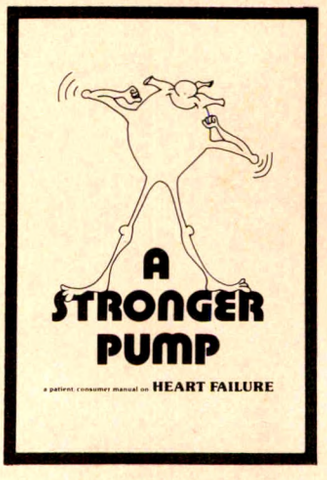
HEART ATTACK, WHAT'S AHEAD?
(Discusses AMI from hospitalization to recovery at home) Available in Spanish May 1, 1981.

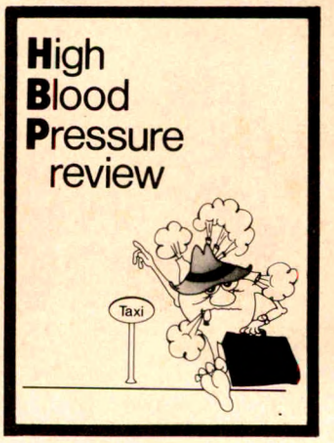
ANGINA PECTORIS
(Reviews risk factors for coronary artery disease, use of NTG; mentions potential for by-pass surgery)

THE SENSUOUS HEART
(Guidelines for sex after AMI)

A STRONGER PUMP
(Treatment for congestive heart failure explained in terms of rest, diet and medications)

HIGH BLOOD PRESSURE REVIEW
(For patients with essential hypertension. Includes information on diet, smoking, exercise and relaxation)





Beef up your patient teaching. **WRITE PRITCHETT & HULL ASSOCIATES, INC., 2122 Faulkner Rd. N.E., Atlanta, Georgia 30324** for our free newspaper catalog or order a Sample Pack B of the above 6 books and include a check or money order for $18.00 (+ sales tax if a Georgia resident).

8½ x 11 paperbacks

We've helped thousands of physicians know their patients by heart.
And that's a tangible expression of leadership in a highly specialized area of health care. Burdick electrocardiographs and other cardiac care equipment are used by thousands of physicians throughout the world.
More importantly, the Burdick name is respected for its assurance of electronic medical instruments with superior technology, long and dependable service and uncompromised quality.
For instance, Burdick was among the early developers of heated stylus direct-recording electrocardiographs. Today, our ECG instruments–single and multi-channel–are a model for accuracy and clarity.
Cardiac monitors, cardiac emergency systems, exercise tolerance testing systems and ambulatory monitors broaden our line of cardiac care products and fulfill our commitment to the development of quality cardiology instrumentation.
Every product we make is related to the heart and cardiology. That commitment is firm and continuous. Physicians in offices, clinics and hospitals get to know their patients better because of it.

Bayer® Aspirin

For reducing the risk of transient ischemic attacks or stroke in men who have had transient ischemia of the brain due to fibrin platelet emboli

THE DAWN OF A NEW ERA IN PREVENTIVE MEDICINE

Recently, an official government bulletin indicated that the following professional guideline labeling will be published:

There is evidence that aspirin is safe and effective for reducing the risk of recurrent transient ischemic attacks or stroke in men who have had transient ischemia of the brain due to fibrin platelet emboli.

There is no evidence that aspirin is effective in reducing TIA's in women, or is of benefit in the treatment of completed strokes in men or women.

Patients presenting with signs and symptoms of TIA's should have a complete medical and neurologic evaluation.

Consideration should be given to other disorders which resemble TIA's.

It is important to evaluate and treat, if appropriate, other diseases associated with TIA's and stroke, such as hypertension and diabetes.

The recommended dosage for this new indication is 1,300 mg/day (650 mg twice/day or 325 mg four times a day).

Prostaglandin inhibition—the key to aspirin's success

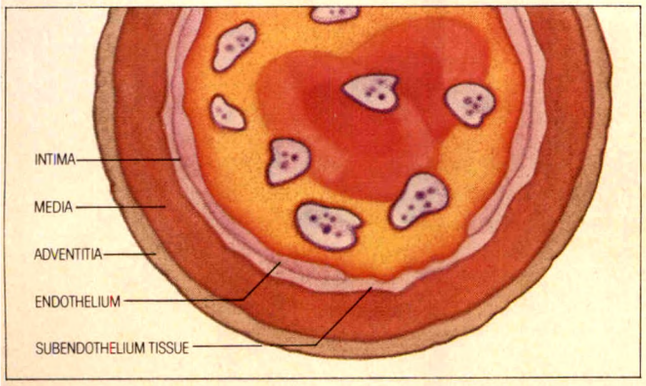
With the ability of aspirin to reduce the risk of recurrent TIA's and stroke clearly demonstrated in two major multicenter studies,[1,2] physicians throughout the country can now provide their own TIA patients with the prophylactic benefits of Bayer Aspirin.

At the same time, important new research is being conducted to determine the full scope of aspirin benefits in vascular disease...and in many other disorders involving prostaglandin synthesis.

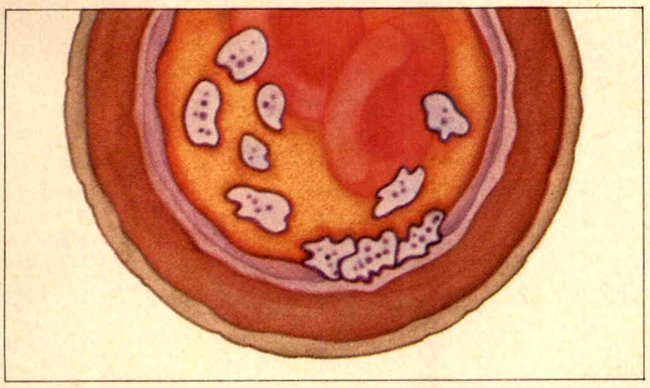
It has become apparent that many of aspirin's therapeutic effects—including its analgesic, antipyretic, anti-inflammatory and antithrombotic actions, can be traced entirely, or in part, to its ability to inhibit prostaglandin formation.

Prostaglandins are produced by every organ in the body with far reaching effects.[3] In vascular disease, for example, it is the excess production of the prostaglandin derivative, thromboxane A_2, that can ultimately lead to embolus formation.

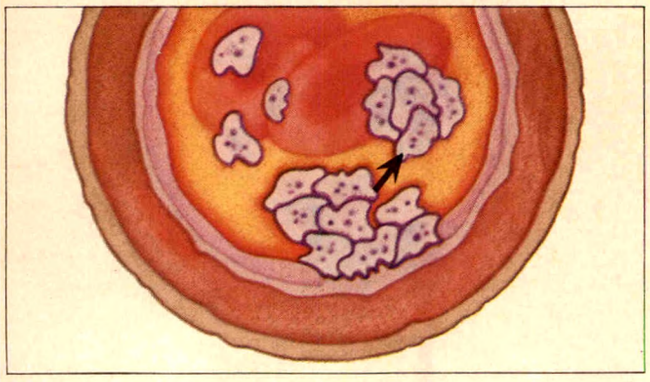
Cross-section of artery—artist's interpretation of circulating platelets encountering area of erosion in arterial wall.



Cerebrovascular clot formation begins when platelets circulating in the blood encounter an area of vascular erosion (usually predisposed by atherosclerosis)...with its exposed subendothelial tissue and collagen.



Through a series of prostaglandin interactions, a platelet collagen reaction takes place—first provoking platelet adhesion, then stimulating a self-perpetuating process of secretion, and finally, aggregation. Once formed, thrombi may dislodge.



By inhibiting platelet cyclo-oxygenase, an enzyme that mediates prostaglandin formation, aspirin inhibits thromboxane synthesis, prevents adhesion and thrombus formation and precludes thrombus dislodgment and subsequent TIA or stroke.

Bayer Aspirin and continuing investigations

Of the large number of pharmaceutical agents capable of altering platelet function, only aspirin has been shown to produce effects that are irreversible for the life of the platelet.[4]

Thus, the use of aspirin is being intensively investigated in a number of possible new clinical areas in which its antiplatelet, prostaglandin-inhibiting effects may be beneficial.

Not surprisingly, Bayer Aspirin has been the aspirin chosen for a large number of past and present studies. Bayer Aspirin actually exceeds U.S.P. requirements in critical areas such as aspirin content per tablet, dissolution time and free salicylic acid content. Over 100 quality-control tests help assure that the therapeutic dose recommended is the dose patients receive.

The Bayer Company is pleased not only to lend its continuing support to wide-ranging investigational studies, but to provide the medical community with comprehensive services and materials concerning aspirin.

The ability to reduce the risk of TIA or stroke with a drug as widely accepted, well tolerated and inexpensive as Bayer Aspirin, certainly represents the dawn of a new era in preventive medicine.

EXPERIMENTAL STUDIES

579 Adrenergic Regulation of Total Systemic Distensibility. Venous Distensibility Effects of Norepinephrine and Isoproterenol Before and After Selective Adrenergic Blockade

DAVID L. RUTLEN, EDWARD W. SUPPLE and WILLIAM JOHN POWELL, Jr.

These experimental studies in 51 dogs before and after selective adrenergic receptor blockade with phenoxybenzamine and propranolol revealed that the norepinephrine effect was mediated almost entirely through alpha adrenergic receptor stimulation and the isoproterenol effect mostly through beta adrenergic stimulation. Alpha and beta adrenergic receptor stimulation with norepinephrine and isoproterenol is associated with sustained increases in total systemic vascular distensibility and would be expected to be associated with diminished increases in venous pressure, venous return and cardiac performance when a given amount of volume is added to the intravascular space. These data suggest that the increase of sympathetic tone in the patient with congestive heart failure may benefit the patient in that the venous pressure would be increased much less for a given increment in vascular volume and thereby protect the patient from central volume overload, pulmonary edema or ascites.

589 Production of a Critical Coronary Arterial Stenosis in Closed Chest Laboratory Animals. Description of a New Nonsurgical Method Based on Standard Cardiac Catheterization Techniques

HENRY GEWIRTZ and ALBERT S. MOST

This study demonstrates that a critical intraluminal coronary arterial stenosis can be created rapidly and maintained in a closed chest dog by inserting an occlusive plastic truncated cone with a narrow central internal lumen into the animal's left anterior descending coronary artery using standard cardiac catheterization technique. During atrial pacing the endocardial to epicardial flow ratio decreased considerably in myocardium distal to the stenosis but remained unchanged in the left circumflex arterial zone. The data further indicate that the subendocardial layer of the heart is most vulnerable to ischemia and that some vasodilator reserve persists in epicardial vessels distal to a critical coronary stenosis. This method avoids many problems associated with open heart surgery and general anesthesia and provides an improved model for the study of myocardial blood flow and left ventricular function.

597 Differential Effects of Renografin-76 on the Ischemic and Nonischemic Myocardium

HAJIME YAMAZAKI, VIDYA S. BANKA, MONTY M. BODENHEIMER, SHIGEHITO HATTORI, JAI B. AGARWAL and RICHARD H. HELFANT

This dog study demonstrates that the myocardial depressant effects of an intracoronary injection of Renografin-76 are more pronounced and 4 to 5 times more prolonged in the ischemic myocardium than in normally perfused myocardium. These effects are neither abolished by the prior administration of nitroglycerin nor solely due to the hyperosmolarity or sodium concentration of the solution. Coronary flow reserve appears to play an important role in determining the duration of the depressant effects produced by injection of contrast medium. These results may be particularly relevant to coronary injections of Renografin-76 in patients with left main coronary arterial stenosis in whom the risk of coronary arteriography is recognizably high.

METHODS

603 Accuracy of Systolic Time Intervals in Detecting Abnormal Left Ventricular Performance in Coronary Artery Disease

RICHARD S. STACK, YOUNG H. SOHN and ARNOLD M. WEISSLER

This prospective analysis of noninvasively determined systolic time intervals as a measure of global left ventricular performance in 66 consecutive patients with a previous myocardial infarction, 44 patients with angina pectoris and no evidence of a previous myocardial infarction and 41 control patients with atypical chest pain and normal coronary arteries and left ventricular performance showed a correlation of 0.84 for the ratio of preejection period and left ventricular ejection time (PEP/LVET). Among the patients with coronary artery disease with and without previous myocardial infarction, PEP/LVET proved equivalent to the ejection fraction in identifying the patients with normal and abnormal left ventricular performance. On the basis of the group data analysis, the investigators conclude that PEP/LVET affords an accurate expression of the global performance of the left ventricle in coronary artery disease.

97.5% HOLTER DETECTION ACCURACY

HOLTER II/AUTOSCAN

The Accuracy

Holter II/Autoscan is the ONLY Holter System that computer analyzes every ECG complex on a "real time", beat-by-beat basis, DURING the actual patient monitoring period. Every ECG complex is compared to that patient's averaged updated "normal" complex for changes in rate, rhythm, morphology and signal quality (artifact). Since this computer analysis is performed at "real-time" rather than 60, 120, 240, or 480 times normal, Holter II/Autoscan has achieved a level of detection accuracy and ease of operation not possible with any other Holter system. Clinical Studies* have demonstrated an average of 97.5% quantitative detection accuracy and 100% qualitative detection accuracy. And, since the tape you receive from the patient is completely "pre-analyzed", only 6 minutes of operator time is required to process the tape.

The Challenge

Holter manufacturers' advertising often contains claims of increased accuracy of their respective systems. However, data to support these claims are rarely, if ever, provided. Now IMC has taken the lead with the only validated Holter system on the market.

WE CHALLENGE YOU TO COMPARE HOLTER II/AUTOSCAN:

- **TO YOUR PRESENT HOLTER SYSTEM**
- **TO ANY HOLTER SYSTEM YOU ARE CONSIDERING FOR PURCHASE**

If you want to know what you've been (or will be) missing, check the system you want to compare on the adjoining page and send it along with your name and address to IMC or call our toll free phone number. We will send you a real patient Holter tape compatible with the system you indicate, a hand count of every abnormal complex classified by type of anomaly, and the detection accuracy of the Holter II/Autoscan System on that tape.

We know you'll find the results to be enlightening!

Liquid K...
For the birds

Slow-K... No squawks

Proved record of safety

There are 5 years of U.S. clinical experience behind Slow-K. The 8 mEq tablet has proved safe and effective in over 4 million patients in the U.S. alone.*,†

25¢ a day

The cost of a day's therapy averages less than a quarter.‡

Acceptability

Slow-K has an unparalleled record of patient compliance.

No taste problems

Patients prefer Slow-K to unpalatable liquid.

Salt of choice (KCl)

The preferred salt to correct the hypokalemic alkalosis that may result after long-term use of diuretics.

*Slow-release potassium chloride tablets should be reserved for patients who cannot tolerate or have compliance problems with liquid K preparations. The total number of GI lesions in both foreign countries and the United States remains less than one per 100,000 patient-years.

†Data on file, CIBA Pharmaceutical Company.

‡Average cost per day based on Pharmaceutical Data Services audit.

4 million patients,
5 years of U.S. clinical experience†

potassium chloride slow-release tablets 8 mEq

Please turn page for brief prescribing information.

CIBA

SLOW-K®
potassium chloride slow-release tablets

DESCRIPTION
Slow-K is a sugar-coated (not enteric-coated) tablet containing 600 mg potassium chloride (equivalent to 8 mEq) in a wax matrix. This formulation is intended to provide a controlled release of potassium from the matrix to minimize the likelihood of producing high localized concentrations of potassium within the gastrointestinal tract.

INDICATIONS
BECAUSE OF REPORTS OF INTESTINAL AND GASTRIC ULCERATION AND BLEEDING WITH SLOW-RELEASE POTASSIUM CHLORIDE PREPARATIONS, THESE DRUGS SHOULD BE RESERVED FOR THOSE PATIENTS WHO CANNOT TOLERATE OR REFUSE TO TAKE LIQUID OR EFFERVESCENT POTASSIUM PREPARATIONS OR FOR PATIENTS IN WHOM THERE IS A PROBLEM OF COMPLIANCE WITH THESE PREPARATIONS.

1. For therapeutic use in patients with hypokalemia with or without metabolic alkalosis; in digitalis intoxication and in patients with hypokalemic familial periodic paralysis.

2. For prevention of potassium depletion when the dietary intake of potassium is inadequate in the following conditions: Patients receiving digitalis and diuretics for congestive heart failure; hepatic cirrhosis with ascites; states of aldosterone excess with normal renal function; potassium-losing nephropathy, and certain diarrheal states.

3. The use of potassium salts in patients receiving diuretics for uncomplicated essential hypertension is often unnecessary when such patients have a normal dietary pattern. Serum potassium should be checked periodically, however, and, if hypokalemia occurs, dietary supplementation with potassium-containing foods may be adequate to control milder cases. In more severe cases supplementation with potassium salts may be indicated.

CONTRAINDICATIONS
In patients with hyperkalemia, since a further increase in serum potassium concentration in such patients can produce cardiac arrest. Hyperkalemia may complicate any of the following conditions: chronic renal failure, systemic acidosis such as diabetic acidosis, acute dehydration, extensive tissue breakdown as in severe burns, adrenal insufficiency, or the administration of a potassium-sparing diuretic (*eg*, spironolactone, triamterene).

Wax-matrix potassium chloride preparations have produced esophageal ulceration in certain cardiac patients with esophageal compression due to enlarged left atrium.

All solid dosage forms of potassium supplements are contraindicated in any patient in whom there is cause for arrest or delay in tablet passage through the G.I. tract. In these instances, potassium supplementation should be with a liquid preparation.

WARNINGS
Hyperkalemia: In patients with impaired mechanisms for excreting potassium, administration of potassium salts can produce hyperkalemia and cardiac arrest. This occurs most commonly in patients given potassium intravenously but may also occur when given orally. Potentially fatal hyperkalemia can develop rapidly and be asymptomatic. Use of potassium salts in patients with chronic renal disease, or any other condition which impairs potassium excretion, requires particularly careful monitoring of the serum potassium concentration and appropriate dosage adjustment.

Interaction with Potassium-Sparing Diuretics: Hypokalemia should not be treated by the concomitant administration of potassium salts and a potassium-sparing diuretic (*eg*, spironolactone or triamterene), since the simultaneous administration of these agents can produce severe hyperkalemia.

Gastrointestinal lesions: Potassium chloride tablets have produced stenotic and/or ulcerative lesions of the small bowel and deaths. These lesions are caused by a high localized concentration of potassium ion in the region of a rapidly dissolving tablet, which injures the bowel wall and thereby produces obstruction, hemorrhage, or perforation. Slow-K is a wax-matrix tablet formulated to provide a controlled rate of release of potassium chloride and thus to minimize the possibility of a high local concentration of potassium ion near the bowel wall. While the reported frequency of small-bowel lesions is much less with wax-matrix tablets (less than one per 100,000 patient-years) than with enteric-coated potassium chloride tablets (40-50 per 100,000 patient-years) cases associated with wax-matrix tablets have been reported both in foreign countries and in the United States. In addition, perhaps because the wax-matrix preparations are not enteric-coated and release potassium in the stomach, there have been reports of upper gastrointestinal bleeding associated with these products. The total number of gastrointestinal lesions remains less than one per 100,000 patient-years. Slow-K should be discontinued immediately and the possibility of bowel obstruction or perforation considered if severe vomiting, abdominal pain, distention, or gastrointestinal bleeding occurs.

Metabolic acidosis: Hypokalemia in patients with metabolic *acidosis* should be treated with an alkalinizing potassium salt such as potassium bicarbonate, potassium citrate, or potassium acetate.

PRECAUTIONS
Potassium depletion is ordinarily diagnosed by demonstrating hypokalemia in a patient with a clinical history suggesting some cause for potassium depletion. In interpreting the serum potassium level, the physician should bear in mind that acute alkalosis *per se* can produce hypokalemia in the absence of a deficit in total body potassium, while acute acidosis *per se* can increase the serum potassium concentration into the normal range even in the presence of a reduced total body potassium. Treatment of potassium depletion, particularly in presence of cardiac disease, renal disease, or acidosis, requires careful attention to acid-base balance and appropriate monitoring of serum electrolytes, electrocardiogram, and clinical status of patient.

ADVERSE REACTIONS
Most common to oral potassium salts: nausea, vomiting, abdominal discomfort, and diarrhea. These symptoms are due to irritation of the gastrointestinal tract and are best managed by diluting the preparation further, taking the dose with meals, or reducing the dose.

One of the most severe adverse effects is hyperkalemia (see Contraindications and Warnings). There also have been reports of upper and lower gastrointestinal conditions including obstruction, bleeding, ulceration and perforation (see Contraindications and Warnings); other factors known to be associated with such conditions were present in many of these patients. Skin rash has been reported rarely.

DOSAGE AND ADMINISTRATION
Usual dietary intake of potassium by the average adult is 40 to 80 mEq per day. Potassium depletion sufficient to cause hypokalemia usually requires loss of 200 or more mEq of potassium from the total body store.

Dosage must be adjusted to the individual needs of each patient but is typically in the range of 20 mEq per day for prevention of hypokalemia to 40-100 mEq per day or more for treatment of potassium depletion.

Note: Slow-K slow-release tablets must be swallowed whole and never crushed or chewed.

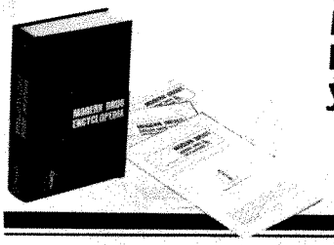
How thorough and unbiased is your drug reference?



If it's not MODERN DRUG ENCYCLOPEDIA, you can't be sure.

MODERN DRUG ENCYCLOPEDIA and Therapeutic Index 15th Edition
Arthur J. Lewis, MD, Executive Editor
Gertrude Dittus Gonzales, R.Ph., B.S. Pharm., Executive Editor
Charles L. Winek, Ph.D., Contributing Editor

The all new 15th Edition of MODERN DRUG ENCYCLOPEDIA is written especially for the practitioner who needs complete, objective information on prescription drugs.

An independent team of pharmacists and physicians has researched and edited all the facts on 3,000 prescription drugs. It passes this research on to you in an easy to absorb style that's perfectly suited to the tight schedule of a time pressed practitioner.

Some handbooks just reprint manufacturers' package inserts. They don't edit. Just print material manufacturer pays to have included.

Here's what careful planning does for MODERN DRUG ENCYCLOPEDIA:
- limits entries to prescription drugs. You don't waste time flipping through pages of extraneous drugs.
- lists over 3,000 pharmaceuticals, biologicals, and allergens in one a-z sequence.
- arranges entries by generic name. All brand names in one place.
- written in concise language for quick comprehension
- designed with a "strong focus" layout, easy-to-read type, and bold subject headings.

The 1,000 page main section arranges over 3,000 drugs alphabetically by generic name. Each entry covers vital facts about brand names and each manufacturer that markets their own brand.

Three a-z indexes provide instant access to all the material found in the main secton as follows:
- GENERAL INDEX of all brand generic names in handy alphabetic sequence.
- THERAPEUTIC INDEX of which drugs are prescribed for which purpose. Allows you a wide selection of therapy based on your patient's special needs.
- MANUFACTURERS INDEX of names and addresses and product names. Helps you identify the drug when you only know the manufacturer's name.

And, our Free Updating Service informs you of changes in specifications and introduces new drugs. These periodic supplements adopt the same easy-to-read format of the basic volume. You receive them free of charge until the publication of the next (16th) Edition.

Try using MODERN DRUG ENCYCLOPEDIA for 30 days at our risk. Then keep it only if you're convinced that it answers a practitioner's need for concise, easy to read information on prescription drugs.

Yorke Medical Books AJC 3/81
666 FIFTH AVENUE, NEW YORK, N.Y. 10103

Rest Exercise

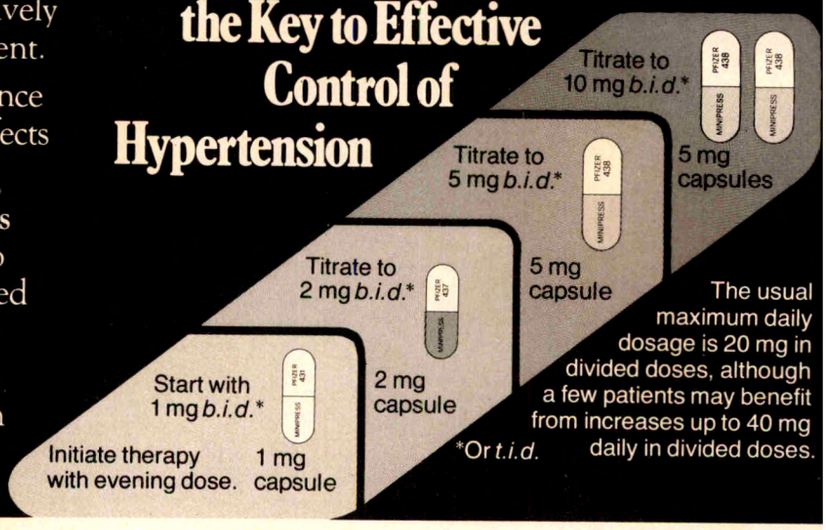
MINIPRESS®

(prazosin HCl) Capsules 1 mg, 2 mg, 5 mg

MINIPRESS®
(prazosin HCl) Capsules 1 mg, 2 mg, 5 mg

- **Effectively lowers elevated blood pressure by reducing peripheral resistance.**
- **Maintains cardiac output** which allows patients to maintain an active life style.
- **Maintains renal blood flow and glomerular filtration rate** so it can be used effectively even in patients with renal impairment.
- **Not a CNS agent** so patients experience few of the troublesome CNS side effects that impair their quality of life.
- **Cardiovascular response to exercise is preserved** so patients are less likely to experience the fatigue often associated with beta-blocker therapy.
- **A small percentage of patients** have experienced orthostatic hypotension and syncope.

B.I.D. Dosage Titration... the Key to Effective Control of Hypertension



The usual maximum daily dosage is 20 mg in divided doses, although a few patients may benefit from increases up to 40 mg daily in divided doses.

BRIEF SUMMARY
MINIPRESS® (prazosin hydrochloride) CAPSULES *For Oral Use*

INDICATIONS: MINIPRESS® (prazosin hydrochloride) is indicated in the treatment of hypertension. As an antihypertensive drug, it is mild to moderate in activity. It can be used as the initial agent or it may be employed in a general treatment program in conjunction with a diuretic and/or other antihypertensive drugs as needed for proper patient response.

WARNINGS: MINIPRESS (prazosin hydrochloride) may cause syncope with sudden loss of consciousness. In most cases this is believed to be due to an excessive postural hypotensive effect, although occasionally the syncopal episode has been preceded by a bout of severe tachycardia with heart rates of 120-160 beats per minute. Syncopal episodes have usually occurred within 30 to 90 minutes of the initial dose of the drug; occasionally they have been reported in association with rapid dosage increases or the introduction of another antihypertensive drug into the regimen of a patient taking high doses of MINIPRESS (prazosin hydrochloride). The incidence of syncopal episodes is approximately 1% in patients given an initial dose of 2 mg or greater. Clinical trials conducted during the investigational phase of this drug suggest that syncopal episodes can be minimized by limiting the initial dose of the drug to 1 mg, by subsequently increasing the dosage slowly, and by introducing any additional antihypertensive drugs into the patient's regimen with caution (see DOSAGE AND ADMINISTRATION). Hypotension may develop in patients given MINIPRESS who are also receiving a beta-blocker such as propranolol.

If syncope occurs, the patient should be placed in the recumbent position and treated supportively as necessary. This adverse effect is self-limiting and in most cases does not recur after the initial period of therapy or during subsequent dose titration.

Patients should always be started on the 1 mg capsules of MINIPRESS (prazosin hydrochloride). The 2 and 5 mg capsules are not indicated for initial therapy.

More common than loss of consciousness are the symptoms often associated with lowering of the blood pressure, namely, dizziness and lightheadedness. The patient should be cautioned about these possible adverse effects and advised what measures to take should they develop. The patient should also be cautioned to avoid situations where injury could result should syncope occur during the initiation of MINIPRESS (prazosin hydrochloride) therapy.

Usage in Pregnancy: Although no teratogenic effects were seen in animal testing, the safety of MINIPRESS (prazosin hydrochloride) in pregnancy has not been established. MINIPRESS (prazosin hydrochloride) is not recommended in pregnant women unless the potential benefit outweighs potential risk to mother and fetus.

Usage in Children: No clinical experience is available with the use of MINIPRESS (prazosin hydrochloride) in children.

ADVERSE REACTIONS: The most common reactions associated with MINIPRESS (prazosin hydrochloride) therapy are: dizziness 10.3%, headache 7.8%, drowsiness 7.6%, lack of energy 6.9%, weakness 6.5%, palpitations 5.3%, and nausea 4.9%. In most instances side effects have disappeared with continued therapy or have been tolerated with no decrease in dose of drug.

The following reactions have been associated with MINIPRESS (prazosin hydrochloride), some of them rarely. (In some instances exact causal relationships have not been established).

Gastrointestinal: vomiting, diarrhea, constipation, abdominal discomfort and/or pain.

Cardiovascular: edema, dyspnea, syncope, tachycardia.

Central Nervous System: nervousness, vertigo, depression, paresthesia.

Dermatologic: rash, pruritus.

Genitourinary: urinary frequency, incontinence, impotence.

EENT: blurred vision, reddened sclera, epistaxis, tinnitus, dry mouth, nasal congestion.

Other: diaphoresis.

Single reports of pigmentary mottling and serous retinopathy, and a few reports of cataract development or disappearance have been reported. In these instances, the exact causal relationship has not been established because the baseline observations were frequently inadequate.

In more specific slit-lamp and funduscopic studies, which included adequate baseline examinations, no drug-related abnormal ophthalmological findings have been reported.

DOSAGE AND ADMINISTRATION: The dose of MINIPRESS (prazosin hydrochloride) should be adjusted according to the patient's individual blood pressure response. The following is a guide to its administration:

Initial Dose: 1 mg two or three times a day. (See Warnings).

Maintenance Dose: Dosage may be slowly increased to a total daily dose of 20 mg given in divided doses. The therapeutic dosages most commonly employed have ranged from 6 mg to 15 mg daily given in divided doses. Doses higher than 20 mg usually do not increase efficacy, however a few patients may benefit from further increases up to a daily dose of 40 mg given in divided doses. After initial titration some patients can be maintained adequately on a twice daily dosage regimen.

Use With Other Drugs: When adding a diuretic or other antihypertensive agent, the dose of MINIPRESS (prazosin hydrochloride) should be reduced to 1 mg or 2 mg three times a day and retitration then carried out.

HOW SUPPLIED: MINIPRESS (prazosin hydrochloride) is available in 1 mg (white #431), 2 mg (pink and white #437) capsules in bottles of 250, 1000, and unit dose institutional packages of 100 (10 x 10's); and 5 mg (blue and white #438) capsules in bottles of 250, 500 and unit dose institutional packages of 100 (10 x 10's).

More detailed information available on request.

Pfizer **LABORATORIES DIVISION**
PFIZER INC.

contrast, in the 15 patients who received medical treatment, operation was delayed until a mean age of 7.5 years, and 13 of the 15 survived until a mean age of 14.5 years. Delay of operative intervention until at least age 18 months is therefore recommended because coronary arterial surgery in the 1st year of life in infants with severely depressed myocardial function has an extremely high mortality rate of 75 percent and because many sick infants can be treated medically and survive.

649 **Coronary Artery Disease in the Hurler Syndrome**

FRANK C. BROSIUS, III and WILLIAM C. ROBERTS

Necropsy data in six patients aged 3 to 16 years with the Hurler syndrome revealed narrowing of the major epicardial coronary arteries, produced mainly by a combination of Hurler cells, granular cells, collagen and acid mucopolysaccharide material. The coronary disease is usually diffuse and severe. In fact, the Hurler syndrome is responsible for the most severe coronary narrowing in childhood. The lumen in every 5 mm segment of coronary artery was centrally located, or nearly so, and all portions of the arterial lining were covered by the Hurler type plaque. Despite these severe lesions, no patient had clinical symptoms of cardiac dysfunction or evidence of myocardial ischemia during life.

654 **Two Dimensional Echocardiographic Evaluation of Mustard Operation for d-Transposition of the Great Arteries**

KALIM U. AZIZ, MILTON H. PAUL, SAROJA BHARATI, ROGER B. COLE, ALEXANDER J. MUSTER, MAURICE LEV and FAROUK S. IDRISS

This study demonstrates the value of two dimensional sector scan echocardiography in assessing qualitatively and quantitatively the morphologic structural abnormalities of the surgically revised systemic and pulmonary venous atria in 17 patients with d-transposition of the great arteries after the Mustard operation. The site and severity of these abnormalities in 10 of the patients correlated accurately with the angiographic appearances. Tricuspid regurgitation in six patients was shown to lead to a grossly enlarged pulmonary venous atrium with dilatation in all of its segments. The echocardiographic diagnosis of tricuspid regurgitation is indirect because regurgitation of the blood into the pulmonary venous atrium cannot be observed directly. The cause of the tricuspid insufficiency in complete d-transposition is probably related to pre-, intra- and postoperative factors. This noninvasive method can facilitate longitudinal follow-up and permit assessment of progression of the lesions during growth.

REPORTS ON THERAPY

665 **Comparison of Hemodynamic Actions of Pirbuterol and Dobutamine on Cardiac Function in Severe Congestive Heart Failure**

NAJAM A. AWAN, KATHLEEN E. NEEDHAM, MARK K. EVENSON and DEAN T. MASON

Comparison of the hemodynamic effects of pirbuterol, a new oral beta adrenergic receptor agonist, with those of intravenous dobutamine in nine patients with severe heart failure demonstrates oral pirbuterol exerts dobutamine-like beneficial hemodynamic effects on left ventricular pump function but causes a greater decrease in total systemic vascular resistance consistent with its combined inotropic and peripheral vasodilator actions. Neither drug caused left ventricular ischemia or increased ventricular arrhythmia. The beneficial effects of pirbuterol are probably caused by its combined central inotropic and peripheral vasodilator actions. These results indicate that oral pirbuterol should be included in the pharmacologic treatment of severe chronic congestive heart failure and may represent a significant therapeutic advance.

670 **Hemodynamic Effects of Intravenous Prenalterol in Severe Heart Failure**

PHILIP C. KIRLIN and BERTRAM PITT

The administration of intravenous prenalterol (a new catecholamine-like inotropic agent) to nine patients with chronic severe low output heart failure significantly improved their hemodynamic state as measured by increased left ventricular ejection fraction (to 26 ± 4 percent), decreased left ventricular filling pressure (to 21 ± 8 mm Hg), increased cardiac index (to 2.4 ± 0.6 liters/min per m^2) and increased left ventricular stroke work index (to 26 ± 8 g-m/m^2). The decrease in the abnormally elevated pulmonary vascular resistance after administration of this drug was comparable with similar changes noted with dobutamine. Significant adverse effects included increased ventricular ectopic beats in two patients and asymptomatic ventricular tachycardia in two patients. The combination of severe ischemic heart failure and previous digoxin therapy warrants particular caution in the administration of prenalterol.

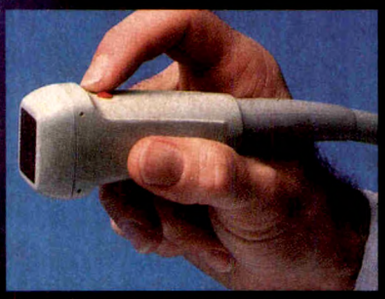
THE IMAGE QUALITY IS EVERYTHING YOU'D EXPECT FROM HEWLETT-PACKARD.

Compact, cart-mounted mobile system is ideal for the cardiology lab as well as coronary care units.

Now you can get a full-featured, real time, phased array, two-dimensional scanner that offers meaningful technological advances in almost every area.

It's the real time scanner for echocardiography from Hewlett-Packard. Incorporating a small 64-element array transducer, innovations in signal processing, microcomputer-based circuitry and a new digital scan converter, the HP system not only provides superior image quality, it does it at a price

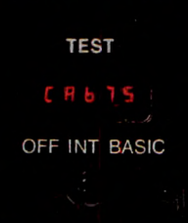


Small, lightweight, handheld transducer minitaped and replayed on standard video equipment.

that compares favorably to conventional mechanical scanners.

Superb resolution for accurate diagnosis.

The HP Ultrasound Imaging System provides extraordinarily high resolution images at all depths throughout the field of view. Its wide aperture, small electronic array transducer and automatic focusing technique give you extremely accurate images—even in areas near the transducer and deep in the body. And since the entire field of view is in focus at all times, you can see shallow as well as deep structures in the same picture. The compact, lightweight transducer fits in intercostal spaces and enhances the scanning of the heart.



Built-in self-test capability assures the operator that everything is functioning properly.

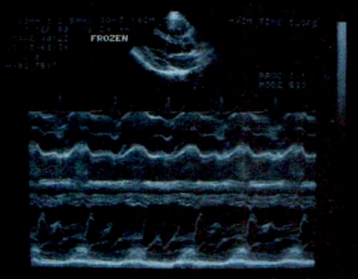
A new method of digital scan conversion eliminates radial scan lines, moiré patterns and blocky digital artifacts, and results in an accurate image. A total of 30 shades of gray can be processed, so small variations in tissue density can be distinguished.

Quantitative analysis on both the M-mode and two-dimensional image is accomplished by an electronic cursor.

The wide dynamic range of the system's circuitry produces a sharp image, while reducing background noise and clutter. The system's high-resolution, high-speed (twice the conventional TV rate) display gives you an easy-to-see

Simple, centralized controls for easy operation.

With the HP scanner, you not only get superior image quality, you get it quickly and easily. All major controls are logically located in one central area. You can scan patient after patient with a minimum of control adjustments. The HP scanner even provides a built-in self-test capability, so you know that everything is functioning properly.



M-mode is easily visualized on the same screen as the two-dimensional sector.

All this and more, for less.

While the HP scanner delivers exceptional image quality and easy operation, it doesn't compromise features. It offers quantitative analysis capabilities, ECG triggering, and "freeze-frame." You can view the sector scan and the M-mode display on the same screen simultaneously. In addition, the dual M-mode display lets you analyze two areas of the heart at the same time.

For more information on this full-featured, surprisingly affordable HP Model 77020A Ultrasound Imaging System for echocardiography, call your local Hewlett-Packard sales office, or write: Wayne Wager, Hewlett-Packard, 175 Wyman

676 **Ventricular Tachycardia: Prediction of Response to Oral Aprindine With Intravenous Aprindine**

BORIS STRASBERG, EDWIN PALILEO, DARREL PRECHEL, ROBERT BAUERNFEIND, STEVEN SWIRYN, CHRISTOPHER R. WYNDHAM, RAMESH C. DHINGRA, RICHARD KEHOE and KENNETH M. ROSEN

The intravenous administration of aprindine to 25 patients with ventricular tachycardia refractory to conventional antiarrhythmic agents helped to predict the subsequent response to oral aprindine. Eleven patients (43 percent) had conversion to sinus rhythm with intravenous aprindine and remained free of ventricular tachycardia during oral treatment with aprindine for a follow-up period of 2 to 38 months. It is unclear why patients with incessant ventricular tachycardia tended to respond whereas those with paroxysmal sustained ventricular tachycardia did not. Twelve patients manifested mild neurotoxicity, consisting primarily of mild tremor or mild ataxia, or both, after the oral dose of aprindine was established.

SEMINAR:

CARDIOVASCULAR FUNCTION IN RESPIRATORY FAILURE—I

Richard A. Matthay, MD and Lawrence D. H. Wood, MD, Guest Editors

683 **Introduction: The Functionally Integrated Cardiovascular-Pulmonary Unit**

RICHARD A. MATTHAY and LAWRENCE D. H. WOOD

686 **Contractile Mechanisms and Interaction of the Right and Left Ventricles**

KARL T. WEBER, JOSEPH S. JANICKI, SANJEEV SHROFF and ALFRED P. FISHMAN

This review of the physiologic behavior of the cardiopulmonary unit provides insight into the clinical recognition and management of the patient with respiratory failure. The cardiopulmonary unit consists of the right and left ventricles (two in-series pumps composed of cardiac muscle), which are mechanically coupled by the lungs. The factors controlling cardiac muscle shortening also regulate the pumping behavior of the ventricles. The interventricular septum, pericardium and intrathoracic pressure also influence the behavior of this system.

696 **Control of Cardiac Output by Systemic Vessels. Circulatory Adjustments to Acute and Chronic Respiratory Failure and the Effect of Therapeutic Interventions**

HOWARD S. GOLDBERG and JOHN RABSON

This review presents an integrated approach to circulatory function and its adjustments in patients with acute and chronic respiratory failure based on the following factors that influence venous return: (1) mean pressure in the systemic vasculature, (2) right atrial pressure, and (3) the resistance to venous return. Right atrial pressure depends on the contractile state of the right and left ventricles, the load on them, the presence or absence of pericardial effusion and alterations in pleural pressure with positive pressure ventilation. Diuretic drugs, cardiac glycosides, other inotropic or vasoactive drugs and positive pressure ventilation may affect the circulation by influencing the relation between the mean systemic pressure and right atrial pressure. For reasons presented in this review, cardiac glycosides may not be of value and the overly vigorous use of diuretic agents may even be potentially dangerous in the management of patients with cor pulmonale.

DIAGNOSTIC SHELF

703 **Observations on Spontaneous Termination of Atrioventricular Nodal Reentrant Tachycardia**

PEDRO BRUGADA, DAVID ROSS, FRITS W. H. M. BÄR, EDDY J. VANAGT, WILLEM R. M. DASSEN and HEIN J. J. WELLENS

These observations on the spontaneous termination of tachycardia during programmed electrical stimulation of the heart in two patients with atrioventricular nodal tachycardia emphasize how conduction over a third pathway connected to the reentry circuit can produce refractoriness in the reentry circuit and terminate the arrhythmia. This pathway was located extranodally in one patient and intranodally in the other. Present methods of investigation in the intact human heart are not yet refined enough to uncover most of these complex mechanisms.

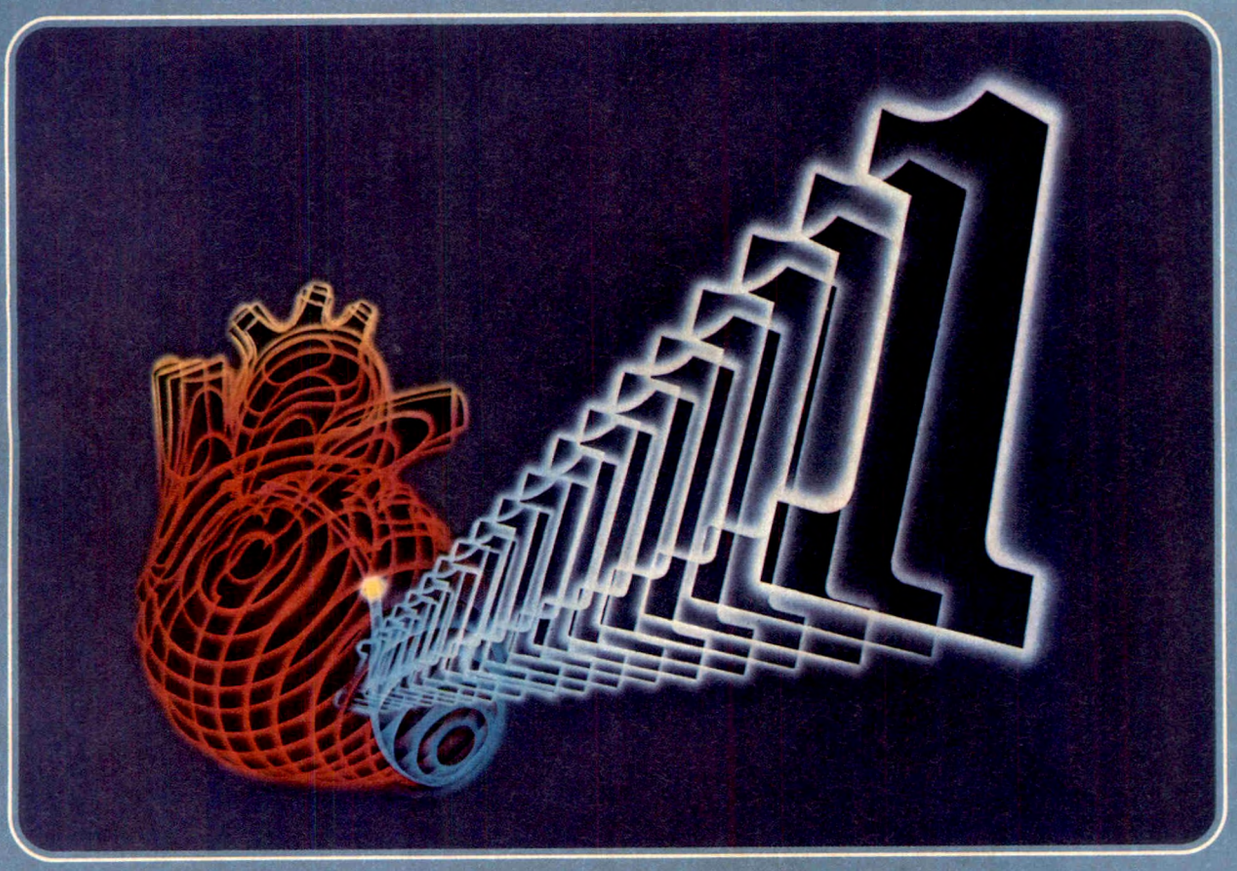
CORGARD®
nadolol tablets

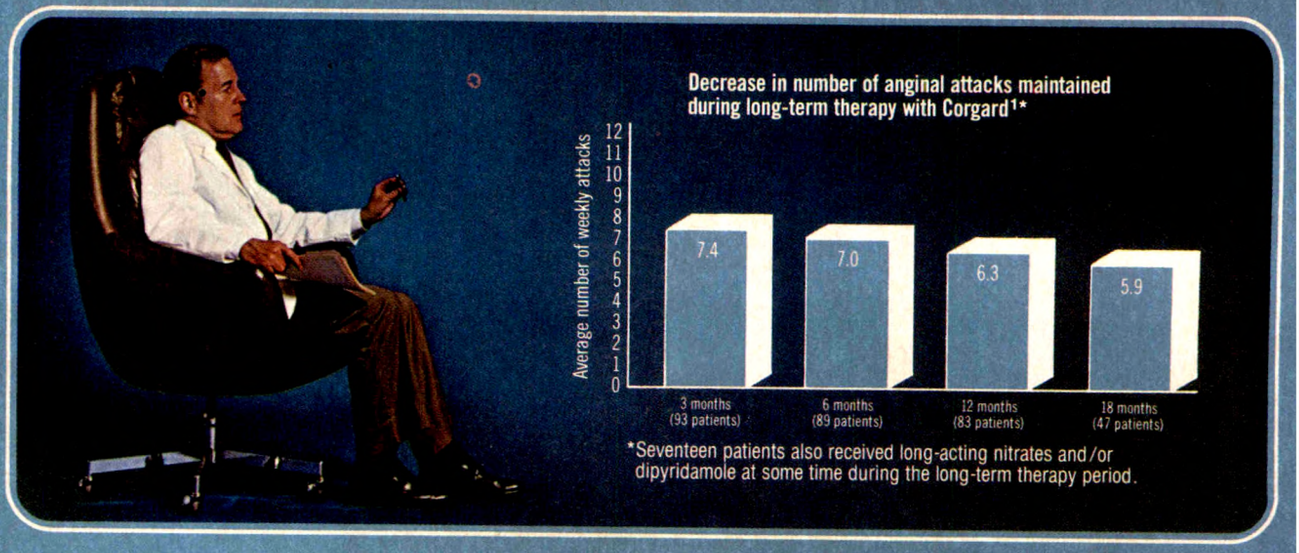


The first and only beta-blocker with once-a-day dosage

In the treatment of angina pectoris

SQUIBB

See last page of this advertisement for brief summary.



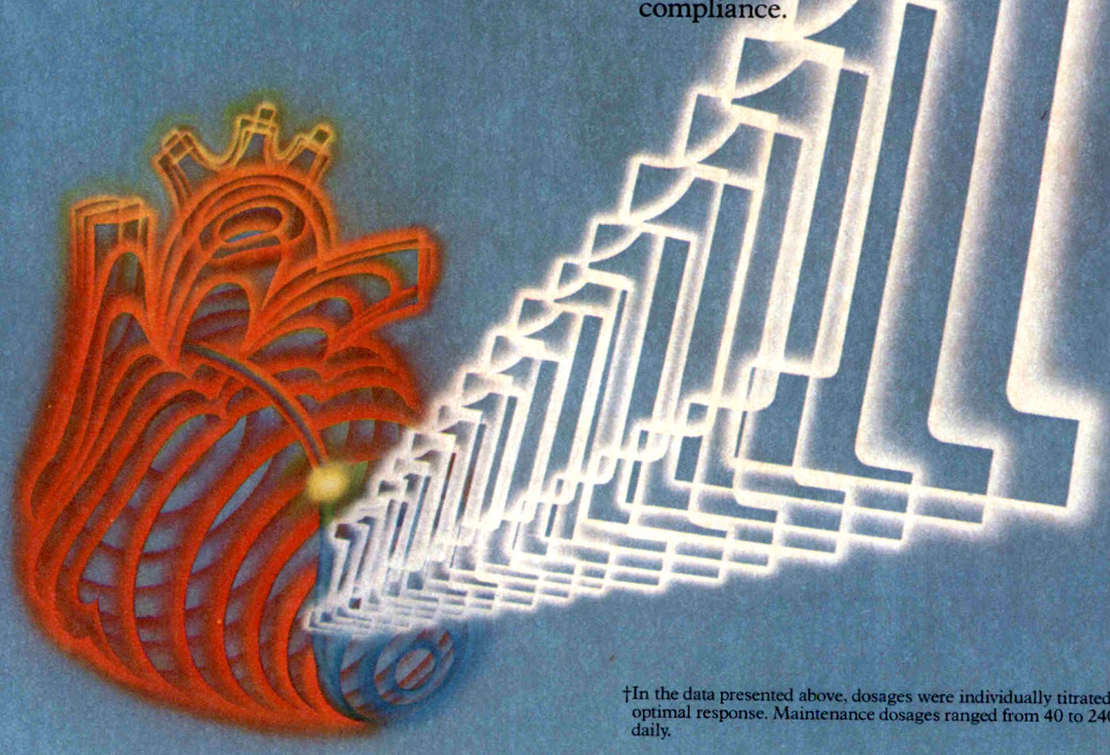
CORGARD® [nadolol tablets]:

Once-a-day, everyday, Corgard offers round-the-clock protection

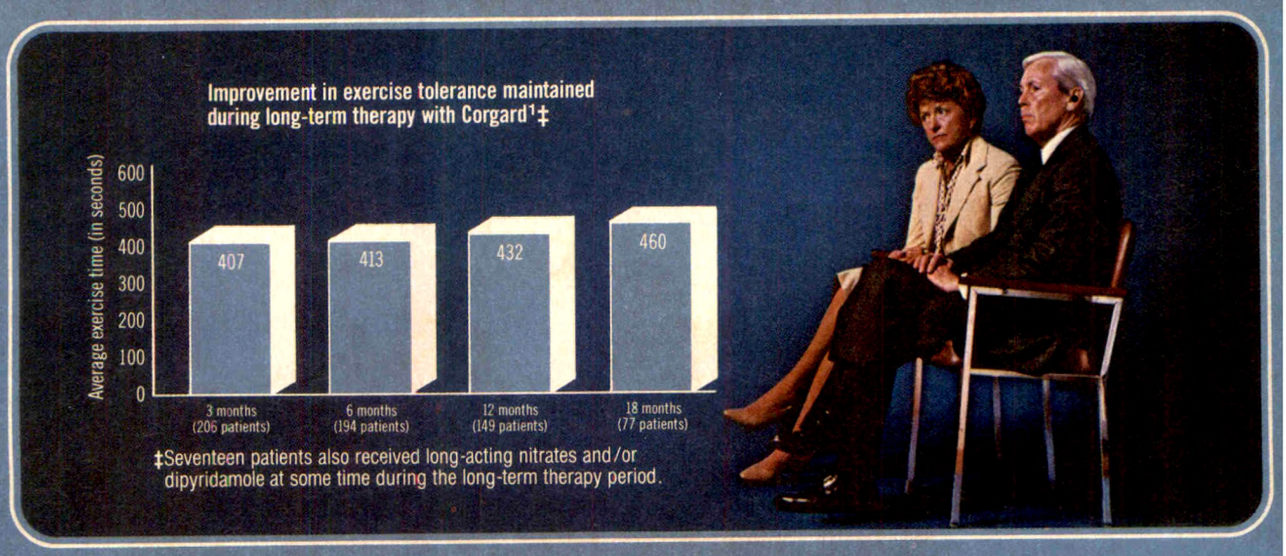
A single daily dose of Corgard offers prophylaxis in angina pectoris, helping to protect the patient all day and all night from painful attacks. And in extended clinical studies, the efficacy of Corgard — as demonstrated by a decreased rate of anginal attacks and an increase in exercise tolerance — was maintained.[1]

Once-a-day, everyday, Corgard decreases the frequency of anginal attacks

Corgard taken just once daily offers round-the-clock protection from angina pain. In one short-term study, Corgard, once a day, decreased the average number of anginal attacks per week in 115 patients with angina, from 13.6 pretherapy to 6.4 at the end of 14 weeks of therapy, a mean decrease of 59%.[1†] In 19% of the 115 patients, anginal attacks were completely eliminated. And the long half-life (20 to 24 hours) makes Corgard the once-a-day beta-blocker, promoting patient compliance.



†In the data presented above, dosages were individually titrated to achieve optimal response. Maintenance dosages ranged from 40 to 240 mg Corgard daily.



Effective control of angina pectoris

Once-a-day, everyday, Corgard increases exercise tolerance

Corgard allows the angina patient to do more. In 147 patients in the same short-term study as the one at left, Corgard, once a day, increased ergometry time by 25%, improving exercise tolerance from an average of 365 seconds pretherapy to 427 seconds at the end of 14 weeks of therapy.[1] In 21% of the 147 patients, the end point of exercise was fatigue rather than angina pain. And the single daily dose of Corgard can be taken at the patient's convenience, without regard to meals.

Once-a-day, everyday, Corgard decreases nitroglycerin usage[1]

Corgard blocks catecholamine influence on myocardial activity, decreases myocardial oxygen demand, and does not have a direct myocardial depressant effect.

CORGARD® TABLETS
Nadolol Tablets

DESCRIPTION: Corgard (nadolol) is a synthetic nonselective beta-adrenergic receptor blocking agent.

CONTRAINDICATIONS: Bronchial asthma, sinus bradycardia and greater than first degree conduction block, cardiogenic shock, and overt cardiac failure (see WARNINGS).

WARNINGS: Cardiac Failure—Sympathetic stimulation may be a vital component supporting circulatory function in congestive heart failure, and its inhibition by beta-blockade may precipitate more severe failure. Although beta-blockers should be avoided in overt congestive heart failure, if necessary, they can be used with caution in patients with a history of failure who are well-compensated, usually with digitalis and diuretics. Beta-adrenergic blocking agents do not abolish the inotropic action of digitalis on heart muscle. IN PATIENTS WITHOUT A HISTORY OF HEART FAILURE, continued use of beta-blockers can, in some cases, lead to cardiac failure; therefore, at first sign or symptom of heart failure, digitalize and/or give diuretics, and closely observe response, or discontinue nadolol (gradually if possible).

Exacerbation of Ischemic Heart Disease Following Abrupt Withdrawal — Hypersensitivity to catecholamines has been observed in patients withdrawn from beta-blocker therapy; exacerbation of angina and, in some cases, myocardial infarction have occurred after *abrupt* discontinuation of such therapy. When discontinuing chronic use of nadolol, particularly in patients with ischemic heart disease, gradually reduce dosage over a 1- to 2-week period and carefully monitor the patient. Reinstitute nadolol promptly (at least temporarily) and take other measures appropriate for management of unstable angina if angina markedly worsens or acute coronary insufficiency develops. Warn patients not to interrupt or discontinue therapy without physician's advice. Because coronary artery disease is common and may be unrecognized, it may be prudent not to discontinue nadolol therapy abruptly even in patients treated only for hypertension.

Nonallergic Bronchospasm (e.g., chronic bronchitis, emphysema) — PATIENTS WITH BRONCHOSPASTIC DISEASES SHOULD IN GENERAL NOT RECEIVE BETA-BLOCKERS. Administer nadolol with caution since it may block bronchodilation produced by endogenous or exogenous catecholamine stimulation of $beta_2$ receptors.

Major Surgery — Because beta-blockade impairs the ability of the heart to respond to reflex stimuli and may increase risks of general anesthesia and surgical procedures, it has generally been suggested that such therapy should be withdrawn several days prior to surgery. Recognition of the increased sensitivity to catecholamines of patients recently withdrawn from beta-blocker therapy, however, has made this recommendation controversial. If possible, withdraw beta-blockers well before surgery takes place. In emergency surgery, inform the anesthesiologist that the patient is on beta-blocker therapy. Use of beta-receptor agonists such as isoproterenol, dopamine, dobutamine, or levarterenol can reverse the effects of nadolol. Difficulty in restarting and maintaining the heart beat has also been reported with beta-adrenergic receptor blocking agents.

Diabetes and Hypoglycemia — Beta-adrenergic blockade may prevent the appearance of premonitory signs and symptoms (e.g., tachycardia and blood pressure changes) of acute hypoglycemia. This is especially important with labile diabetics. Beta-blockade also reduces release of insulin in response to hyperglycemia; therefore, it may be necessary to adjust dose of antidiabetic drugs.

Thyrotoxicosis — Beta-adrenergic blockade may mask certain clinical signs (e.g., tachycardia) of hyperthyroidism. To avoid abrupt withdrawal of beta-adrenergic blockade which might precipitate a thyroid storm, carefully manage patients suspected of developing thyrotoxicosis.

PRECAUTIONS: Impaired Hepatic or Renal Function — Use nadolol with caution in presence of either of these conditions (see DOSAGE AND ADMINISTRATION section of package insert).

Information for Patients — Warn patients, especially those with evidence of coronary artery insufficiency, against interruption or discontinuation of nadolol without physician's advice. Although cardiac failure rarely occurs in properly selected patients, advise patients being treated with beta-adrenergic blocking agents to consult physician at first sign or symptom of impending failure.

Drug Interactions — Catecholamine-depleting drugs (e.g., reserpine) may have an additive effect when given with beta-blocking agents. When treating patients with nadolol plus a catecholamine-depleting agent, carefully observe for evidence of hypotension and/or excessive bradycardia which may produce vertigo, syncope, or postural hypotension.

Carcinogenesis, Mutagenesis, Impairment of Fertility — In 1 to 2 years' oral toxicologic studies in mice, rats, and dogs, nadolol did not produce significant toxic effects. In 2-year oral carcinogenic studies in rats and mice, nadolol did not produce neoplastic, preneoplastic, or nonneoplastic pathologic lesions.

Pregnancy — In animal reproduction studies with nadolol, evidence of embryo- and fetotoxicity was found in rabbits (but not in rats or hamsters) at doses 5 to 10 times greater (on a mg/kg basis) than maximum indicated human dose; no teratogenic potential was seen in any of these species. There are no well-controlled studies in pregnant women; therefore, use nadolol in pregnant women only if potential benefit justifies potential risk to the fetus.

Nursing Mothers — It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, exercise caution when nadolol is administered to a nursing woman. Animal studies showed that nadolol is found in the milk of lactating rats.

Pediatric Use — Safety and effectiveness in children have not been established.

ADVERSE REACTIONS: Most adverse effects have been mild and transient and have rarely required nadolol withdrawal.

Cardiovascular — Bradycardia with heart rates of less than 60 beats per minute occurs commonly, and heart rates below 40 beats per minute and/or symptomatic bradycardia were seen in about 2 of 100 patients. Symptoms of peripheral vascular insufficiency, usually of the Raynaud type, have occurred in approximately 2 of 100 patients. Cardiac failure, hypotension, and rhythm/conduction disturbances have each occurred in about 1 of 100 patients. Single instances of first degree and third degree heart block have been reported; intensification of AV block is a known effect of beta-blockers (see also CONTRAINDICATIONS, WARNINGS, and PRECAUTIONS). **Central Nervous System** — Dizziness or fatigue reported in approximately 2 of 100 patients; paresthesias, sedation, and change in behavior reported in approximately 6 of 1000 patients. **Respiratory** — Bronchospasm reported in approximately 1 of 1000 patients (see CONTRAINDICATIONS and WARNINGS). **Gastrointestinal** — Nausea, diarrhea, abdominal discomfort, constipation, vomiting, indigestion, anorexia, bloating, and flatulence each reported in 1 to 5 of 1000 patients. **Miscellaneous** — Each of the following reported in 1 to 5 of 1000 patients: rash; pruritus; headache; dry mouth, eyes, or skin; impotence or decreased libido; facial swelling; weight gain; slurred speech; cough; nasal stuffiness; sweating; tinnitus; blurred vision. Although relationship to drug usage is not clear, sleep disturbances have been reported. The oculomucocutaneous syndrome associated with practolol has not been reported with nadolol.

Potential Adverse Effects: Although other adverse effects reported with other beta-adrenergic blocking agents have not been reported with nadolol, they should be considered potential adverse effects of nadolol. **Central Nervous System** — reversible mental depression progressing to catatonia; visual disturbances; hallucinations; an acute reversible syndrome characterized by disorientation for time and place; short-term memory loss, emotional lability with slightly clouded sensorium; decreased performance on neuropsychometrics. **Gastrointestinal** — mesenteric arterial thrombosis; ischemic colitis. **Hematologic** — agranulocytosis; thrombocytopenic or nonthrombocytopenic purpura. **Allergic** — fever combined with aching and sore throat; laryngospasm; respiratory distress. **Miscellaneous** — reversible alopecia; Peyronie's disease; erythematous rash.

OVERDOSAGE: Nadolol can be removed from the general circulation by hemodialysis. In addition to gastric lavage, employ the following measures as appropriate. In determining duration of corrective therapy, take note of long duration of effect of nadolol.

Excessive Bradycardia — Administer atropine (0.25 to 1.0 mg). If there is no response to vagal blockade, administer isoproterenol cautiously.

Cardiac Failure — Administer a digitalis glycoside and diuretic. It has been reported that glucagon may also be useful in this situation.

Hypotension — Administer vasopressors, e.g., epinephrine or levarterenol. (There is evidence that epinephrine may be the drug of choice.)

Bronchospasm — Administer a $beta_2$-stimulating agent and/or a theophylline derivative.

DOSAGE: For all patients, DOSAGE MUST BE INDIVIDUALIZED.

For **angina pectoris,** usual initial dose is 40 mg q.d.; gradually increase in 40 to 80 mg increments at 3 to 7 day intervals until optimum clinical response or pronounced slowing of the heart rate; usual maintenance dose is 80 to 240 mg q.d. (most patients respond to 1(mg or less daily). If treatment is to be discontinued, reduce dosage gradually over a period of 1 to 2 weeks (see WARNINGS).

For **hypertension,** usual initial dose is 40 mg q.d.; gradually increase in 40 to 80 mg increments until optimum blood pressure reduction is achieved; usual maintenance dose is 80 to 320 mg q.d. (rarely, doses up to 640 mg may be needed).

Patients with renal failure require adjustment in dosing interval — see package insert for dosage in these patients.

For full prescribing information, consult package insert.

HOW SUPPLIED: In scored tablets containing 40, 80, 120, or 160 mg nadolol per tablet in bottles of 100 and 1000 tablets and in Unimatic® single-dose packs of 100 tablets.

INTRODUCING THE VARIAN V-3400R

The Best Buy in Ultrasound Sector Scanning

New and improved features and a capacity for integrating future developments make the new Varian V-3400R phased array sector scanner the best buy in cardiac ultrasound imaging.

Superior Image Quality

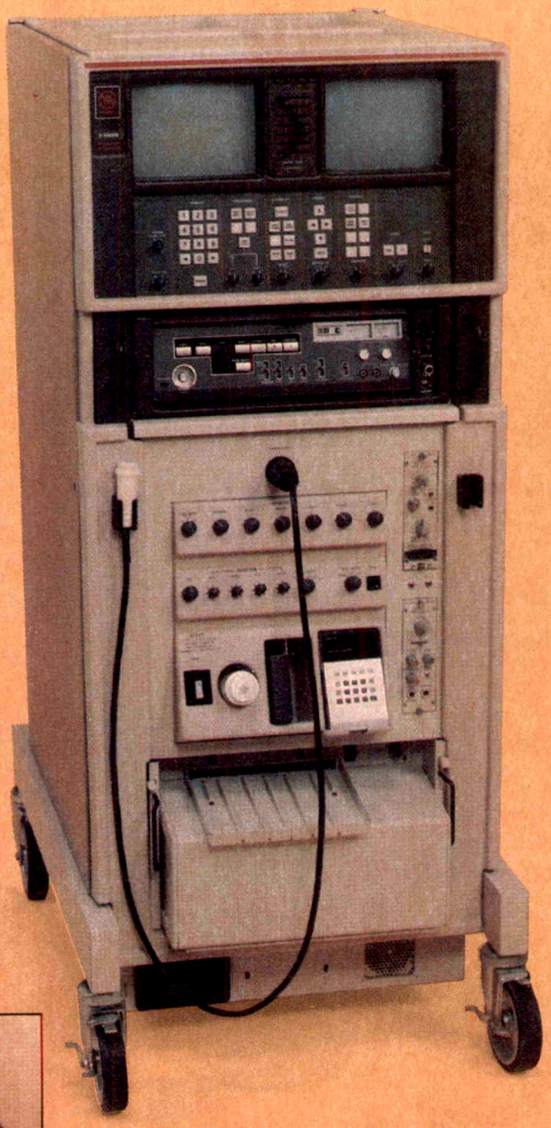
New image processing components combine with the smallest transducer available in real-time sector scanning.

Advanced Clinical Features

A more compact, mobile unit; sharper images with a new strip chart recorder; built-in videotape recorder with remote controls; display of up to four physiological channels; and a high-quality M-mode with new capabilities.

Powerful Image Processing

The widely accepted Varian Digital Scan Processor (DSP) with dual memory, now with improved software, provides grey-scale manipulation; variable image persistence; frame averaging; expanded freeze frame; and quantitation capabilities. **Also, evaluate data with the companion Image Analysis Center.**



Flexible, Upgradeable Design

Built-in capacity for integrating future Varian developments now in progress such as: Digital M-Mode, Dual-Phasing High-Resolution Image Processing, and Doppler.

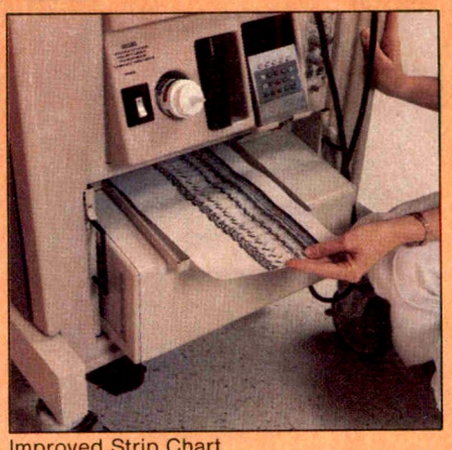
Ease of Control



Improved Strip Chart

Mobility

708 **Prolapsed Left Atrium Behind the Left Ventricular Posterior Wall: Two Dimensional Echocardiographic and Angiographic Features**

WILLIAM C. REEVES, THOMAS CIOTOLA, JOSEPH D. BABB, EDWARD BUONOCORE, DAVID LEAMAN with the technical assistance of EUGENE BEERS and LaDORA PAPICH

In three patients with a greatly enlarged left atrium resulting from rheumatic mitral valve disease, two dimensional echocardiography correctly detected portions of a huge left atrium that prolapsed behind the left ventricular posterior wall and mimicked an isolated posterior pericardial effusion on M mode echocardiography. In one patient left ventricular angiography suggested a ventricular septal defect or a false aneurysm of the left ventricle in the single plane right anterior oblique projection. For these reasons the authors urge the use of two dimensional echocardiography in the presence of a large left atrium to look for left atrial prolapse when isolated echo-free spaces are noted behind the left ventricular posterior wall on M mode echocardiography. All three patients underwent successful mitral valve replacement.

BETHESDA CONFERENCE REPORT

713 **Eleventh Bethesda Conference: Prevention of Coronary Heart Disease**

This Bethesda Conference focuses on the role of physician leadership in the prevention of coronary heart disease. The speakers reiterate the importance and potential value of weight control, dietary management, lowering of elevated blood pressure, cessation of cigarette smoking and avoidance of excessive alcohol consumption in improving the chances of avoiding clinical coronary artery disease. Changes in lifestyle and lifestyle-related risk factors have made a key contribution to the appreciable decline in mortality due to coronary artery disease. More is possible and needed.

Unlike diazepam® and chlordiazepoxide®
Ativan clearance is not delayed by Tagamet[1-3]
... a particularly striking and practical illustration of the fact that *all benzodiazepines are not alike.* Concomitant use of Tagamet has been shown to cause excessive accumulation and oversedation in patients taking diazepam.[1] No such interaction has been shown to occur with Ativan. Thus, with Ativan, there is less risk of drug accumulation leading to unwanted sedation in patients on Tagamet therapy.
In fact, Ativan has been given with a large number of widely prescribed cardiovascular and gastrointestinal medications without evidence of interaction. All benzodiazepines, however, produce additive effects when given with CNS depressants, such as barbiturates or alcohol.

with Tagamet®*

Other advantages of Ativan (lorazepam):

- Shorter half-life helps avoid excessive accumulation
- No active metabolites, less work for the liver
- B.I.D. dosage encourages compliance

Ativan® for (lorazepam) Anxiety

†Anxiety or tension associated with the stress of everyday life usually does not require treatment with an anxiolytic.

See important information on following page.

Wyeth Laboratories
Philadelphia, PA 19101

Brief Summary of Prescribing Information.

Indications and Usage: Management of anxiety disorders or short-term relief of symptoms of anxiety or anxiety associated with depressive symptoms. Anxiety or tension associated with stress of everyday life usually does not require treatment with an anxiolytic.

Effectiveness in long-term use, i.e., more than 4 months, has not been assessed by systematic clinical studies. Reassess periodically usefulness of the drug for the individual patient.

Contraindications: Known sensitivity to benzodiazepines or acute narrow-angle glaucoma.

Warnings: Not recommended in primary depressive disorders or psychoses. As with all CNS-acting drugs, warn patients not to operate machinery or motor vehicles, and of diminished tolerance for alcohol and other CNS depressants.

Physical and Psychological Dependence: Withdrawal symptoms like those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepines (including convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Addiction-prone individuals, e.g. drug addicts and alcoholics, should be under careful surveillance when on benzodiazepines because of their predisposition to habituation and dependence. Withdrawal symptoms have also been reported following abrupt discontinuance of benzodiazepines taken continuously at therapeutic levels for several months.

Precautions: In depression accompanying anxiety, consider possibility for suicide.

For elderly or debilitated patients, initial daily dosage should not exceed 2mg to avoid oversedation. Terminate dosage gradually since abrupt withdrawal of any antianxiety agent may result in symptoms like those being treated: anxiety, agitation, irritability, tension, insomnia and occasional convulsions. Observe usual precautions with impaired renal or hepatic function. Where gastrointestinal or cardiovascular disorders coexist with anxiety, note that lorazepam has not been shown of significant benefit in treating gastrointestinal or cardiovascular component. Esophageal dilation occurred in rats treated with lorazepam for more than 1 year at 6mg/kg/day. No effect dose was 1.25mg/kg/day (about 6 times maximum human therapeutic dose of 10mg/day). Effect was reversible only when treatment was withdrawn within 2 months of first observation. Clinical significance is unknown; but use of lorazepam for prolonged periods and in geriatrics requires caution and frequent monitoring for symptoms of upper G.I. disease. Safety and effectiveness in children under 12 years have not been established.

ESSENTIAL LABORATORY TESTS: Some patients have developed leukopenia; some have had elevations of LDH. As with other benzodiazepines, periodic blood counts and liver function tests are recommended during long-term therapy.

CLINICALLY SIGNIFICANT DRUG INTERACTIONS: Benzodiazepines produce CNS depressant effects when administered with such medications as barbiturates or alcohol.

CARCINOGENESIS AND MUTAGENESIS: No evidence of carcinogenic potential emerged in rats during an 18-month study. No studies regarding mutagenesis have been performed.

PREGNANCY: Reproductive studies were performed in mice, rats, and 2 strains of rabbits. Occasional anomalies (reduction of tarsals, tibia, metatarsals, malrotated limbs, gastroschisis, malformed skull and microphthalmia) were seen in drug-treated rabbits without relationship to dosage. Although all these anomalies were not present in the concurrent control group, they have been reported to occur randomly in historical controls. At 40mg/kg and higher, there was evidence of fetal resorption and increased fetal loss in rabbits which was not seen at lower doses. Clinical significance of these findings is not known. However, increased risk of congenital malformations associated with use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during first trimester of pregnancy has been suggested in several studies. Because use of these drugs is rarely a matter of urgency, use of lorazepam during this period should almost always be avoided. Possibility that a woman of child-bearing potential may be pregnant at institution of therapy should be considered. Advise patients if they become pregnant to communicate with their physician about desirability of discontinuing the drug. In humans, blood levels from umbilical cord blood indicate placental transfer of lorazepam and its glucuronide.

NURSING MOTHERS: It is not known if oral lorazepam is excreted in human milk like other benzodiazepines. As a general rule, nursing should not be undertaken while on a drug since many drugs are excreted in milk.

Adverse Reactions, if they occur, are usually observed at beginning of therapy and generally disappear on continued medication or on decreasing dose. In a sample of about 3,500 anxious patients, most frequent adverse reaction is sedation (15.9%), followed by dizziness (6.9%), weakness (4.2%) and unsteadiness (3.4%). Less frequent are disorientation, depression, nausea, change in appetite, headache, sleep disturbance, agitation, dermatological symptoms, eye function disturbance, various gastrointestinal symptoms and autonomic manifestations. Incidence of sedation and unsteadiness increased with age. Small decreases in blood pressure have been noted but are not clinically significant, probably being related to relief of anxiety.

Overdosage: In management of overdosage with any drug, bear in mind multiple agents may have been taken. Manifestations of overdosage include somnolence, confusion and coma. Induce vomiting and/or undertake gastric lavage followed by general supportive care, monitoring vital signs and close observation. Hypotension, though unlikely, usually may be controlled with Levarterenol Bitartrate Injection U.S.P. Usefulness of dialysis has not been determined.

Ativan® (IV) for (lorazepam) Anxiety

Dosage: **Individualize for maximum beneficial effects. Increase dose gradually when needed, giving higher evening dose before increasing daytime doses. Anxiety, usually 2-3mg/day given b.i.d. or t.i.d.; dosage may vary from 1 to 10mg/day in divided doses. For elderly or debilitated, initially 1-2mg/day; insomnia due to anxiety or transient situational stress, 2-4mg h.s.**

How Supplied: **0.5, 1.0 and 2.0mg tablets.**

Announcing the comprehensive study of...the most fascinating syndrome in Cardiology...

THE PRE-EXCITATION SYNDROME: FACTS AND THEORIES

Libi Sherf, MD, FACC
Assoc. Professor of Cardiology, Heart Institute, Chaim Sheba Medical Cente Tel Hashomer, University of Tel Aviv—Sackler School of Medicine, and Visiti Assoc. Professor, Dept. of Medicine, University of Alabama.

Henry N. Neufeld, MD, FACC
Professor of Medicine and Chaim Sheba Professor of Cardiology, Chief, Heart Institute, Chaim Sheba Medical Center, Tel Hashomer, University of Tel Aviv—Sackler School of Medicine.

Every cardiologist, internist, pediatrician, surgeon—indeed *every physician*—should have a good basic knowledge of the Pre-excitation Syndrome. Here are just a few reasons wl this is so essential:

- ☐ ⅓ of all pre-excitation cases are misdiagnosed.
- ☐ 5% to 10% of all tachycardias in adults are produced by pre-excitation.
- ☐ In ½ of all infants under 10 months of age with life-threatening tachycardias, the tachycardias are actually secondary to pre-excitation.
- ☐ ⅓ to ½ of all children with pre-excitation have an additional heart disease.

Starting with Wolff, Parkinson and White's classic paper, thi book gives a comprehensive summary of all important facts of pre-excitation, plus the authors' personal experiences of follow-up studies of patients through many decades. It also brings a broad view of the literature and discusses the different structural and physiological aspects which form the pathomechanism of pre-excitation.

"What is offered richly in this book is a methodical and comprehensive analysis of virtually all currently available knowledge on the subject. This is done with an admirable even-handedness, dealing objectively with all viewpoints but at the same time evaluating relative strengths and weaknesses of each observation and hypothesis. There is brought a wisdc here which only time and experience can provide. The encyclopedic references alone would make the book invaluable to anyone seriously interested in the Wolff-Parkinson-White syndrome. But when knowledgeable discussion and personal observations are added, it is genuinely a monumental contribution to clinical cardiology and cardiac electrophysiology."

Thomas N. James, MD
The Mary Gertrude Waters Professor of Cardiology and Chairman the Department of Medicine, The University of Alabama in Birmin ham, and Physician-in-Chief, University of Alabama Hospitals.

LANOXIN®
(DIGOXIN)
ELIXIR PEDIATRIC
50 mcg (0.05 mg) per cc

INDICATIONS:

1. Congestive heart failure: Congestive heart failure, all degrees, is the primary indication. The increased cardiac output due to digoxin results in diuresis and general amelioration of the disturbances characteristic of right (venous congestion, edema) and left (dyspnea, orthopnea, cardiac asthma) heart failure.

Digoxin, generally, is most effective in "low output" failure and less effective in "high output" (bronchopulmonary insufficiency, infection, hyperthyroidism) heart failure.

Digoxin should be continued after heart failure is abolished unless some known precipitating factor is corrected.

2. Atrial fibrillation: Atrial fibrillation, especially when the ventricular rate is elevated. Digoxin rapidly reduces ventricular rates and eliminates the pulse deficit. Palpitation, precordial distress or weakness are relieved and any concomitant congestive failure ameliorated. Digoxin should be continued in doses necessary to maintain the desired ventricular rate and other clinical effects.

3. Atrial flutter: Digoxin slows the heart and regular sinus rhythm may appear. Frequently the flutter is converted to atrial fibrillation with a slow ventricular rate. Stopping digoxin at this point may be followed by restoration of sinus rhythm, especially if the flutter was of the paroxysmal type. It is preferable, however, to continue digoxin if failure ensues or if atrial flutter is a frequent occurrence.

4. Paroxysmal atrial tachycardia: Oral digoxin may be used, especially if the condition is resistant to lesser measures. Depending on the urgency, a more rapid acting parenteral preparation may be preferable to initiate digitalization, although if heart failure has ensued or paroxysms recur frequently, digoxin should be maintained by oral administration.

Digoxin is not indicated in sinus tachycardia unless due to heart failure.

5. Cardiogenic shock: The drug is often employed, especially when the condition is accompanied by pulmonary edema. Digoxin seems to affect adversely shock due to septicemia from gram-negative bacteria.

CONTRAINDICATIONS: The presence of toxic effects (see ADVERSE REACTIONS section) induced by any digitalis preparation is a contraindication to all of the glycosides.

Allergy, though rare, does occur. It may not extend to all preparations, and another may be tried.

Ventricular fibrillation.

WARNINGS:

> Digitalis alone or with other drugs has been promoted for use in the treatment of obesity. This use of digoxin or other digitalis glycosides is unwarranted. Moreover, since they may cause potentially fatal arrhythmias or other adverse effects, the use of these drugs in the treatment of obesity is dangerous.

Many of the arrhythmias for which digoxin is advised closely resemble those reflecting digoxin intoxication. If the possibility of digoxin intoxication cannot be excluded, cardiac glycosides should be temporarily withheld if permitted by the clinical situation.

The patient with congestive heart failure may complain of nausea and vomiting. These symptoms may also be indications of digoxin intoxication. A clinical determination of the cause of these symptoms must be attempted before further drug administration.

Patients with renal insufficiency require smaller than usual doses of digoxin. Newborn infants display considerable variability in their tolerance to digoxin, depending on their degree of maturity.

Premature and immature infants are particularly sensitive, and dosage must be reduced and digitalization should be even more individualized and cautiously approached than in more mature infants. Impaired renal function must also be carefully taken into consideration.

Congestive heart failure accompanying acute glomerulonephritis requires extreme care in digitalization. A relatively low total dose administered in divided doses and concomitant use of antihypertensive drugs has been recommended. ECG monitoring is essential. Digoxin should be discontinued as soon as possible.

Patients with idiopathic hypertrophic subaortic stenosis must be managed extremely carefully. Unless cardiac failure is severe, it is doubtful whether digoxin should be employed.

Patients with rheumatic carditis, especially when severe, are unusually sensitive to digoxin and prone to disturbances of rhythm. If heart failure develops, digitalization may be initiated with relatively low doses; then it can be cautiously increased until a beneficial effect is obtained. If a therapeutic trial does not result in improvement, the drug should be considered ineffective and be discontinued.

Note: Digitalis glycosides are an important cause of accidental poisoning in children.

PRECAUTIONS: Atrial arrhythmias associated with hypermetabolic states are particularly resistant to digoxin treatment. Care must be taken to avoid digoxin toxicity if digoxin is used to help the arrhythmia.

Digoxin is not indicated for the treatment of ventricular tachycardia unless congestive heart failure supervenes after a protracted episode not itself due to digoxin.

Potassium depletion sensitizes the myocardium to digoxin and toxicity may develop even with usual dosage. Hypokalemia may also alter the rate of onset and intensity of the positive inotropic effect of digoxin. Therefore, it is desirable to maintain normal serum potassium levels in patients being treated with digoxin.

Potassium wastage may result from diuretic or corticosteroid therapy, hemodialysis, and from suction of gastrointestinal secretions. It may accompany malnutrition, diarrhea, prolonged vomiting, old age, and long-standing congestive heart failure. In general, rapid changes in serum potassium or other electrolytes are to be avoided, and intravenous treatment with potassium should be reserved only for special circumstances as described below (see TREATMENT OF ARRHYTHMIAS PRODUCED BY OVERDOSAGES section).

Patients with acute myocardial infarction, severe pulmonary disease, or far advanced heart failure may be more sensitive to digoxin and more prone to disturbances of rhythm.

Calcium affects contractility and excitability of the heart in a manner similar to that of digoxin. Calcium may produce serious arrhythmias in digitalized patients.

In myxedema, the digoxin requirements are less because excretion rate is decreased and blood levels are significantly higher.

In incomplete A-V block, especially in patients subject to Stokes-Adams attacks, advanced or complete heart block may develop if digoxin is given. Heart failure in these patients can usually be controlled by other measures and by increasing the heart rate.

Patients with chronic constrictive pericarditis may respond unfavorably to digoxin.

Patients with idiopathic hypertrophic subaortic stenosis must be managed extremely carefully. Unless cardiac failure is severe, it is doubtful whether digoxin should be employed.

Renal insufficiency delays the excretion of digoxin and dosage must be adjusted accordingly in patients with renal disease. Note: This applies also to potassium administration should it become necessary.

Electrical conversion of arrhythmias may require reduction of digoxin dosage.

Dosage must be carefully titrated and differences in the bioavailability of parenteral preparations, elixirs, and tablets should be taken into account when switching patients from one preparation to another.

Electrocardiographic monitoring may be necessary to avoid intoxication.

Premonitory signs of toxicity in the newborn are undue slowing of the sinus rate, sinoatrial arrest, and prolongation of PR interval.

ADVERSE REACTIONS:

Gynecomastia: Uncommon.

Overdose or toxic effects in adults:

Gastrointestinal: Anorexia, nausea, vomiting, diarrhea are the most common early symptoms of overdosages in the adult (but rarely conspicuous in infants). Uncontrolled heart failure may also produce such symptoms.

Central nervous system: Visual disturbances (blurred vision, yellow vision), headache, weakness, apathy.

Cardiac disturbances (arrhythmias): Ventricular premature beats are the most common, except in infants and young children. Paroxysmal and nonparoxysmal nodal rhythms, atrioventricular (interference) dissociation and paroxysmal atrial tachycardia (PAT) with block are also common arrhythmias due to digoxin overdosage.

Conduction disturbances: Excessive slowing of the pulse is a clinical sign of digoxin overdosage. Atrioventricular block of increasing degree may proceed to complete heart block. Note: The electrocardiogram is fundamental in determining the presence and nature of these cardiac toxic disturbances. Digoxin may also induce other changes (as of the ST segment), but these provide no measure of the degree of digitalization.

Overdose or toxic effects in children:

Toxic signs differ from the adult in a number of respects. Cardiac arrhythmias are the more reliable and frequent signs of toxicity.

Vomiting and diarrhea, neurologic and visual disturbances are rare as initial signs.

Premature ventricular systoles are rarely seen; nodal and atrial systoles are more frequent.

Atrial arrhythmias, atrial ectopic rhythms, and paroxysmal atrial tachycardia with A-V block particularly are more common manifestations of toxicity in children.

Ventricular arrhythmias are rare.

TREATMENT OF ARRHYTHMIAS PRODUCED BY OVERDOSAGE: Digoxin should be discontinued until all signs of toxicity are abolished. Discontinuation may be all that is necessary if toxic manifestations are not severe and appear after the time for peak effect of the drug.

Potassium salts are commonly used. Potassium chloride in divided oral doses totaling 4-6 grams for adults (see PEDIATRIC INFORMATION section for pediatric dosage) may be given provided renal function is adequate.

When correction of the arrhythmia is urgent and the serum potassium level is low or normal, potassium should be administered intravenously in a solution of 5 percent dextrose in water. A total of 40-100 milliequivalents (30 milliequivalents per 500 milliliters) is given at the rate of 20 milliequivalents per hour unless limited by pain due to local irritation.

Additional amounts may be given if the arrhythmia is uncontrolled and the potassium well tolerated.

Continuous electrocardiographic monitoring should be performed to watch for any evidence of potassium toxicity, e.g., peaking of T waves, and to observe the effect on the arrhythmia so that the infusion may be promptly stopped when the desired effect is achieved.

Caution: Potassium should not be used and may be dangerous for severe or complete heart block due to digoxin and not related to any tachycardia.

Other agents that have been approved for the treatment of digoxin intoxication include procainamide, lidocaine, and propranolol.

Pediatric Information: (See adult section for other recommendations for the treatment of arrhythmias produced by overdosages and for additional recommendations and cautions regarding the use of potassium.) Potassium preparations may be given orally in divided doses totaling 1-1.5 milliequivalents/kilogram (1 gram K contains 13.4 milliequivalents). When correction of the arrhythmia is urgent, approximately 0.5 milliequivalents/kilogram of potassium per hour may be given, with careful electrocardiographic monitoring, as a solution of 20 milliequivalents or less for 500 milliliters in 5 percent dextrose in water. The total dose should generally not exceed 2 milliequivalents of potassium/kilogram.

DOSAGE AND ADMINISTRATION: Oral digoxin is administered slowly or rapidly as required until the desired therapeutic effect is obtained without symptoms of overdosage. The amount can be predicted approximately from the lean body mass of the patient with allowances made for excretion during the time taken to induce digitalization.

Subsequent maintenance dosage is also determined tentatively by the amount necessary to sustain the desired therapeutic effect.

Recommended dosages are practical average figures that may require considerable modification as dictated by individual sensitivity or associated conditions. Diminished renal function is the most important factor requiring modification of recommended or average doses. (See WARNINGS and PRECAUTIONS sections.)

The average amount of digoxin that patients must accumulate to be digitalized with digoxin tablets is 1.0-1.5 milligrams. Digitalization may be accomplished by any of several approaches that vary in dosage and frequency of administration, but reach the same endpoint in terms of total amount accumulated.

In previously undigitalized patients, a single loading dose of 0.5-0.75 milligram orally usually produces a detectable effect in 1-2 hours that becomes maximal in 6-8 hours. Additional doses of 0.25-0.5 milligram may be given cautiously at 6-8 hour intervals to full digitalization.

In previously undigitalized patients, institution of daily maintenance therapy (0.125-0.5 milligram, see next paragraph) without a loading dose results in development of steady-state plateau concentrations in about 7 days in patients with normal renal function.

The average daily oral maintenance dose is 0.125-0.5 milligram, usually 0.25 milligram. In the elderly patient, 0.125-0.25 milligram should be considered the average maintenance dose.

In patients with renal impairment, digoxin excretion is impaired and serum half-life is prolonged. Digitalizing and maintenance doses are lower than those recommended for patients with normal renal functions. Signs of digoxin toxicity develop sooner in patients with renal impairment, and it takes longer for toxic signs and symptoms to disappear. Because of the prolonged half-life, a longer period of time is required to achieve an initial or new steady-state plateau in patients with renal impairment than in patients with normal renal function.

It cannot be overemphasized that the values given are averages and substantial individual variation can be expected.

Children: Digitalization must be individualized. Generally, premature and immature infants are particularly sensitive, requiring reduced dosage that must be determined by careful titration.

Oral Dosage. Beyond the immediate newborn period, children require proportionally greater doses than adults on the basis of body weight or surface area. The recommended oral digitalizing dosages in children with normal renal function are:

Newborn infants (normal), up to 1 month, require 40-60 micrograms (mcg)/kilogram.

Infants, 1 month to 2 years, require approximately 60-80 micrograms (mcg)/kilogram.

Children, 2 years to 10 years, require 40-60 micrograms (mcg)/kilogram.

Children, over 10 years of age, require adult dosages in proportion to their body weight.

Maintenance therapy is 20-30 percent of the digitalizing dose administered each day.

Long term use of digoxin is indicated in almost all infants who have been digitalized for acute congestive heart failure unless the cause is transient. Many favor maintaining digoxin until at least 2 years of age in all infants with paroxysmal atrial tachycardia or in those who show either definite or latent failure.

Many children with severe inoperable congenital defects need digoxin throughout childhood and often for life.

CLINICAL STUDIES

The Natural History of Idiopathic Dilated Cardiomyopathy

VALENTIN FUSTER, MD, FACC

ABDUL J. TAJIK, MD, FACC
ROBERT O. BRANDENBURG, MD, FACC
ROBERT L. FRYE, MD, FACC

Rochester, Minnesota

Between 1960 and 1973, a total of 104 patients at the Mayo Clinic had a diagnosis of idiopathic dilated cardiomyopathy on the basis of clinical and angiographic criteria; these patients were followed up for 6 to 20 years. Twenty-one percent of the patients had a history of excessive consumption of alcohol, 20 percent had had a severe influenza-like syndrome within 60 days before the appearance of cardiac manifestations and 8 percent had had rheumatic fever without involvement of cardiac valves several years before; thus, possible etiologic risk factors of infectious-immunologic type may be important. Eighty patients (77 percent) had an accelerated course to death, with two thirds of the deaths occurring within the first 2 years. Twenty-four patients (23 percent) survived, and 18 of them had clinical improvement and a normal or reduced heart size. Univariate analysis at the time of diagnosis revealed three factors that were highly predictive ($p < 0.01$) of the clinical course: age, cardiothoracic ratio on chest roentgenography and cardiac index. Systemic emboli occurred in 18 percent of the patients who did not receive anticoagulant therapy and in none of those who did; thus, anticoagulant agents should probably be prescribed unless their use is contraindicated.

Recognition of the protean manifestations of cardiomyopathy has led to the modification of previous definitions. Currently, cardiomyopathies are defined as "heart muscle diseases of unknown cause." [1] On the basis of the morphologic and functional abnormalities, Goodwin[2] classified cardiomyopathies into three major groups: congestive, hypertrophic and restrictive or obliterative.

The term *congestive cardiomyopathy* is derived from the common late clinical manifestation of congestive cardiac failure. However, dilatation of the cardiac chambers (particularly the left ventricle) is an earlier and predominant feature, and for this reason the term *dilated cardiomyopathy* is preferred.[1] Idiopathic dilated cardiomyopathy remains a challenge because the cause is unknown, the natural history is ill defined, and the response to therapy is generally unsatisfactory. A need for new preventive and therapeutic approaches to this commonly fatal disease is obvious. Identification of the patients most likely to benefit from newer therapeutic advances requires an understanding of the natural history of the disease. Accordingly, this long-term retrospective follow-up study was undertaken.

From the Division of Cardiovascular Diseases and Internal Medicine, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. Manuscript received August 6, 1980; revised manuscript received October 6, 1980, accepted October 9, 1980.

Methods

Study patients: The study group comprised 104 patients (64 men and 40 women; median age 49 years) with dilated cardiomyopathy who were seen consecutively at the Mayo Clinic between January 1960 and December 1973. All 104 patients were followed up for a minimum of 6 years or until death, if it occurred in less than 6 years. The median follow-up period was 11 years and the longest was 20 years. The initial clinical history of the 104 patients was recorded by at least two physicians, and the clinical records were carefully examined in retrospect by two of us. Follow-up information was obtained in all patients from repeated examinations at the Mayo Clinic (91 percent of patients) and from responses to telephone calls to the patients or relatives and to the referring physicians. Although the study originally included 125 patients, the 21 patients living outside the United States were excluded because complete information was difficult to obtain. At the time of entry into the study, all patients had a diagnosis of dilated cardiomyopathy that fulfilled strict clinical, angiographic and etiologic criteria, as described in the following sections.

Clinical criteria: At the time of entry into the study, each of the 104 patients had two or more of the following four clinical features: (1) symptoms and signs of left or right heart failure, or both; (2) roentgenographic evidence of cardiomegaly and a cardiothoracic ratio greater than 0.50; (3) an electrocardiographic abnormality in the form of left ventricular conduction delay (with a wide QRS complex greater than 0.08 second), first degree atrioventricular block (P-R interval greater than 0.19 second), intraatrial conduction delay (P wave greater than 0.10 second), left ventricular hypertrophy (S wave in lead V_1 or V_2 plus R wave in lead V_5 or V_6 greater than 40 mm) or atrial flutter or fibrillation; and (4) a history of systemic emboli since the time of initial manifestation of the disease. Patients with clinical evidence of underlying coronary artery disease, systemic hypertension (hypertension subsequently developed in only four patients), cor pulmonale, valvular heart disease, predominant pericardial disease, and insulin-dependent diabetes or systemic disease involving the heart muscle were excluded from the study.

In all patients we recorded (1) the period between the initial clinical manifestation and the clinical and angiographic diagnosis of dilated cardiomyopathy or entry into the study, (2) all clinical features at the time of the diagnosis or entry into the study, and (3) all clinical features during the total follow-up period, including the exact period during which anticoagulant agents and other therapeutic interventions were used.

Hemodynamic and angiographic criteria: At the time of entry into the study, all 104 patients underwent left ventricular hemodynamic and angiographic study and 46 patients also had selective coronary cineangiography.[3] At the time of catheterization, most patients (85 percent) were taking digoxin or diuretic drugs, or both. Catheterization procedures included (1) measurement of left ventricular end-diastolic pressure and cardiac index, (2) left ventriculography, and (3) coronary cineangiography. When these studies were done (1960 to 1973), left ventricular ejection fraction could not be accurately obtained because simultaneous biplane views were not available; in addition, the 6 inch (15.24 cm) frame used at that time was often too small to assess the larger ventricles.

The cardiac index was determined[4] with use of the oxymetric principle of Fick in 63 patients, the Peterson-Wood indicator-dilution technique with indocyanine green in 21 patients and with both methods in 20 patients; this procedure provided paired results that did not differ statistically.

Left ventriculography was performed in the 45° right anterior oblique projection. The left ventricular anterior surface (which included the anterobasal, anterolateral and apical segments) and the inferior surface (which included the diaphragmatic and posterobasal segments) were analyzed for distinct types of abnormal contraction, as described by Herman et al.[5] As required for inclusion in the study, in all patients the left ventricular angiogram revealed a dilated left ventricle and a diffuse, global decrease in amplitude of contraction, a feature that contrasts with the segmental wall motion abnormalities of coronary heart disease.

Coronary cineangiograms were performed in right and left oblique and left lateral projections, and the degree of obstruction of a vessel was derived from estimates of the width of the respective vessel in its normal portion compared with that of its most diseased portion, the latter being expressed as a percent of the former. Patients were excluded from the study if they had an obstruction of at least 50 percent of luminal diameter in one of the four major coronary arteries (right coronary, left anterior descending, left circumflex and left main coronary) or of their main branches. On the basis of these criteria, the 46 patients who had selective coronary cineangiography were free of appreciable coronary artery disease; moreover, 14 other patients of the group who had postmortem examination were also free of appreciable coronary artery disease. Thus, as required for inclusion in the study, none of the 104 patients had clinical evidence of appreciable coronary artery disease, and this was confirmed in 60 of the patients by coronary cineangiography or autopsy; this group of 60 also included the 8 who had abnormal Q waves in the electrocardiogram that were otherwise atypical of myocardial infarction.

Etiologic criteria: Because cardiomyopathies are defined as diseases of the cardiac muscle of unknown cause, we excluded all patients with specific disorders involving heart muscle as part of a general systemic disease.[1,6] Moreover, in the 39 autopsy cases, neither gross pathologic study nor light microscopy offered any clue about cause.

In an attempt to determine possible risk factors that might disclose the underlying cardiomyopathy or contribute to its development, we computed and analyzed the following factors: (1) 52 professional and possible environmental factors (Hollingshead Occupational and Educational Scales Code, U.S. Federal Government, 1958) (patients living outside the United States were excluded from the study); (2) excessive consumption of alcohol, defined as a daily intake of at least 8 ounces of hard liquor or 2 quarts of beer for the preceding 10 years (no patient in the study had consumed excessive amounts of wine, that is, more than 1 quart daily); (3) severe influenza-like syndrome, associated or unassociated with pneumonitis, occurring 2 to 8 weeks before the first manifestation of cardiomyopathy; (4) clinical evidence of rheumatic fever[7] without apparent cardiac involvement, occurring several years before the first manifestation of the cardiomyopathy; (5) first manifestation of cardiomyopathy within 6 weeks after childbirth; and (6) family history, defined as documented dilated cardiomyopathy in at least one first degree relative.

Statistics: Significance of univariate analysis of prognostic factors was tested with Student's t test or the chi-square test. Stepwise linear discriminant function analysis was carried out according to the BMD P7M computer program of the Health Sciences Computing Facility, University of California, Los Angeles, California.

Results

Clinical and Hemodynamic Features

Clinical manifestations: The median period between the initial clinical manifestation and the clinical and angiographic diagnosis of dilated cardiomyopathy or entry into the study was 1.3 years. In decreasing order

TABLE I.

Clinical Features

	At Diagnosis (%)	At Follow-Up (%)
Cardiomegaly	87	89
Electrocardiographic abnormality	80	87
Left ventricular conduction delay	36	51
Atrial flutter or fibrillation	19	23
Intraatrial conduction delay	17	25
Left ventricular hypertrophy	14	7
First degree atrioventricular block	11	39
Heart failure	73	96
Systemic emboli	4	18

of frequency, the clinical manifestations at the time of diagnosis or entry into the study (Table I) were roentgenographic evidence of cardiomegaly (87 percent); an electrocardiographic abnormality (80 percent), most frequently in the form of left ventricular conduction delay; symptoms of cardiac failure (73 percent), and systemic emboli (4 percent). During the follow-up period, the frequency of these clinical manifestations, particularly cardiac failure and systemic emboli, increased.

With respect to systemic emboli (Table II), 103 patients were not taking anticoagulant agents during some period of the study; 23 episodes of systemic emboli occurred during this time in 19 patients (18 percent of this group). Of the patients with systemic emboli, 16 had one embolic episode, 2 had two episodes, and 1 had three episodes. After the initial clinical manifestation of dilated cardiomyopathy, 12 of the embolic episodes occurred in the 1st year, 5 between 2 and 4 years, 3 between 5 and 9 years, and 3 after 10 or more years. Thirty-two patients were taking anticoagulant agents during some period; no systemic emboli developed during this time. Because the years of exposure were greater for the group not taking than for the group taking anticoagulant therapy, statistical analysis incorporated the number of embolic events per 100 patients per year of exposure. Approximately four embolic events per 100 patient-years occurred in the group without anticoagulant therapy and none in the group with such therapy ($p < 0.05$). A second predisposing factor for systemic emboli appeared to be the presence of atrial fibrillation (Table II). Systemic emboli developed in 33 percent of the patients who had atrial fibrillation, but in only 14 percent of patients without atrial fibrillation; however, this difference did not reach statistical significance. There were no additional clinical or hemodynamic variables that were predictors of systemic embolism.

TABLE II

Systemic Emboli

	Patients With Emboli		Patient-Years of Exposure	Events per 100 Patient-Years (n)
	n	%		
Treatment with anticoagulant agents				
Yes (n = 32)	0	0	101	0
No (n = 103)	19	18	624	3.5
Atrial fibrillation				
Yes (n = 24)	8	33	. . .	. . .
No (n = 80)	11	14	. . .	. . .

Hemodynamic features: Cardiac hemodynamic evaluation at the time of diagnosis revealed a left ventricular end-diastolic pressure greater than 15 mm Hg in 81 patients (78 percent) and a cardiac index of less than 2.5 liters/min per m^2 in 65 patients (62 percent). One or the other abnormality was found in 96 patients (92 percent).

Clinical Course and Prognosis

At the time of the last follow-up analysis, 80 patients (77 percent) had died, and the majority of deaths (two thirds) occurred within the first 2 years (Fig. 1). The survival curve for the 24 remaining patients (23 percent) was comparable with that of the control group matched for age and sex. In the 24 living patients, chest roentgenograms were obtained both at the time of diagnosis and at the time of the last follow-up examination. Of these patients, 17 had a cardiothoracic ratio greater than 0.50, whereas at the time of the last follow-up analysis, 18 patients had either a normal or decreased cardiac size compared with the initial assessment (Fig. 2). In addition, comparison of the symptoms with those present at the time of diagnosis showed that only 3 of the 24 patients had had subjective deterioration and all of the others had had improvement or no change in symptoms.

Univariate analysis of prognostic factors: Because all patients were followed up for at least 6 years and most deaths occurred within that time, we evaluated the prognostic factors for the 6 year clinical course. Evalu-

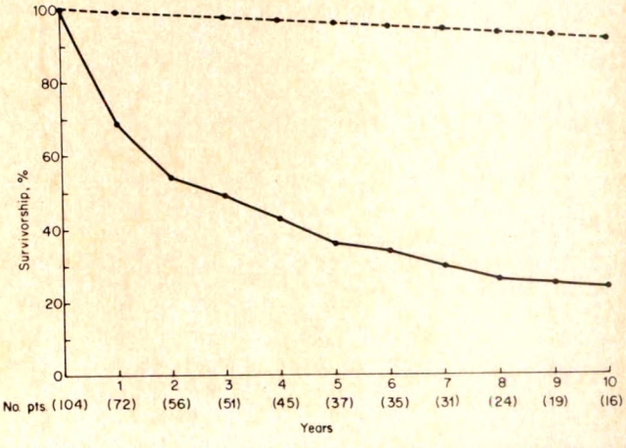

FIGURE 1. Observed survival plotted against time in years in 104 patients (pts.) with the diagnosis of idiopathic dilated cardiomyopathy (**solid line**). The **dashed line** represents the control expected survival, on the basis of age and sex distribution, according to the death rates of the Minnesota 1970 White Population Life Table. The number of alive patients under observation at each follow-up interval is indicated in parentheses.

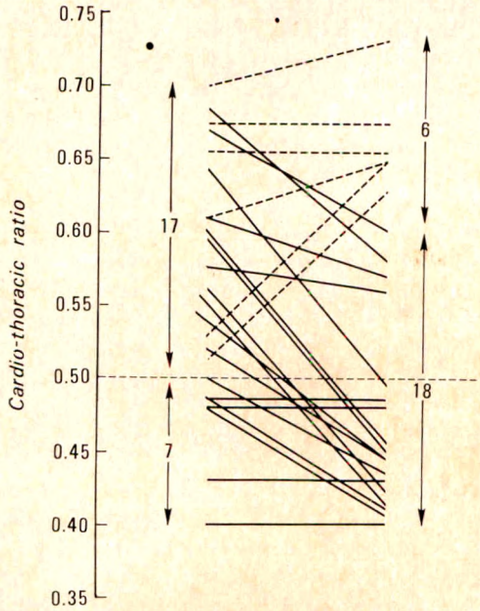

FIGURE 2. Roentgenographic cardiothoracic ratio at the time of diagnosis (**left end of lines**) and at the time of last follow-up examination (**right end of lines**) (median interval 10 years) in the 24 living patients. The **solid lines** represent patients who had a normal or reduced cardiac size at last follow-up analysis; the **dashed lines** represent those in whom the degree of cardiomegaly remained unchanged or had progressed.

ation at the time of diagnosis revealed only four factors that were independently and significantly predictive (Table III): (1) Age of the patient. The older the patient, the higher the probability of death; we arbitrarily chose age 55 years as a good discriminative age because patients aged 55 years or older had a mortality rate of 97 percent. (2) Cardiothoracic ratio calculated from the chest roentgenogram. The higher the cardiothoracic ratio, the higher the probability of death; arbitrarily, we selected 0.55 as a good discriminative cardiothoracic ratio, inasmuch as the mortality was 86 percent in patients with a ratio of 0.55 or more but only 40 percent in patients with a ratio of less than 0.55. (3) Cardiac index. The lower the cardiac index, the higher the probability of death; arbitrarily, we chose 3 liters/min per m^2 as a good discriminative cardiac index because the mortality rate was 89 percent in patients with a lower cardiac index but only 35 percent in those with an index of 3 liters/min per m^2 or greater. (4) Increased left ventricular end-diastolic pressure. The higher the pressure, the higher the probability of death; we arbitrarily chose 20 mm Hg as a good discriminative value because the mortality rate was 87 percent in patients with a pressure of 20 mm Hg or higher.

TABLE III

Prognostic Factors

Factors	p Value*	Division Point†	Dead (%)	Alive (%)
Age (yr)	<0.01	≥55	97	3
		<55	66	34
Cardiothoracic ratio	<0.01	≥0.55	86	14
from chest roentgenogram		<0.55	40	60
Cardiac index	<0.001	<3.0	89	11
(liters/min per m^2)		≥3.0	35	65
LVEDP (mm Hg)	<0.05	≥20	87	13
		<20	63	37

* Univariate analysis, level of significance. † Arbitrarily chosen. LVEDP = left ventricular end-diastolic pressure; p = probability

Linear discriminant analysis of prognostic factors: Stepwise linear discriminant function analysis of all the prognostic factors at the time of diagnosis (age, cardiothoracic ratio, cardiac index and left ventricular end-diastolic pressure) showed that with the combination of cardiac index and cardiothoracic ratio, 86 percent of the patients could be correctly classified with respect to 3 year survival.

Possible Etiologic or Risk Factors

In an attempt to determine risk factors that might disclose the underlying cardiomyopathy or contribute to its development, we found, in decreasing order of frequency, the following factors, singly or in combination: (1) excessive consumption of alcohol (21 percent of the patients); (2) a severe influenza-like syndrome shortly before the first clinical manifestation of cardiomyopathy (20 percent; the syndrome recurred in only two of these patients); (3) a clinical history of rheumatic fever, without apparent involvement of the cardiac valves, 15 to 35 years before the first clinical manifestation of cardiomyopathy (8 percent); (4) postpartal cardiomyopathy (3 percent; none of these patients and only one in the total group had a repeated pregnancy); and (5) familial cardiomyopathy (2 percent). In 49 percent of the patients, no apparent risk factors were found.

Statistical analysis of the presence or absence of each of these risk factors revealed no prognostic significance. However, among the 22 patients with excessive consumption of alcohol, all 4 patients who are alive have completely abstained from alcohol, compared with only 8 of the 18 patients who died. This difference was not statistically significant.

Discussion

This review, which is primarily a study of the natural history of idiopathic dilated cardiomyopathy, is unique. The study group consists of a medical series in which the diagnosis was confirmed at cardiac catheterization in all patients and in which the duration of follow-up analysis is the longest thus far reported.

Problems in Selection of Patients

Two aspects underlying the selection of these patients should be emphasized.

1. The number of patients entered into this study during the 14 year period (1960 through 1973) was relatively small (104 patients) even though the incidence of this disease appears to be high.[8] This analysis is retrospective, and a prerequisite for entry was ventriculographic evidence of cardiomyopathy. In the early 1960s, cardiac catheterization was less commonly per-

formed than in the 1970s, thus limiting the patient population potentially available for inclusion in the study. Consequently, the study group is highly selected but well defined.

2. In 44 of the 104 patients, the coronary anatomy was not defined by arteriography or at autopsy. However, significant coronary artery disease was highly unlikely in these patients for the following reasons: First, none had clinical, electrocardiographic or ventriculographic features of coronary artery disease. Second, the natural history of these patients was almost identical with that of the 60 patients in whom the absence of appreciable coronary artery disease was proved at arteriography or autopsy, and both groups had similar clinical, electrocardiographic and ventriculographic features. These findings strongly suggest that the 44 patients did not have significant coronary artery disease or "ischemic cardiomyopathy," [9] although this cannot be categorically excluded.

Clinical and Hemodynamic Features

Our study and others[8,10,11] show that features of left- or right-sided heart failure are not necessarily the initial clinical manifestations of the disease. The term *dilated cardiomyopathy* aptly describes the initial ventriculographic features of left ventricular dilatation and a diffuse, global decrease in amplitude of contraction. Nevertheless, perhaps in the future, identification before the development of ventricular dilatation, either clinically,[12] echocardiographically[13,14] or radioisotopically,[15,16] will enable earlier and possibly more successful therapeutic intervention.

This and other studies[11,17–21] illustrate that during the later stages of the disease, heart failure, cardiomegaly and electrocardiographic abnormalities almost invariably occur. Hemodynamic correlates were identified by cardiac catheterization in that almost all of the patients had a high left ventricular end-diastolic pressure and a low cardiac index. By definition, left ventriculograms were abnormal in all patients, revealing a global decrease in contractility suggestive of generalized myocardial involvement.

Systemic embolism: The large incidence of systemic emboli found in our patients is a well established clinical observation.[8,10,17–19,22] Autopsy studies have demonstrated that such emboli arise from a thrombus attached to the underlying diseased left ventricular endocardium[8,17,19,22] or, in some cases, from a left atrial thrombus.[17] In our patients we noted that over half of the systemic embolic episodes occurred within the 1st year of the initial clinical manifestation of cardiomyopathy and, although the total incidence decreased with time, this appeared to be mostly a function of the decreasing number of surviving patients.

Role of atrial fibrillation and anticoagulant therapy: Univariate analysis of the various hemodynamic and clinical features revealed that only the presence of atrial fibrillation appeared to show some predictive value for systemic emboli. However, the 32 patients who received anticoagulant therapy had no systemic embolic episodes during the period of anticoagulation. This finding, which was statistically significant, appears to be of great therapeutic relevance. That is, it suggests that in patients with dilated cardiomyopathy, oral administration of anticoagulant agents may help prevent systemic embolism. Our current policy is to prescribe long-term anticoagulant therapy in all of these patients unless a specific contraindication exists. None of our patients who were treated with anticoagulant agents had major hemorrhagic complications.

Clinical Course and Prognosis

This group of patients with dilated cardiomyopathy had either an accelerated course to death (77 percent of patients) or a striking improvement or stabilization (23 percent). Thus, of the patients who died, two thirds died within the first 2 years after diagnosis. In contrast, the condition of most remaining patients has subjectively improved or stabilized and, their heart size is normal or smaller.

The strikingly different prognoses in these two patient groups could reflect the specific nature and severity of the initial cardiac insult and its "tolerance" by the heart. Our data conform with those of others[8,10,11,21–23] suggesting that the more severe the clinical and hemodynamic manifestations at the time of diagnosis, the worse is the long-term prognosis. Not surprisingly, a severe initial cardiac insult with its attendant consequences of substantial cardiomegaly, low cardiac index and high left ventricular end-diastolic pressure does identify a group of patients with an unfavorable outcome leading to early death.

Kristinsson,[11] in a shorter follow-up analysis of patients seen at the Hammersmith Hospital in London, also noted a high mortality rate within the first 2 years after the clinical diagnosis. Recently, Segal et al.[10] recorded a less dramatic initial mortality rate. Their patient population differed from ours in that it was highly selected, excluding patients with excessive alcohol intake, possible viral myocardial disease or viral myopericarditis and those with peripartal cardiomyopathy. Furthermore, because diagnostic cardiac catheterization was not a specific requirement in their study, many of the inpatients did not fulfill our stringent hemodynamic and angiographic criteria for cardiomyopathy. Since in our study most patients were treated with digoxin or diuretic agents or both, the prognostic value of such treatment could not be analyzed. In addition, because only patients seen between 1960 and 1973 were entered into the study, the new approach of afterload reduction with vasodilating agents could not be assessed.

Etiologic and Therapeutic Considerations

Because the definition of idiopathic dilated cardiomyopathy is "heart muscle disease of unknown causes," a semantic argument is introduced when potentially etiologic agents are discussed. Once the cause of a specific form of cardiac muscle disease is established, on the basis of this definition, the term *cardiomyopathy* should no longer be used. In agreement with Goodwin,[6] we believe that idiopathic dilated cardiomyopathy is

probably the result of several factors acting in concert in a susceptible person. Thus alcohol, viral infections, puerperium and other conditions should currently be regarded only as possible risk factors; whether these conditions potentiate the underlying cardiomyopathy, unmask it or act as causative agents in their own right is unclear. In most cases, neither light microscopy nor ultrastructural studies identify a single causative agent.[6,24]

Alcohol: A link between excessive alcohol intake and cardiomyopathy has been alluded to frequently in the past,[24–28] but its precise role or mechanism of action is not fully understood.[27,28] In 21 percent of our patients, we identified an excessive consumption of alcohol according to criteria defined by others.[25,27,29–32] Our findings support previous observations[32,33] that alcohol may be deleterious in any patient with cardiomyopathy and that complete abstinence from alcohol may be beneficial in some patients. Whether alcohol acts as a primary causative agent cannot be established from our data, but it appears that in the presence of diffuse myocardial disease, alcohol is an added insult best avoided.

Viral infection: It is tempting to incriminate viral infection as a cause of cardiomyopathy. Twenty percent of our patients had a severe influenza-like syndrome shortly before the first manifestation of cardiomyopathy. In a recent prospective study,[34] a similar influenza-like syndrome occurring shortly before the initial symptoms of cardiomyopathy was reported in 10 of 18 patients. A relation between viral infection and cardiomyopathy is suggested by several other studies,[34–42] but complete evidence is still lacking.

Other contributing factors: In some of our patients in this study, possible contributing factors were rheumatic fever, puerperium and a family history of cardiomyopathy. The frequency of a convincing history of rheumatic fever (8 percent of our patients) was too high to be merely coincidental; it is not certain whether these patients were affected by chronic or recurrent rheumatic myocarditis that led to the dilated cardiomyopathy or whether the early rheumatic process had altered the myocardial immunologic response and thus predisposed the patients to cardiomyopathy. The development of dilated cardiomyopathy during pregnancy or in the puerperium has been noted previously[11,43–46] but was present in only three of our patients. A family history of idiopathic dilated cardiomyopathy is rare[11,47,48] and was present in only 2 of our 104 patients. Although a positive family history of cardiomyopathy and the puerperium may be factors in the genesis of cardiomyopathy, the intrinsic mechanism remains unknown.

Implications: It appears reasonable to consider dilated cardiomyopathy the final common pathway of many different disorders. Future investigations will probably focus on patients identified at an earlier stage of the disease. At a minimum, these studies should include (1) prospective and systematic observations in various populations of the risk factors and the natural history of the disease (such as defined in this retrospective study), and (2) serial myocardial biopsy for the assessment of histologic and ultrastructural changes, as well as cell and serologic identification of possible ongoing infectious and immunologic processes. Such studies, aiming for a better understanding of the underlying cause or causes during the early stages of the disease, may reveal meaningful methods of prophylaxis and treatment.[49–52]

Prognosis in Hypertrophic Cardiomyopathy: Role of Age and Clinical, Electrocardiographic and Hemodynamic Features

WILLIAM McKENNA, MD*

Retrospective analysis of the clinical course of 254 patients with hypertrophic cardiomyopathy, followed up for 1 to 23 years (mean 6), disclosed that 58 had died, 32 of them suddenly. The 196 survivors were compared with the 32 patients who died suddenly and with the 38 who died suddenly or with heart failure. The combination of young age (14 years or less), syncope at diagnosis, severe dyspnea at last follow-up and a family history of hypertrophic cardiomyopathy and sudden death best predicted sudden death (false negative rate 30 percent, false positive rate 27 percent). A "malignant" family history was associated with poor prognosis, particularly in the younger patients; a family history of hypertrophic cardiomyopathy without sudden death was more frequent in the survivors (12 percent) than in the dead (5 percent). Patients who had a diagnosis in childhood were usually asymptomatic, had an unfavorable family history and a 5.9 percent annual mortality rate. In those aged 15 to 45 years at diagnosis, there was a 2.5 percent annual mortality rate and syncope was the only prognostic feature. Among those diagnosed between age 45 and 60 years, dyspnea and exertional chest pain were more common in the patients who died, and the annual mortality rate was 2.6 percent. Poor prognosis was better predicted by the history at the time of diagnosis and by changes in symptoms during follow-up than by any electrocardiographic or hemodynamic measurement.

Hypertrophic cardiomyopathy, first recognized clinically by Brock,[1] was characterized by Goodwin et al.[2] and Braunwald et al.[3] At the Royal Postgraduate Medical School sudden death was the most common mode of death.[4] The purpose of this study is to relate specific clinical, electrocardiographic and hemodynamic features to prognosis and to examine the evidence that a family history of the disease,[4] blackouts[5] and diagnosis in childhood[6] were of ill omen.

Methods

Study patients: Retrospective analysis to assess the prognostic value of clinical, electrocardiographic and hemodynamic features at diagnosis and clinical features at last follow-up was performed on 254 patients with hypertrophic cardiomyopathy who were diagnosed and followed up at the Royal Postgraduate Medical School. Although noncardiac and cardiac surgical deaths are discussed, the comparative analysis included only those patients who died with heart failure or suddenly. The clinical information was always taken from observations by one of us.

The diagnosis of hypertrophic cardiomyopathy was based on typical clinical features,[2,3] M mode echocardiography[7] and left ventricular angiography.[8] In 228 patients the diagnosis was established by left ventricular angiography. Twenty-six patients were diagnosed noninvasively: Ten patients were first degree relatives of propositi and had clinical, electrocardiographic or echocardiographic features consistent with hypertrophic cardiomyopathy, whereas 16 patients had the typical clinical and echocardiographic features of hypertrophic cardiomyopathy and a left ventricular outflow tract gradient.[3,7,9] We do not believe that hypertrophic cardiomyopathy without a gradient can always be clinically or

echocardiographically differentiated from secondary forms of left ventricular hypertrophy, and therefore we performed angiography in all such patients.[10]

Mode of diagnosis: Since the diagnostic use of M mode echocardiography became widely available in the early 1970s, the bias of selection of patients may have changed; we therefore examined why investigations were performed in our patients. Diagnosis was made between 1957 and 1972 in 140 patients and since 1972 in 114 patients. Two hundred forty-one of the patients were studied for evaluation of symptoms, the presence of a systolic murmur, an abnormal apex beat or an abnormal electrocardiogram. In 10 patients diagnosis was made during the evaluation of first degree relatives of propositi. An additional 26 living and 32 dead family members of propositi have or had definite or probable hypertrophic cardiomyopathy; they are not, however, included in the analysis because of incomplete diagnostic or follow-up information. In three patients diagnosis was made after investigation for clinical features suggestive of mitral stenosis[11]; in these patients a clinically unsuspected diagnosis of hypertrophic cardiomyopathy was made by echocardiography. There were, however, no other patients in whom initial referral or diagnosis of hypertrophic cardiomyopathy was based solely on the echocardiogram. Our evaluation of M mode echocardiography in prognosis was previously published.[12]

Follow-up: Sixty-nine percent of the patients were seen on a follow-up examination within 2 years before the study; 16 patients were excluded because they had no follow-up for at least 5 years before the analysis. One hundred fifty-two patients were male and 102 were female. The age at diagnosis was 1 to 66 years (mean 34). The length of the follow-up period was 1 to 23 years (mean 6). We were unable to obtain retrospective information on the influence of beta adrenergic blocking therapy on prognosis because our policy had been to treat all patients with hypertrophic cardiomyopathy with beta blocking agents.

The electrocardiogram recorded at the time of diagnosis was evaluated for rhythm disturbances, particularly atrial fibrillation; conduction disease, including the P-R interval, the Q-T interval corrected for heart rate (Q-Tc = Q-T/R-R interval), left axis deviation (mean frontal QRS axis −30° to −150°) and bundle branch block[13]; left or right atrial enlargement[13]; and voltage criteria of left ventricular hypertrophy.[14]

Left heart catheterization had been performed in 228 patients, and 198 of the patients had also undergone right-sided hemodynamic study. Patients were considered to have a left ventricular outflow tract gradient if the pressure gradient measured under basal conditions or with provocation (at first with isoproterenol infusion, later with amyl nitrate inhalation or the Valsalva maneuver) was 20 mm Hg or greater.

Analysis of data: A stepwise discriminant analysis was performed to compare the patients who died with heart failure or suddenly, or both groups, with the survivors; 24 clinical, electrocardiographic and hemodynamic features were used as independent variables. The chi-square test or, when appropriate, Fisher's exact test was used for qualitative comparison and the *t* test was used for quantitative comparison of clinical, electrocardiographic and hemodynamic features of the survivors and the dead. Cumulative survival rates were derived from life table calculations.[15]

Results

Age and family history: Fifty-eight patients (23 percent) had died, 6 (11 percent) from cardiac failure and 32 (55 percent) suddenly. All 32 sudden deaths were unexpected; 24 were witnessed and were instantaneous; in the remaining 8 cases, the patient was found dead. In the remaining 20 patients, death was due to cerebral embolus (one patient, 2 percent), infective endocarditis (two patients, 3 percent), cardiac surgery (nine patients, 15 percent), noncardiac causes (seven patients, 12 percent) and accident during electrophysiologic study (one patient, 2 percent). The mean age at diagnosis was 30 years (range 3 to 66), which was significantly lower than that of the 196 survivors ($p < 0.03$). Eleven of the dead patients were aged 14 years or younger at the time of diagnosis (Table I). The duration of follow-up was 5.7 ± 5.3 years in the survivors and 6.2 ± 4.8 years in the dead (Table I). The age at death was 7 to 67 years (mean 37); 12 (31 percent) of the dead patients were aged 30 years or younger at the time of death. The six patients who died with heart failure were aged 14 to 66 years (mean 38) when they died.

Nine (24 percent) of 38 patients who died suddenly or with cardiac failure had a positive family history of hypertrophic cardiomyopathy and unexplained sudden death compared with 23 (12 percent) of the survivors ($p = 0.06$). In childhood an unfavorable family history was associated with sudden death ($p < 0.01$): 4 of the 11 patients who died had at least one, and three had more than one, first degree relative who died from hypertrophic cardiomyopathy. Although 29 percent of the patients who died had a first degree relative with hypertrophic cardiomyopathy, so did 24 percent of the survivors (Table II).

Symptoms: The symptoms at the time of diagnosis in the patients who are dead and the survivors are compared in Table III. Severe dyspnea (New York

Heart Association functional class III or IV) was uncommon and did not predict poor prognosis. Although more dead patients had dizziness, only syncope ($p < 0.05$) was associated with death.

Electrocardiography: Table IV summarizes the comparison of the electrocardiogram at the time of diagnosis in the living patients and those who had died: 4 percent of the survivors and 11 percent of the dead had atrial fibrillation (this difference was not significant), and the mean P-R interval and the mean corrected Q-T interval were almost identical in both groups. Overt preexcitation was present in five patients (2 percent); another patient with concealed Wolff-Parkinson-White syndrome died during electrophysiologic study when atrial pacing initiated ventricular tachycardia that degenerated to ventricular fibrillation.[16] Although complete bundle branch block was rare, incomplete bundle branch block was present in 20 (10 percent) of the survivors and 9 (24 percent) of the dead and was associated with a worse prognosis ($p < 0.04$). The voltage criteria for left ventricular hypertrophy were present in 67 percent of the survivors and 69 percent of the deceased, and the difference in mean voltage amplitude in the two groups was not significant.

Hemodynamics: Table V presents a hemodynamic comparison of the living and dead patients using data from the original diagnostic catheterization study. The mean right atrial, pulmonary capillary wedge and left ventricular end-diastolic pressures were similarly elevated in both groups. Sixty-six percent of the patients who died and 63 percent of the survivors had a resting or provocable left ventricular outflow tract gradient, and neither the presence nor the absence of a gradient predicted subsequent mortality.

The prognostic significance of clinical, electrocardiographic and hemodynamic features in relation to the age at diagnosis is assessed in Tables VI to VIII. No hemodynamic or electrocardiographic feature was associated with death; however, syncope in patients less than 45 years of age indicated a poor prognosis ($p < 0.01$). Exertional chest pain and dyspnea were more common in the older patients who died (more than 45 years) than in the older survivors.

Symptoms at last follow-up study: Table IX compares the clinical features at the last follow-up exami-

TABLE IV

Electrocardiographic Comparison of 196 Survivors and 38 Patients Who Died

	Electrocardiographic Findings at Time of Diagnosis							
	AF (%)	Atrial Enlargement (%)	$\overline{P\text{-}R}$ (s)	$\overline{Q\text{-}Tc}$ (s)	BBB (%)	LAD (%)	R in aVL (mean) (mm)	S in V_1 + R in V_5 (mm)
Alive	4	47	0.17	0.43	3	31	11.2 ± 8.8	40.0 ± 18.0
Dead	11	42	0.16	0.43	3	22	10.9 ± 7.1	39.7 ± 18.6

AF = atrial fibrillation; atrial enlargement = left atrial or right atrial enlargement, or both; BBB = bundle branch block; LAD = left axis deviation P-R = mean P-R interval; Q-Tc = mean Q-T interval corrected for heart rate; R in aVL = mean R wave amplitude in lead aVL; S in V_1 + R in V_5 = mean sum of the S wave amplitude in lead V_1 and the R wave amplitude in lead V_5.

nation in the survivors and the patients who died. The incidence of symptoms at follow-up was lower than that at diagnosis; although more of the dead patients had syncope and dizziness, only severe dyspnea (New York Heart Association class III or IV) ($p < 0.05$) was associated with a poor prognosis.

Predictors of sudden death: Discriminant analysis disclosed that the combination of the following features best predicted sudden death: young age (14 years or less) and syncope at diagnosis, a positive family history of hypertrophic cardiomyopathy and sudden death, and severe dyspnea (functional class III or IV) at last follow-up examination. Sixteen of 23 dead patients (false negative rate 30 percent) and 111 of 163 survivors (false positive rate 27 percent) were correctly identified. When the deaths from heart failure (six patients) were included with the sudden deaths, the combination of young age (14 years or less), congestive heart failure and syncope at diagnosis, severe dyspnea at last follow-up examination, conduction defects (incomplete or complete bundle branch block) and left or right atrial enlargement on electrocardiography best predicted mortality. The outcome in 21 of the 30 dead patients (false negative rate 30 percent) and 133 of the 160 survivors (false positive rate 17 percent) was correctly predicted by the analysis.

Role of surgery: The initial treatment at the time of diagnosis and the current therapy are summarized in Table X. Digoxin was used to treat patients with heart failure and atrial fibrillation. Apart from verapamil and beta adrenergic blocking agents, only 7 percent of the 254 patients ever received antiarrhythmic drugs. Thirty-three patients had undergone myotomy-myomectomy or mitral valve replacement, or both (27 patients before 1975), and 9 of these patients died perioperatively. The annual mortality rate in the surgical survivors was 1.8 percent. Six of the 24 patients who survived the operation subsequently died 1 to 20 years (mean 6) after the operation (1 from documented ventricular fibrillation, 3 suddenly, 1 with heart failure and another in an accident). Although a resting or provo-

cable gradient of at least 30 mm Hg was an essential requirement for operation in all patients, the symptomatic indications for operation have varied. Before 1970 the preoperative symptom status of the surgical patients was similar to that of the medical patients. However, with improved symptomatic treatment in the past 10 years, proportionately fewer patients have been operated on and these have been severely symptomatic with poor response to medical therapy.

Discussion

Sudden death in hypertrophic cardiomyopathy: Our results confirm the impression that sudden death is the most common mode of death in patients with hypertrophic cardiomyopathy.[17] The patients who died were significantly younger at the time of diagnosis than the survivors, and 12 were aged 30 years or younger when they died. The annual mortality rate in the pediatric age group was 5.9 percent (Fig. 1). This is consistent with the findings in a retrospective study in which 18 of 26 patients who died suddenly were aged 20 years or younger and with the findings of a high annual mortality rate (4 percent) in children with hypertrophic cardiomyopathy.[18] Compared with the older patients (Table VI) children have a greater incidence of syncope; however, they are otherwise less symptomatic. The children who died were clinically and electrocardiographically similar to the survivors (Tables VI and VII); their mean filling pressures were similar, and fewer patients who died had a left ventricular outflow tract gradient (Table VIII). Diagnosis in childhood was also associated with a family history of hypertrophic cardiomyopathy and sudden death ($p < 0.01$). Maron et al.[19] described a subgroup of families with malignant hypertrophic cardiomyopathy in which the incidence of premature death was unusually high. In our study 4 of the 11 dead patients whose diagnosis had been made in childhood had at least one first degree relative who died from hypertrophic cardiomyopathy, and 3 of the 4 had more than one relative who had died from hypertrophic cardiomyopathy.

TABLE X

Medical Treatment of 254 Patients With Hypertrophic Cardiomyopathy

Drug	At Diagnosis (%)	At Last Follow-Up (%)
Digoxin*	11	16
Diuretic drug	13	27
Beta blocking agent	67	68
Verapamil	2	4
Antiarrhythmic agent	5	5

* Digoxin was used to treat heart failure and to slow atrioventricular conduction in patients with atrial fibrillation.

Role of family history: A family history of sudden death with or without documented hypertrophic cardiomyopathy was associated with a poor prognosis ($p < 0.05$), despite the bias of patient selection. This did not take into account 32 dead members of "malignant" families who probably had hypertrophic cardiomyopathy but in whom diagnostic or follow-up documentation was inadequate. Twenty-five percent of the patients who died had a positive family history of hypertrophic cardiomyopathy and sudden death, and six of these nine patients who died had multiple sudden deaths in their families. Malignant hypertrophic cardiomyopathy is characterized by sudden death in young asymptomatic patients.[19] In contrast to these "malignant" families were "benign" families with affected members but no sudden deaths; only 2 of 24 propositi of such families died suddenly or in heart failure. Patients with a family history of hypertrophic cardiomyopathy without sudden death had a prognosis similar to that in patients with no family history of hypertrophic cardiomyopathy.

Effect of medical treatment: From the data available we cannot assess the effect of medical treatment, particularly of beta adrenergic blocking drugs. In a prospective nonrandomized study Frank et al.[20] administered "complete" beta receptor blocking doses of propranolol (average dose 462 mg/day) and found improvement in symptoms and no mortality in 22 patients followed up 2 to 8 years (mean 5); in contrast, 4 of 10 control patients died suddenly. Although beta-adrenergic blocking drugs improve symptoms, the effect on prognosis is uncertain and requires further study.

Recently, Rosing et al.[21] reported relief of symptoms and improved exercise capacity in patients with hypertrophic cardiomyopathy treated with the calcium antagonist verapamil. These results are consistent with reports of symptomatic improvement, reduction in heart size (assessed radiographically) and reduced QRS amplitude in the electrocardiogram after large dose (480 to 720 mg/day) long-term treatment with verapamil.[22] Long-term prospective randomized studies of verapamil treatment in hypertrophic cardiomyopathy are needed to assess the effect on prognosis.

Effect of surgical treatment: Although the surgical mortality rate was high, the small number of patients, the changing bias of patient selection and use of different surgical techniques make it difficult to assess the effect of surgical treatment on prognosis. However, the subsequent annual mortality rate in the surgical survivors was 1.8 percent, similar to that in the series with the largest number of surgical survivors (1.8 percent),[23] and less than the annual mortality rate in the medically treated patients (3.5 percent). Nevertheless, because of the high overall operative mortality rate (approximately 27 percent), the total 6 year mortality rate for surgically treated patients exceeded that of medically treated patients.

Predictive importance of the clinical features: A poor prognosis was better predicted by the patient's history than by any electrocardiographic or hemodynamic measurement. At the time of diagnosis older patients were more symptomatic (Table VIII) but

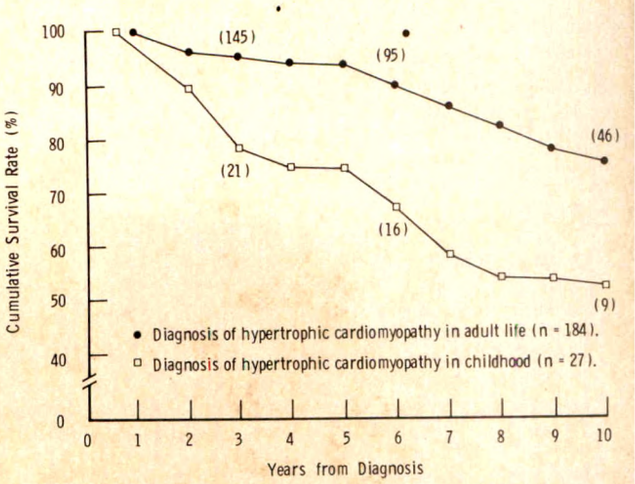

FIGURE 1. Cumulative survival curve from the year of diagnosis for 211 medically treated patients. The probability of death = the total number of deaths for the year divided by the adjusted number at risk, minus the number of deaths due to other causes.[15]
